To ensure myself a good long day I left London by the 9.15 A.M. train and reached Tring punctually at half-past ten, where I found Mr. Sanders, the genial and talented gardener, waiting to take me under his wing. From the station we drove through the town of Tring, past Lord Rothschild's beautiful demesne, through the country for about four miles, until we came to one of the entrances of the Halton estate. Instead of going direct to the gardens we went round and round until we

had formed more, so far as I could see, to give work to some of the labourers about than for any advantages that could possibly accrue to him from it. Facing this stands a very beantiful châlet, which has been erected as a resting place for players in the American bowling alley to which it is attached. It is indeed a charming spot, the views from both back and front being almost incomparable, at least to those who love English scenery.

From thence we drove down grass drives through shady woods of Beech trees, between which could be caught at intervals glimpses of the mansion lying far away down in the valley below. Through one of these vistas was opened a view of the flower gardens, and the picture was a perfect one, worthy of being reproduced on canvas by any of our most celebrated artists. During the drive down the hills several rustic summer houses were passed. These erections, I was surprised to

see, were, though rustic outside, not by any means so in, the floors being thickly carpeted, and comfortable looking chairs standing about, adding an air of cosiness to them which is all too often conspicuous by its absence in these useful and ornamental additions to a garden. A long drive through the park brought us to the kitchen and fruit gardens, which are situated rather over a mile from the mansion and flower gardens. It is in this part of the estate that Mr. Sanders' pleasant house is situated, almost hidden under some old Beech trees, and close beside an orchard which has been but very recently planted. Here we stayed and had a thoroughly good rest, took some substantial refreshment for the welfare of the body, and then away we started to walk through the park to the flower gardens, which are unusually extensive.

The gardens round the mansion are composed of lawns and flower beds, all of which are kept scrupulously clean, and have been during the past summer heavily watered, which, as evidenced by the bright and robust condition of the plants, has had a most beneficial effect. The terrace beds are filled with tuberous and fibrous-rooted Begonias, Fuchsias, and Zonal Polargoniums, all the varieties planted being conspicuous for their bright colours. The Begonias have not flowered so freely as is customary, the soil, which is of a very chalky nature, not having held enough moisture to insure the utmost floriferousness. There were, however, two strikingly notable exceptions to this, and they both belonged to the fibrous-rooted section; one was B. Worthiana, and the other B. fioribunda rosea, the former being covered with its bright orange-coloured blossoms, and the latter forming a perfect mass of rosy pink. Down the centre walk from the garden entrance to the house beds and vases on each side look very bright, and at the end is a large circular fountain, round the back of which is a bright border containing Eucalyptus globulus (Blue Gum), Castor Oil Plants, Palms, Cannas, Nicotiana affinis, Marguerites, and Zonal Pelargonium John Gibbons. On each side of this fountain, partially hidden in the background of bushes, is a newerful electric light, with the reflectors fixed to shine directly and is a powerful electric light, with the reflectors fixed to shine directly on the centre ornament. The pedestals on which the vases are stood in the walk are made so that the lower portion swings back, and in each is found an electric light; this throws its light straight down the walk towards the fountain, and the effect thus produced when the lights are burning is, said Mr. Sanders, truly magnificent. The beds, vases, and fountains with their occupants are as clearly seen by this artificial light by night as they are by day under the natural rays of the sun. These vases are filled with Begonias and various other plants, amongst the best being those occupied by double white and pink Zonal Pelargoniums, which are flowering with exceptional freedom.

We next visited the Italian garden, where a most emphatic change The centre is a lawn with one large centre bed, and the greets the eye. sides are of trellis, up which Ivy has been trained. Niches have been made in which statues are placed, and at the extreme end is a large summer house, over which Roses are being trained. The bed in the middle of this garden is a large one filled with Lilium longiflorum, L. tigrinum splendens, yellow Marguerites, and some excellent Fuchsias. This Italian garden is one of the most novel features of the estate, and for lovers of the uncommon certainly one of the most attractive. For my own part, however, I prefer the style so well portrayed in what is known as the German garden, where the beds are formed of large masses of a few different plants, planted in a manner which needs an inspection to be understood, as for me, at any rate, it is practically indescribable. Dark and light-foliaged Cannas are in this style of planting seen to advantage, as also are the Begonias, amongst which Acacia lophantha has been planted, Centaurea Clementei, and Abutilons. The Indian garden represents an entirely different mode of planting, the pre-dominating features throughout being handsome Palms and Dracænas of all sizes. These might be termed the background, but flowers of various sorts were used to form attractive beds and borders. A tent is erected in the Indian style in this garden, and forms an unusual feature in a flower garden, being furnished in a really luxurious manner. Stands are fixed in here, as in almost all the other structures on the estate in which flowers and plants may be placed, and these, it is needless to say are effective. An unique attraction on one of the lawns is a huge wicker basket filled with plants of different kinds. It is of immense size, measuring about 14 feet across and standing upwards of 5 feet high, the cross handle, of course, rising much higher than this. I was much struck with the beauty of this ornament, and have never before seen such a thing. The basket is lined with turves, grass side outwards, and in this is placed a casing, which carries the weight of the soil. The centre was bright with Lilium longiflorum and L. tigrinum splendens, grand Hydrangeas, Petunias, and Tropæolums, the latter being allowed to hang in festoons over the sides. The gardens surrounding an ornamental lake, which has been formed mainly to provide skating during the winter months, are very charmingly laid out. Liliums and Zonal Pelargoniums are largely utilised here, as also are shrubs of various kinds and of all sizes.

The kitchen and fruit gardens are also admirably kept, but the latter is completely overrun with wasps this season, and to such an extent do they carry their depredations that Mr. Sanders has found it absolutely necessary to have all the Pears gathered before they were nearly ripe, as they were all being rapidly destroyed. At the end of the garden runs an arm of the Grand Junction Canal, and in the banks of this the wasps make their homes, which are unfortunately rather difficult of access for the men to destroy them. Cyanide of potassium is, however, being used with fatal effects to many hundreds of the pests daily. All the small fruits have been gathered, but the trees and bushes bear the

unmistakeable stamp of being in good hands. A number of the Apple trees have been covered with hexagon netting to keep out the wasps, but if they are as precocious as those referred to by a Sussex correspondent at page 176 of your last issue this precaution will be of little use. All the best varieties of Apples are grown, and particularly noticeable were some trees of Cox's Orange Pippin, King of the Pippins, and Wellington, which were carrying crops of magnificent fruits. Strawberries are forced in very large numbers, and preparations are now in an advanced stage for supplying an abundance of fruits during the coming season. In the houses the same difficulty with the wasps has to be contended with, though not to quite such a large extent. Several vineries and Peach houses have been cleared of their fruit, as also have some Fig trees, for which there is a large demand. Notwithstanding the fruit that has been gathered, there is still abundance ripe and ripening, more especially amongst the Grapes.

The houses devoted to plants are completely filled with those suitable for furnishing the mansion and summer houses, Caladiums, Crotons, Dracænas, Anthuriums representing the largest stocks. Maidenhair Ferns are not largely grown in pots, though some are of course so cultivated, but the fronds when required are taken from the end wall of one of the vineries on which plants have been secured by the aid of a wire trellis. This, as will be readily admitted, besides supplying innumerable fronds, forms a most pleasing and at the same time novel appearance. Unfortunately my visit was too late for me to see the Souvenir de la Malmaison Carnations in their best condition, but some idea may be gained on referring to the illustration (fig. 29), which has been reproduced from a photograph, of the great beauty of the plants and the striking success of the mode of culture to which they are subjected. So grand are the plants and the few individual blooms which remained, that I asked Mr. Sanders to favour me with details of his mode of procedure, and he gives it as follows:—

"The house of Souvenir de la Malmaison Carnations in the photograph contains about 700 plants of the fleshy white and pink varieties, which, with the striped Lady Middleton, are the only three that can claim to be true types of that now popular flower. Their culture being generally well known by all who take an interest in Carnations, there is perhaps nothing new in our method of treating them. Layering, in preference to cuttings, is done in frames in July as soon as the plants are ready, shading them for a week or two until they commence to make fresh roots, when they are gradually hardened and exposed to the weather by removing the lights altogether. When well rooted the young plants are lifted and put in 48-size pots, using good loam, leaf mould, and sand. When well established in the soil they are again shifted into 32's, a little well decayed manure being used this time and at all succeeding pottings. No more shifts are given them during November, December, and January, when growth is naturally slow and root extension is not required. Watering is at that period very carefully done, and a dry atmosphere is maintained, with an even night temperature of 45° to 50°, and the plants being kept well up to the light.

"When the days begin to lengthen and the sun to regain its power Another notting is then given, the plants soon make new growth. Another potting is then given, which carries them through their flowering period, during which they are benefited by liberal treatment in the way of liquid manure waterings, and an occasional application of Clay's fertiliser. Soot, too, is an important factor in producing that deep leek-green foliage, indicating perfect health. One flower stem each is all to be expected the first flowering, but the plants are at the same time making side shoots close down to the soil. These shoots soon form a perfect cluster of growth, These shoots soon form a perfect cluster of growth, ensuring a good harvest of flowers the following year. After flowering, during which time shading is necessary, the plants are gradually exposed and stood outdoors for a week or two before being finally reported, this time in 10 or 11-inch pots, to allow the soil to be worked well around the loosened balls with their mass of roots. The plants are shaded and syringed a little to establish them in their new They soon grow into good bushes, with from eight to sixteen strong growths, the earliest of which flower during the winter and early spring. A little higher temperature is given to the earliest plants, 55 at night, which materially assists the development of the flowers. The wealth of bloom is not looked for until May and June, when the same liberal treatment is resorted to until the plants have done flowering. The plants represented in the engraving are two years old. To have an abundance of flowers it is necessary to raise plants every year from the two-year-old plants after flowering, there being no advantage in keeping them longer, unless extra size specimens are required. They at no time want coddling, and like plenty of light and air on all favourable occasions, shading only after potting and when in flower. No plant repays the cultivator better for liberal treatment when the blooms are developing, and flowers 4, 5, and even 6 inches across are the result.

"Like all other plants Carnations have their enemies, and a perpetual war is always raging to keep them under. Green fly is very persistent, and frequent fumigations are necessary to dislodge the pest. Red spider during hot dry weather is a still worse enemy; dipping or syringing with insecticides being resorted to to clear the plants of them, or sickly yellow foliage soon follows. But worst of all is the brown fungi, which infests the plants during the winter, for which I know no absolute cure. We keep it under by continually going over the plants and rubbing it off with a dull pointed stick, using a mixture of water, softsoap, and sulphur, which kills the spores when dislodged. While there is really no cure, I believe there is a preventive, which lies in the management of the plants during late summer and autumn, growing them well exposed to

the sun, which hardens every particle of growth, and avoiding a moist muggy atmosphere; but as we are situated on a level with a branch of the Grand Junction Canal we cannot well control the latter as much as we should like."—H. J. W.

WASPS.

The season proves exceptionally favourable for the development of wasps' nests, and many hornets have made their appearance once more after an absence of many years. There is a mistake on page 126 copied from a contemporary, in supposing that wasps "develop from eggs in a single night," as it takes weeks to pass through the various stages of transformation. The probability is that the wasps mentioned were of the species Vespa norwegica, and when taken at this season of the year, or a fortnight earlier, the workers naturally become inactive, although still inside the nest, as I have frequently noticed. The extra warmth and the disturbance of the nest by bringing into a dwelling would induce activity.

About a fortnight ago I cut one of these species of nest out of a Hawthorn bush for a farmer, and as it was a very good specimen it was intended to be placed in a glass case as an ornament. Before doing so I took the precaution to place the nest in a tolerably hot oven all night, in order to kill all the wasps inside, and dry any larvæ which might still exist in the combs. I also have an excellent specimen nest I cut out of a Holly-tree while the wasps were in full vigour in working. My method of procedure is to first drive inside any wasps building or protecting the nest by syringing with cold water, as a shower, gently, and then very carefully release the nest from all sprays except the main bough by which, it is suspended, with pruning scissors, and hold the main branch firmly, to prevent falling when cutting off.—J. HIAM, Astwood Bank.

ANTI-BLIGHT POWDERS.

What I may be doing is of very little consequence to anybody I surmise, but before my experimental Potato plots, whereon I have applied the anti-blight powders this year, arrive at their sere and yellow leaves, I feel that I should like you to see specimens representing the present appearance of their foliage. No. I represents leaves upon which I have applied a new powder that Messrs. Tate & Buchanan describe as "Agricultural" anti-blight, distinctive from their "Horticultural" powder, which has been three years in distribution. The Agricultural is a much cheaper production, and more palpably lasting upon the foliage, as you may observe. We have had severe winds and heavy rains since I applied it, the (with the fear of Mr. Abbey before my eyes as I write it) Phytophthora infestans spores would find it a great difficulty to enter the stomata through the above cuticle protective. Mr. Barron and Mr. Barr well know that I do not care a brass farthing about the under sides of the leaves, though I would not answer for the disease spreading if it gained a bed before the application.

I begin my dressings with the powder from the youth up of the haulm, at least, that is to say, I have done so with the "Horticultural" anti. The early frost came last year just as Mr. Barr sent me a supply and effectually put a stop to my powderings, so I have been using that reserve this season till I obtained the new "Agricultural" as I would presumably have done gold dust. Nos. 2 and 3 foliage have been dressed entirely with the "Horticultural" compound which do not maintain itself so distinctly upon any foliage, but the beautiful glaze and greenery it evolves makes it far preferable for greenhouse work, and with me it is quite effective in preventing the Potato disease. No mildew or vermin can ever become established on the haulm when dressed judiciously with powder. I send you also a first main leaf from one of my Tomato plants, which have now eight ripe and fourteen unripe fruit upon it. In practice I foreshorten the principal leaves to prevent crowding as the plants grow with single stems about 15 inches apart and 4 to 5 feet high, they are now a beautiful sight; we have Tomatoes galore, and between ourselves fried bacon and Tomatoes do not make a bad dish.

In passing Major Thoyt's lodge gate the other evening, I said to the occupant, "Good evening Pullen, how are the taties?" "Bad, bad." "Why you don't mean to say they are diseased?" "Just look across the garden there, they are gone quite black." Sure enough they were, and I see in another neighbour's garden next to me, he has cut off all his tops. Now if my neighbour's Potatoes are so diseased why should mine be left for four consecutive years? I will say no more, let those speak who have not borne the burthen and heat of the day.

As to fruit, my Gladstone and Irish Peach Apples were failures, plenty of Keswick Codlins, and my Pay the Rents and Wellingtons would break themselves down if they were not propped. Pears are good with me, or rather were, but the wasps necessitated my gathering them before they were ripe. Perry is the consequence, and cider will soon prove so with the Apples in part, and I regret to say so with Cox's Orange Pippin, of which I have a full crop. Of small fruits the missus's jam shelves are full, and so are my winc barrels. I never had a more bountiful supply of small fruits, but then, you know, I tapped one of the finest and unfailing springs when I first came here; and as Beau Brummel was said to say "Cravats made the man," I say water made my fruit.—ROBERT FENN.

[The specimens were withered when examined. We hear, however, of a projected pilgrimage to Sulhamstead, when the plants can be examined, and the overflowing stores of the veteran and his "missus" somewhat diminished.

NATIONAL ROSE SOCIETY.

It is with fear and trembling that I take up my pen to reply to Mr. Grahame, for it appears that in taking any notice whatever of his semi-official-looking circular we Secretaries committed, at all events in his opinion, a great blunder. For this unpardonable offence he tells us we "must take the consequences of the subject being discussed in the gardening Press." I suppose it is useless pleading that even such a fearful crime as simply trying to amend Mr. Grahame's circular cannot justly warrant so dreadful an exposure as that with which the Committee is now threatened. However, the deed is done, and the consequences must be faced as best they may.

In such straits one is apt to catch at any straw which happens to float by at the time. I am, therefore, wondering whether there is any slight consolation to be found in the thought that there is probably not a single society in the kingdom the management of which would altogether please so exacting a critic as Mr. Grahame. Again, but I suppose I must be wrong, I have hitherto been under the foolish impression that there is scarcely any other horticultural society which possesses so spotless a record of the past, or whose affairs would bear as searching an examination as our beloved National Rose Society.—E. M., Berkhamsted.

Notes About Roses.

I FEAR that I must have been misunderstood in what I said about Ernest Metz. I never meant to imply that it was not a most beautiful Rose when caught, but I did doubt its constancy upon this ground that special prizes have been offered for it at the Crystal the last three years, that in 1891 and 1892 there was no competition, and that this year, which was considered to be an especially favourable one for it, only the two great Colchester firms competed, and yet I know that several amateurs went in largely for it, and intended to compete, but could not. Perhaps another season may prove more favourable.

I note that your correspondent, Mr. Williamson, (page 170) expatiated on the satisfaction that Tea Roses had given him; he singles out a few by name, but curiously enough, three of them are not Teas. L'Ideal is a Noisette, as he will see it marked in the Rose Society's catalogue, while Gustave Regis and Cheshunt Hybrid are only Hybrid Teas. The latter have been long placed among the Hybrid Perpetuals, but is now transferred to the special class of Hybrid Teas.

A correspondent in one of your contemporaries made the statement that Louis Van Houtte was a sport from Charles Lefebvre. This was so new to me, and seemed so little credible, that I ventured to ask on what authority it was based. To this, as far as I can see, no reply has been given. Are any of your readers able to say whether they have heard this statement or not?

Whatever may have been the disappointment experienced by rosarians this year, they have had some compensation in the wealth of autumn bloom, not only in the Teas but in the Hybrid Perpetuals; the former especially have been a marvel of beauty.

While writing on the subject of Roses I would mention a matter on which I feel a little sore. I have just received from the Treasurer of the N.R.S. a list of those members who have not paid their subscriptions; this, I am sorry to say, amounts to ninety-five, or about one-sixth of the whole, and amongst these are to be found members of our Committee and many of our exhibitors. As a special circular was addressed to our members to ask them not to give this additional trouble, and that the plan of deducting their subscriptions from their prize money would not be allowed, I think, to say the least, it is very inconsiderate, and should this meet the eye of any of those alluded to I hope they will make no delay in sending in their subscriptions either to the Treasurer or to one of the Secretaries.—D., Deal.

CONTINUATION SCHOOL GARDENS.

A NOTE relating to the discovery of recently established school gardens in Lincolnshire having gone the rounds of the Press under the heading of a "Novel Idea," the following letter on the subject appeared in a recent issue of "The Standard."

"In reference to the 'novel idea' of boys' gardens in connection with schools, as announced in "The Standard" of the 14th inst., as well as in other journals, may I, as 'Horticultural Instructor,' acting under the directions of the Technical Education Committee of the Surrey County Council, briefly describe what is being done in the county mantioned in teaching practical gardening to youths in several villages?

"Small gardens in close connection with schools, it may be said, is by no means a novel idea. I remember, many years ago, observing plots of ground attached to the schools at Rangemore, supported by Lord Burton, and quite recently I have had the opportunity of inspecting school gardens at Hale, near Farnham, where plots of ground have long been provided both for boys and girls, the former for the cultivation of vegetables, the latter for flowers. These gardens have been established for about twelve years, and Mr. E. Cæsar, the schoolmaster, who is a

successful amateur gardener, has had pleasure in teaching those of his pupils who desired to learn what they could of gardening to cultivate these plots. They have always been in great demand, and most of them

have been very well managed indeed.

"Recognising the value of teaching practical horticulture in connection with schools, the Surrey County Council first provided a series of lectures on gardening for schoolmasters and pupil teachers; then plots of ground were obtained in villages to be worked by the older boys attending school, as well as others who have ceased attending, and who are engaged in various occupations in the parishes. The first of these small gardens—twenty-four—were formed at Banstead, on land kindly provided by Mr. Robertson Rodger, C.C. The plots of 1 rod each have been worked by the boys for two seasons, under the superintendence of local gardeners. Vegetables of approved varieties are grown, also a few flowers by those who desire to have them, while a plot of 4 rods is set apart for affording lessons in the cultivation of hardy fruits. These miniature vegetable gardens have been admirably cropped and cultivated. They are at this moment full of useful produce, and are neat, clean, and

They are at this moment full of useful produce, and are neat, clean, and orderly—cherished by the tillers and their parents alike.

"Similar groups of gardens are established at Ashtead, Fetcham, Hersham, Effingham, Clandon, Bookham, Horley, and Hale. It is my duty to inspect these plots periodically, give instructions, take note of the different crops and estimate their merits, which are represented in points, those boys who win the most by their diligence and aptitude being the recipients of prizes proportionate with the merit displayed. The Hale County Council Gardens have been quite recently examined, and it would be extremely difficult to find a weed in sixteen out of eighteen of them, while the crops are as good as could be expected eighteen of them, while the crops are as good as could be expected during the season of drought on an extremely porous and gravelly soil. These plots are, in fact, as well cared for, as clean, and as creditable as are any gentlemen's gardens in the district, and they have been admired by many visitors. It is not suggested that they excel the groups in other villages still to be inspected, and where the crops ought to be, and no doubt are, better, in the better soil. They are mentioned as showing that the best has been done that could be done under the circumstances, while a previously barren square of land has been rendered distinctly useful, the boys in the meantime gaining knowledge which can scarcely fail to be of service to them in after life.

"Each boy in the different villages is provided with a set of tools are intable size comprising a grade digging fook draw here. Dutch here

of suitable size, comprising a spade, digging fork, draw hoe, Dutch hoe, and planting fork or trowel, with sheds for their accommodation. These tools are inspected, and, with trifling exceptions, are kept in the most admirable condition, being made bright, and then lightly oiled to prevent rusting. Potatoes and seeds were provided for cropping, and prizes have been awarded for the produce at some local exhibitions. The boys attend horticultural lectures when these are given in their villages during winter evenings, and appear in every way anxious to acquire information on the management of land and the production of crops. So far as is known, the Surrey system of Continuation School Gardens is the most complete that has been yet established under County Council auspices; and it is hoped and expected that the rising generation will be benefited by the privileges afforded.—J. WRIGHT."

LILIUM LANCIFOLIUM AND ITS VARIETIES.

THERE are few more beautiful flowering plants for greenhouse or conservatory decoration at this season than the various types of Lilium lancifolium. Some few years ago they were cultivated more extensively than at present, and it is strange that such charming plants

should be neglected.

Good sound imported bulbs can be procured from any nurseryman. The bulbs will be found in most instances to be of a moderate size, and three are sufficient for a 10-inch pot. Drain the pots well, and place over the crocks a handful of partly decayed leaves, afterwards half fill the pots with a compost of fibry loam, one part dried horse droppings and rough leaf mould, adding a remaining part of broken red sandstone and coarse silver sand. This has been the best compost we have ever used, the growth of the plants being strong, and the flowers exceptionally fine. When the pots have been filled to the height mentioned give a sprinkling of coarse sand, on which place the bulbs, and fill up almost level with the top of the latter.

After potting we place the pots in a cold frame, plunging them to rims in ashes. If the soil was fairly moist no water will be the rims in ashes. requisite until growth is perceivable. Protection from severe frost may be afforded by covering the lights with any stout material, removing it on every favourable occasion, and giving ventilation when necessary. In this position they may remain until growth is well advanced in the In this position they may remain until growth is well advanced in the spring. The plants can then be removed outside, standing them on ashes, which will allow the water to drain away freely and keep out worms. As the pots become full of roots top-dress with a similar compost to that recommended. During growth, and until the buds begin to show colour, weak applications of liquid manure will be found very effectual. Soot is invaluable, the growth assuming a deeper green, and a sprinkling of some fertiliser is also beneficial. Neatly painted stakes should be placed to the growths to prevent the bulbs getting loosened, and when the buds show signs of colour a cool greenhouse is the best place, as then the flowers open perfectly clean.

the best place, as then the flowers open perfectly clean.

After flowering we never place the pots out of doors but in the greenhouse, and repot the plants when they have finished flowering. They are then carefully watered, for I am of the opinion that more failures occur through the pots being placed outside and exposed to the

cold rains of the autumn than from any other cause. As the stems show gradual signs of decay water is entirely withheld, and the pots transferred to a cold frame, where the bulbs keep plump and are ready to make a good start in the spring. The varieties we used to grow largely were Roseum and Album, but these are now superseded by Rubrum, with more intense colouring, and Album Kratzæri, with better formed flowers and a green band in the petals. I enclose a few flowers, from which you will see that our treatment is not very far wrong. -R. P. R.

The flowers sent are very fine, and reflect credit on the grower.

PROPORTIONAL PRIZES.

IF Mr. A Dean has been contending for the right of proportional prizegiving in the *Journal* (page 155) I am very sorry to have missed noting his efforts to effect this very just alteration. The Carshalton Exhibition appears to show the unfairness and absurdity of the ordinary method of prizegiving. Wherever I have had anything to do with schedule framing I have tried to bring the value of the prizes offered as near together as possible. When competition is severe there is often the slightest margin between the successful exhibitors, yet that slight difference may mean pounds, as for instance when the prizes are £15, £10, £5, and many of us can recollect cases in which the first prize has been £15, and the second only £5.

The large first prizes have arisen, as I believe, from a mistaken notion on the part of committees, that a good sum of money was a greater inducement to exhibitors to enter specimens. I do not know whether I am right or wrong, but I have always fancied that a larger number of exhibitors is obtained by a greater number of prizes. For instance, I think £10, £8, £6, £4, would bring together more competitors than £20 and £10, and if entry fees are charged this is a matter of some

moment to the Committee.

There are other advantages attending proportional prizegiving. It would necessitate greater care on the part of the judges, and though I believe in the great desire of judges to act fairly towards all exhibitors, everything that tends to the exercise of care and caution in awarding prizes is an advantage to the general body of exhibitors. Moreover, when there is a great difference in the value of prizes, exhibitors who, perhaps, naturally look favourably on their own productions, would probably acquiesce in the judgment when they saw how close was the competition, and everything that tends to kindly feeling between the two classes is an advantage. The office of judge, if honestly carried out, is no sinecure; it means a fair share of labour, and this method of prize-awarding would mean that every class would have to be "pointed." This is often quite unnecessary, one exhibit being often immeasurably superior to the other. No doubt a large number of judges would be required, and a stricter clearing of the tents at the stated time, a matter that is not sufficiently attended to at most shows, and one that greatly curtails the time at disposal of the judges.

I see some difficulties. Of course, instead of a certain number of prizes being offered, some such note as this would be necessary, "In the following classes such a sum (whatever the Committee have agreed to) will be offered in —— prizes." But what will a single exhibitor receive, or exhibitors, fewer than the number of prizes offered? Then it would seem necessary to have in the Secretary's tent someone well up in the matter of per-centages, whose duty it would be to thus divide the sum. I do not exactly envy him the work, and certainly the post will not be solicited by myself, although I suspect that these difficulties would soon be smoothed over.—Y. B. A. Z.

PRESENT USE OF HOTBEDS.

DURING such bright weather, such as we have had lately, it seems somewhat out of place to write about hotbeds and their uses; but a well constructed hotbed at the present time is of much importance for rooting the cuttings of various summer bedding plants which are required for stock for the following season. Some gardeners keep a stock in pots all the summer, which is a very wise plan. Where this is not done no time should be lost in striking a good batch of each sort used, and a hotbed is the most suitable place wherein to root the cuttings quickly. Such as Coleus Verschaffelti, Iresines Lindeni and Herbsti, Gnaphalium, Alyssum, Lemon-scented Verbena, Heliotrope, and Harrison's Musk, are easily rooted in a hotbed. Pelargoniums are the best rooted in boxes outdoors, Mesembryanthemums in pots in a cool frame or greenhouse, and rootlets of Lobelias dibbled in boxes and placed under a north wall till established. Alternantheras are generally taken up, divided, and put in boxes; but I like to have a stock of young plants also. They grow more freely during the winter and early spring months, and give a greater number of cuttings in the spring, healthier and freer in growth than those taken from old stock plants.

The hotbed should be made of litter, old dry leaves, and a little lawn grass mixed in, each layer being slightly damped as the work proceeds if the material is at all dry. About 6 or 8 inches of ashes, cocoa fibre, or sawdust, may be placed on the top when the material has been made firm. This is in the case of hotbeds made in deep pits; if they are to stand alone in the open the frame must be placed on at a certain stage, and more heating material added afterwards, so that the surface of the pots when plunged will be about 8 inches from the glass.

A suitable compost to root the cuttings in is half leaf mould and half loam, with a free admixture of sharp sand. Make the soil firm

in the pots before inserting the cuttings, and sprinkle a little sand upon the surface of the soil after the cuttings are in and watered. This helps to prevent damping. Be careful that the cuttings do not flag much before being placed in the frame, leaving a little air on at the top so as the vapour may escape. Attention is necessary afterwards to see that the cuttings do not flag, and are well shaded from all sunshine till rooted. When this has taken place air may be gradually admitted more freely, and the plants put in pots or boxes as is most admitted more freely, and the plants put in pots or boxes as is most convenient. If they be kept in a suitable temperature during the winter, and not over-watered, grand plants will be at hand for quickly increasing the stock to the required number.—G. GARNER.

HORTICULTURAL SHOWS.

SHREWSBURY.—AUGUST 23RD.

ONCE again has the famed and beautiful Quarry Grounds of historic and picturesque Shrewsbury been seen in a manner to be remembered. The best specimen plants that Britain can boast, with beautiful groups half filling one of the huge marquees; cut flowers in extraordinary numbers and superior quality, with floral arrangements of the first order of merit, and in some respects unique; fruit in enormous quantity and superb condition—the premier display of the year; vegetables as if grown for an army of giants; the best music the kingdom affords—the bands of the Royal Horse Guards and the Grenadiers, led by the "two Godfreys," with sundry other attractions of a very miscellaneous order; with Pain's fireworks and 40,000 people on the green sward, encircled by towering Limes, we have an aggregate of a very remarkable character brought together on the occasion of the "Floral and Musical Fôte"—the nineteenth of the series—the greatest and the best that has yet been provided by the Shropshire Horticultural Society.

The Society, as represented by the records of its shows, appears to have started well, and to have gone on improving with no checks worth mentioning, until it has reached its present commanding position in the horticultural world. The total receipts from the first Show in 1875 was £790, an amount it may be noted only a little above the sum allocated for prizes during the present year. The receipts last year from all sources were £3740. This year they may be a little less in consequence of the unfortunate disturbance in the coal trade, and thousands of men "out" of the class which, with their families, attend the great Provincial Festival. The takings on the first day (£535) were greater than on the corresponding day in any other year, while those on the record day amounted to £1400—a wonderful result under the circumstances. There was no falling off in the competition; but on the contrary, an increase of 200 entries, bringing the total up to 2400. This speaks well for the confidence that is reposed in the Society. Exhibitors are treated in no niggardly fashion, but every encouragement that can rightly be given is extended, as is instanced by the number of medals and special prizes granted for miscellaneous exhibits of a meritorious character. In a word a generous policy is pursued, and it is this which has mainly made the Society what it is. Societies that work on the principle of getting as much from and giving as little as possible to those who are in a position to support them, seldom if ever win a high position and gain the confidence of the horticultural community. Of such magnitude was this last Show at Shawkhury that no loss than twenty two Indoor was this last Show at Shrewsbury that no less than twenty-two Judges were engaged, and they could only just complete their duties in time for the public admittance. The following were the adjudicators in the different sections :-

SPECIMEN PLANTS AND GROUPS. — Mr. Outram, B. S. Williams and Co., London; Mr. Ranger, R. Ker & Sons, Aigburth Nurseries, Liverpool; Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley.

CUT FLOWERS, FLORAL DESIGNS, BOUQUETS, &C.—Mr. W. Dean, Sparkhill, Birmingham; Mr. Wright, Journal of Horticulture Office, London; Mr. Blair, gardener to the Duke of Sutherland, Trentham; Mr. Barnes, gardener to the Duke of Westminster, Eaton Hall.

FRUIT.—Mr. O. Thomas, gardener to H.M. The Queen, Windsor; Mr. Coleman, gardener to Lady H. Somerset, Eastnor Castle, Ledbury; Mr. Millon gardener to the Farl of Crower Combo Abbay: Mr. Rabone.

Mr. Miller, gardener to the Earl of Craven, Combe Abbey; Mr. Rabone, gardener to the Earl of Shrewsbury, Alton Towers.

VEGETABLES.—Mr. Muir, gardener to Miss Talbot, Margam Park, Glamorgan; Mr. Lambert, gardener to the Earl of Powis, Powis Castle, Welshpool; Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury; Mr. N. Pownall, gardener to F. Wright, Esq., Lenton Hall, Nottingham.

WILD FLOWERS.—Mr. W. Beacall and Mr. T. P. Blunt, Shrewsbury;

and Rev. W. Serjeantson, Acton Burnell.

COTTAGERS.—Mr. J. Jones, gardener to A. P. Heywood-Lonsdale, Esq., Cloverley; Mr. J. Wallis, gardener to R. Sneyd, Esq., Keele Hall; Mr. T. B. Field, gardener to Sir H. Thyrwhitt, Bart., Stanley Hall; and Mr. Farrant, gardener to Mrs. Juson, Shrewsbury.

Only the chief features of the Show can be noted, and the prizewinners in some of the principal classes recorded.

GROUPS AND SPECIMEN PLANTS.

Groups.—The schedule opened with a class for a "group of miscellaneous plants, in and out of bloom, arranged to produce the best effect, and occupying a space of 300 square feet." The prizes offered in these classes were £20, £16, £14, and £12 respectively, and it may be said that the winners of the third and fourth prizes were as well entitled to the amounts allocated as were the first and second prizewinners to the relative greater

sums. Five groups were arranged in squares and produced an imposing and diversified effect. After long and close examination the premier prize was awarded to the group of J. H. Manners Sutton, Esq., Kelham Hall, as arranged by Mr. A. Webb, gardener. It may be described as strong and rich, though perhaps a trifle heavy, yet it could scarcely be described as overcrowded, though undoubtedly, to use the familiar term of gardeners, there was "stuff enough in it." It was, however, good "stuff," the plants being bright and healthy. The arrangement consisted of a bold central mound of Crotons, Dracænas, and Ferns, surmounted with a spreading Palm. There were five or six smaller mounds of a similar character supporting isolated plants of Crotons, Dracænas, and small Palms in excellent condition. The ground, or dells between the elevations, was furnished with small brightly coloured plants and Ferns, not packed closely together, but dotted in the moss, and plenty of space between them. The background consisted of Palms, Crotons, and Liliums. The contour and character of every plant was displayed, instead of, as is so often the case, one spoiling the effect of the other by crushing and crowding.

That great prizewinner at shows, Mr. Cypher of Cheltenham, who has also the reputation that so many persons appreciate, of being a "good loser," just lost the first prize in this class but well won the second, an extremely light and chaste arrangement, but not, as some thought, quite rich enough. White as represented by Francoas and Caladium argyrites predominated under a canopy of Ferns. The plants were thinly disposed, and in that respect, perhaps, excelled all others, and the effect of the whole would have been enhanced with fewer variegated plants as a background. Mr. F. Denning, Birmingham, was placed third with a good but rather heavy arrangement, though lightened with a group of Tuberoses springing from a mass of Asparagus plumosus or allied form—an attractive combination. This is the best group we have seen from this exhibitor, who seems to possess the spirit of perseverance that usually brings success sooner or later. The remaining prize was worthily adjudged to the group of C. H. Wright, Esq., Halston Hall (Mr. Roberts, gardener), and was composed of bold masses of Liliums associated with Palms, interspersed with small Crotons and other plants—effective and ran its rival rather closely. The fifth group was arranged by Messrs. Jones & Son, Shrewsbury. Its merit was recognised by an extra prize of £5, and the exhibitors will now perhaps fortify themselves for another contest.

Specimen Plants.—The class for sixteen stove and greenhouse plants, half to be in bloom, created a good deal of interest, as it seemed to be understood that Messrs. Cypher and Finch (Mr. Marriott's able gardener) were showing their best for the premier (£20) prize. Some persons thought that the latter's magnificent Ixoras and brilliant Crotons would "pull him through," but the predominating view was that "Cypher would overweight him," and so it was. He won with a grand collection. His Ericas Eweriana, Marnockiana, and Aitoniana, also Allamanda Hendersoni, Dipladenia amabilis, Statice profusa, and Clerodendron were highly effective, and admirably supported by magnificent 8 feet Crotons angustifolius, Sunset, and Queen Victoria, and these well backed by lofty Palms—a ponderous contribution, as it had to be to hold the position against the Coventry contingent. Mr. Finch's Ixora Duffi was remarkable by the richness of its massive heads. Its equal has probably never been seen, and the Williams' Memorial medal was awarded for it as the best flowering stove plant in the Show. Finch had other fine Ixoras, a splendid Erica, fine Allamanda, good Lapageria, and glowing Crotons Prince of Wales and Warreni, but his Palms lacked weight. He well won the £15 prize, and £2 extra with the Williams' medal. There were no other competitors, and luckily, perhaps, for the large tent was overcrowded with exhibits.

Amongst these the plants in the class for Shropshire gardeners contributed effectively to the display. The first prize for six specimens was won by Mr. Pearson, gardener to Lord Berwick, Attingham Hall, with two Ixoras, an Allamanda, Dipladenia, Palm, and Croton, all in good condition, as were the plants with which Mr. Farrant, gardener to Mrs. Juson, Shrewsbury, won the second prize. Ferns were admirably represented, and the specimens of Salopian gardeners were most creditable, those of Mr. Penson, gardener to Lord Forester, Willey Park, Broseley, perhaps especially so. His plants comprised Microlepia hirta cristata, Nephrolepis davallioides, Polystichum capense, Adiantum decorum, Davallia Mooreana, and Adiantum farleyense, wonderfully fresh and healthy. Messrs. Bremmell and Steventon were also successful exhibitors. Tuberous Begonias, Fuchsias, Coleuses, Dracænas, and Caladiums were effectively shown by Messrs. Lambert, Leith, Bremmell, and other gardeners; but Orchids could not be expected to be numerous so late in the season. Messrs. Cypher and Shuttleworth & Co. (Bradford) were successful in the nurserymen's class, winning the prizes of £12 and £8 respectively, A. E. W. Darby, Esq. (Mr. Dawes, gardener), The prizes for being the only exhibitor in the amateurs' section.

Palms were won by Messrs. Cypher, Finch, and Webb.

In the same plant tent Messrs. T. S. Ware, Tottenham, had a splendid collection of Tuberous Begonias, for which a gold medal was awarded, a similar mark of distinction being granted to a most extensive and varied exhibit of plants by Messrs. Pritchard & Sons, Shrewsbury, and a silver medal to the Liverpool Horticultural Company for a fine group of Tea Roses.

CUT FLOWERS.

The cut flower section is always a heavy one. There were thirty-six classes in the division open to all. In the class for a collection of cut Roses, in space 12 feet by 6 feet, two admirable exhibits were staged, both from Scotland. Messrs. James Cocker & Son, Aberdeen, were well first with fine blooms, staged in small groups of separate varieties, a basket of Viscountess Folkestone being the centre object. Messrs. D. & W. Croll, Dundee, was second—a fine display, with a conspicuous centre of blooms of Maréchal Niel and Céline Forestier. For twenty-four cut Roses the prizes were awarded to these two firms, the

Aberdeen firm being first.

In the class for a collection of Dahlias of all types, in a space 15 feet by 6 feet, there was a display which drew forth warm admiration, Messrs. Keynes, Williams & Co., of Salisbury, easily taking the first prize with a fine assortment most effectively arranged; Mr. George Humphries, The Nurseries, Kingston Langley, second; Messrs. Jones and Sons, Shrewsbury, third; Messrs. Kimberley, of Coventry, also Messrs. Jones & Son, Shrewsbury, being commended. For twenty-four Dahlias—first, Mr. Humphries; second, Messrs. Harkness & Sons, Bedale; third, Messrs. Keynes & Co.

Three collections of Gladioli were staged, each in a space of 24 fect by 6 feet, and made a brilliant display. The first prize fell to Messrs. Harkness & Sons, Bedale, for bold, well-bloomed large spikes. Second, Messrs. Jones & Son, Shrewsbury. Third, Mr. Wm. Shaw, Kidderminster. For eighteen spikes of Gladioli Messrs. Harkness & Sons were first, and Mr. William Shaw second. Liberal prizes were offered for Begonia blooms in a space 8 feet by 6 feet, and here Mr. Davis of Yeovil had it all to himself with a very fine display. In the class for twelve bunches of stove and greenhouse flowers, Orchids excluded, some excellent exhibits were staged. Mr. Carling, gardener to Mrs. Cope, Woolton, Liverpool, was first, and other good boxes were staged.

A grand display was made with hardy border flowers, set up in competition for the liberal prizes for collections, each in a space 15 feet by 6 feet, annuals and shrubs excluded. Six collections were staged, and each deserved a first prize. Messrs. Cocker & Son, Aberdeen, were first with bold bunches in great variety, well arranged. Messrs. Harkness & Sons were second with a very extensive assortment, too much crowded into the given space. Third Messrs. Laxton Brothers, Bedford (succeeding to their late father's business), with noble bunches. Fourth Messrs. Biddles & Co., Loughborough. Fifth Messrs. Dicksons,

Chester, with an excellent group. Prizes of £5, £4, and £3 were offered for a collection of Carnations and Picotees in variety, shown with their own foliage and buds, and not dressed in any way, in a space 9 feet by 6 feet. The season for these flowers was over south of the Tweed, but three collections were staged from Scotland. First, Mr. Campbell, Blantyre. Second, Messrs. Laing and Mather, Kelso; and third, Mr. John Forbes, Hawick. It is an excellent idea, as it shows the character of the varieties, and had the month of August been the blooming time as usual with the Midland

growers, there would have been a much finer display.

Shrewsbury is famous for bouquets, and prizes of £5, £4, and £3 are annually offered for a ball and a bridal bouquet. Messrs. Jenkinson and Son, florists, Newcastle-under-Lyne, were first with two handsome shower bouquets. Second, Messrs. Perkins & Sons, Coventry. Third, Mr. Gilbert Davidson, Ammanford. Liberal prizes are also given for buttonhole bouquets, a hand bouquet, bridal bouquet, and epergnes. Another class is devoted to a decorative dinner table for ten persons with flowers and fruits. Messrs. Jones & Sons, Shrewsbury, were well first with two epergnes, and a good Melon, Pine, Nectarines, Peaches, and Grapes, and six small specimen glasses. Four other exhibits were staged in this class.

A new departure here was to be seen in liberal prizes being offered for a group of floral arrangements, in a space 12 feet by 6 feet. There were six competitors, all of considerable merit and beauty of arrangement. Messrs. Perkins & Sons, Coventry, were first with a splendid assortment, consisting of shower bouquets, in which shades of cream colour and light yellow predominated; others, made up of light coloured Cattleyas and Oncidium flexuosum; lovely baskets of flowers, anchors, wreaths, crosses, sprays, and along the top lovely fan-shaped arrangements of Grasses, Ferns, and foliage. Various other designs were staged in this collection, and in the centre was a large wedding cake ornamented with wreaths. Messrs. Jenkins & Sons, Newcastle, were a good second, and three equal third prizes were awarded. The amateur classes in the cut flower department were generally also well filled.

Fruit was magnificently shown, the competition in all the classes being very heavy, and with a remarkable absence of inferior exhibits. It was the largest and best exhibition ever held by the Society,

particularly of Grapes.

Collections.—There were five entries for twelve dishes of fruit, premier honours being secured by the Earl of Harrington, Elvaston Castle (gardener, Mr. J. H. Goodacre), who staged Muscat Hamburgh, very fine; Muscat of Alexandria, Madresfield Court, and Foster's Seedling Grapes, all in prime condition; his other dishes consisting of Walburton Admirable and Golden Eagle Peaches, Hero of Lockinge Melon, Brown Turkey Figs, Washington Plums, Victoria Nectarines, a good Pine, and a fine dish of Strawberries. Second, J. Corbett, Esq., Impney (gardener, Mr. Parker), with Golden Queen, Alicante, Alnwick Seedling, and Muscat of Alexandria Grapes, well finished; Cox's Orange Pippin Apples, Brown Turkey Figs, Humboldt Nectarines, Best of All Melon, Princess of Wales Peach, Jersey Gratioli Pears, Jefferson Plums, and a good Pine. Third, Hon. Mrs. Meynell Ingram (gardener, Mr. Dawes), a very close opponent, all the dishes being fine. Fourth, W. A. H. Marks, Esq. Ledbury (gardener, Mr. J. Bailey), who staged some very fine fruit, but his Pine was weak. For a collection of nine dishes of fruit, open to Salop only, the competition was keen. H. H.

Hayhurst, Esq. (gardener, Mr. S. Bremmell), secured first honours, his best dishes being fine Muscat of Alexandria and Alnwick Seedling Grapes, Bon Chrêtien Pears, Late Duke Cherries, Hero of Lockinge Melon, and Prince of Wales Peaches. Second, Rev. J. M. Buckley Owen (gardener, Mr. J. Langley). Third, J. Watson, Esq. (gardener, Mr.

A. Gant), both staging fine fruit.

Grapes.—The class for six bunches of black Grapes excited much attention, the prizes amounting to £19 causing heavy competition, and grand specimens were staged by many veterans. The Hon. C. H. Wynn, The Rhûg, Corwen (gardener, Mr. J. Bennett), was placed first with magnificent bunches of Gros Maroc, Alnwick Seedling, and Alicante, the size of berry, depth of bloom, and perfect finish were splendid. Second, the Earl of Harrington, with fine Gros Guillaume, Alicante, and Alnwick Seedling. Third, J. Grant Morris, Esq, Allerton Priory (gardener, Mr. Craven). Fourth, C. Bayer, Esq., Forest Hill, London gardener, Mr. J. Bury). Fifth, Earl of Cork, Frome (gardener, Mr. W. Iggulden). The two latter receiving extra prizes, their exhibits being so meritorious. For three bunches of Black Hamburghs, J. C. Sinclair, Esq., Rock Ferry (gardener, Mr. R. Brownbill), was first with beautiful examples in a heavy class. Second, J. T. Harris, Esq., Stone (gardener, Mr. J. Bates), with fine bunches, well finished. Third, R. Pilkington, Esq., Rainford Hall, St. Helens (gardener, Mr. G. Middleton). The class for three bunches of any other black was a grand one, many fine stands of Alicante and Gros Maroc having to stand out, as Madresfield Court swept the deck. Many exhibitors hope the Society will make a class for late Grapes another year. J. Grant Morris, Esq., was a good first with fine bunches, and berries well finished. Second, Mrs. Meakin, Cresswell Hall, Stafford (gardener, Mr. J. Wilks). Third, Hon. C. H. Wynn.

For four bunches of white Grapes in two varieties, J. R. Franklin, Esq., St. Hillary, Cowbridge (gardener, Mr. E. Silk), secured the first position with fine Muscat of Alexandria and Mrs. Pearson. Second, Hon. C. H. Wynn, with Muscat of Alexandria and Buckland Sweetwater. Third, Duke of Newcastle, Worksop (gardener, Mr. C. Slade), with Duke of Buccleuch, and Muscat of Alexandria. Many splendid lots could not receive notice as the class was so extensive. The white Muscat class was a big one, but though the fruit was fine in bunch and berry the colour generally was not good, and shrivelling had set in on many stands, the opinion being that the season has been too forcing to suit Muscats. R. Pilkington, Esq., was a good first. Second, the Duke of Newcastle, very close on the first. Third, J. Daintry, Esq., Congleton (gardener, Mr. A. H. Hall). For three bunches of any other white, J. Grant Morris, Esq., was first with fine well coloured clusters of Buckland Sweetwater. Second, Mrs. B. Darby, Baschurch (gardener, Mr. R. Lawley). Third, C. Bayer, Esq. Two bunches of Black Hamburgh Grapes, open to Salop only, first, Rev. J. M. B. Owen. Second, C. H. Wright, Esq., Halston Hall, Oswestry (gardener, Mr. C. Roberts). Third, G. Borr, Esq., Oaklands. Other successful exhibitors in the classes confined to Salop were Lord Harlech, Col. R. T. Lloyd, R. Darby, Esq., and Lord Berwick.

Lord Bagot, Blythefield, Mrs. Horsfall, and Mrs. Meekin were the successful exhibitors of Peaches, but the names of the varieties could not be ascertained; the fruit was very large and highly coloured. For Nectarines R. Sneyd, Esq.. Keele Hall (gardener, Mr. J. Wallis), was first with beautiful fruit of Darwin. Second, Lord Harlech, with Violette Hâtive. Third, Hon. Mrs. Meynell Ingram. Lord Harlech also took first with Apricots and with twelve purple Plums, J. Corbett, Esq., occupying a similar position with white Plums. Green-flesh Melons were well shown by Mr. J. Edmonds, Earl of Harrington, and Lord Berwick, who took the prizes in the order named. For scarlet-flesh Melons Rev. J. M. B. Owen, Hon. Mrs. Meynell Ingram, and the Duke of Newcastle took the honours as named.

Five splendid Pine Apples were staged by Mr. C. Slade, gardener to the Duke of Newcastle, well deserving the certificate of merit and special prize awarded. A similar prize was awarded to the Hon. C. H. Wynn for six Pine Apples, very fine. A special prize was awarded to C. Lee Campbell, Esq., Glewston Court, Ross (gardener, Mr. S. T. Wright), for three immense bunches of Black Alicante Grapes, which were also large in berry, with a dense bloom, in perfect condition. Mr. J. Watkins, Pomona Farm Nurseries, Hereford, was awarded a certificate of merit and a silver medal for a large collection of Apples, Pears, and Plums, all the fruit being large and of very high colour, attracting much attention: The English Fruit and Rose Company, King's Acre, Hereford, were awarded a certificate of merit for a large collection of Apples of brilliant colour for the time of the year.

VEGETABLES.

Large quantities of vegetables were shown, many of them of excellent quality, but better finished collections have been seen at previous Shrewsbury Shows. There were six competitors for the Society's prizes offered for twelve varieties, but the Judges experienced no great difficulty in awarding those prizes. Mr. T. Wilkins, gardener to Lady Theodore Guest, Blandford, was well first, having fine Autumn Giant Cauliflowers, Lyon Leeks, Sutton's Solid White Celery, Green Globe Artichokes, Exhibition Beet, Ne Plus Ultra Runner Beans, Satisfaction Potatoes, Perfection Tomatoes, Ailsa Craig Onions, Model Cucumbers, and Antegrat Ress. Mr. W. Bene gardener to the Forl of Cornervon. and Autocrat Peas. Mr. W. Pope, gardener to the Earl of Carnarvon, Newbury, took the second prize with a good even collection, in which Solid White Celery and Satisfaction Potatoes were particularly fine. The third prize went to Mr. R. Milner, gardener to Miss Talbot, Penrice Castle, Swansea. In the class for six varieties, this being confined to the county of Salop, there were twelve competing, a capital lot of produce

being shown. Mr. S. Wakeham, gardener to T. W. Williams, Esq., was first, he having good Autumn Giant Cauliflowers, Snowball Turnips, Ailsa Craig Onions, Intermediate Carrots, Main Crop Tomatoes, and Blood Red Beet. Mr. J. Abbott, gardener to Mrs. C. Guise, was a creditable second; and Mr. R. C. Townsend, gardener to Colonel R.

Lloyd, third.

Potatoes in all the classes provided for them were remarkably good, coarseness being less apparent, and less favoured by the Judges than usual. The best six varieties were shown by Mr. J. Hathaway, gardener to the Earl of Lathom, Ormskirk, who had Satisfaction, Edgcote Purple, Chancellor, Reading Ruby, Cole's Favourite, and Scarisbrick Favourite in perfect condition. Mr. G. H. C. Shorting was second, and Mr. E. Cumberbatch third. For three varieties, Mr. T. Griffiths, gardener to J. Dixon Taylor, Esq., was well first, having excellent dishes of The Bruce, Prizetaker, and Satisfaction. Mr. J. Hathaway was second, and Mr. W. Pope third. There were twenty-five competitors with one dish of Tomatoes, Mr. D. Sheppard, Winchcombe, being first with very good examples of Perfection; Mr. A. Ruddock being second, and Mr. W. Shaw third. Carrots, Turnips, Onions, and other vegetables in season were extensively and well shown, a whole tent being principally devoted to them.

Special prizes were offered by several of the leading seedsmen, the competition being good in most cases. Five competed with collections of vegetables, the prizes for which were provided by Messrs. Webb and Sons, Stourbridge. Mr. T. Wilkins took the lead with very fine Excelsior Onions, Webb's Solid White Celery, Autum Giant Cauliflowers, Autocrat Peas, Webb's Defiance Carrots, Sensation Tomatoes, Satisfaction Potatoes, and Ne Plus Ultra Runner Beans. Mr. C. Pope was second, his Mammoth Red Celery and Stourbridge Gem Cucumbers being extra good. The third prize went to Mr. J. Hathaway, the fourth to Mr. R. Milner, and the fifth to Mr. R. C. Townsend. Messrs. Webb & Sons also provided prizes for a dish of Tomatoes, and in this instance Mr. W. Loculden, gardener to the Earl of Cork. Frome, was first with well Iggulden, gardener to the Earl of Cork, Frome, was first with well selected Webb's Sensation; Mr. J. Langley, gardener to the Rev. Bulkeley Owen, West Felton, being a close second. Mr. J. Cooke, gardener to G. Singer, Esq., third, and Mr. J. Craven, gardener to J. Grant Morris, Esq., fourth. Messrs. Sutton & Sons offered prizes for collection of vegetables, the first of which only was open to all, the rest being confined to the county of Salon. Mr. T. Wilking was well first being confined to the county of Salop. Mr. T. Wilkins was well first with a collection very like that which he staged for the Society's prizes. with a collection very like that which he staged for the Society's prizes. Mr. S. Wakeham was a good second, Mr. R. Townsend third, Mr. G. Pearson, gardener to Lord Berwick, fourth, and Mr. J. Milner fifth. Messrs. Carter & Co., High Holborn, London, offered prizes in three separate classes, in each of which there was good competition, Messrs. Farrant, Iggulden, Bird, and others taking the prizes. Messrs. Taylor and Thomson, Bishopsgate, London, also provided good prizes for their customers to compete for. The first for a collection of vegetables was well won by Mr. W. Pope, Mr. T. Wilkins was second, and Mr. R. C. Townsend third. Townsend third.

The first of the prizes offered by the late Mr. Laxton for four varieties of his new Potatoes was won by Mr. W. Iggulden, who staged medium-sized tubers of Early Laxton, Reward, Victorious, and General. The winner of the first prize for Clibran's Tomato was Mr. A. Ruddock, gardener to E. A. Young, Esq., but the fruits were rough. A series of prizes were offered by Mr. R. Sydenham, Birmingham, which attracted fairly good competition. Messrs. G. Cooke, A. Lowe, Bridgend, and W. T. Roderick, gardener to A. M. Biddulph, Esq., Chirk Castle, being the principal prizewinners. The names of the winners of the prizes offered by Messrs. Thompson & Co. did not transpire in time for inclusion in this report. Cottagers' exhibits were extensive and meritorious.

HONORARY EXHIBITS.

These alone were sufficient to make up a very fine Exhibition. Gold medals were awarded to Messrs. Dobbie & Co., Rothesay, for an enormous collection of Dahlias, choice Sweet Peas, African and French Marigolds of the finest quality, summer Chrysanthemums, herbaceous and other flowers—a bright, varied, and admirably arranged display; also, as previously stated, to Messrs. Thomas Ware & Co., Tottenham, for a very fine collection of Begonias in pots and in a cut state, and to Messrs. Pritchard & Sons, Shrewsbury, for a very extensive bank of

decorative plants.

Silver medals were awarded to Mr. Albert Myers, nurseryman, Shrewsbury, for a bank of plants; Messrs. Birkenhead, Sale, for choice Ferns; Messrs. Dicksons (Limited), Chester, a collection of plants; Ferns; Messrs. Dicksons (Limited), Chester, a collection of plants; Messrs. Wm. Cutbush & Son, Lendon, collection of cut flowers; Messrs. Hewitt & Co., Birmingham, Begonias and other plants; Messrs. Phillips and Co., Shrewsbury, a collection of fruit; Mr. Watkins, Pomona Farm, Hereford, collection of Apples, Pears, and Crabs; The Liverpool Horticultural Society for a group of Roses in pots. The Williams' Memorial medals, and £2 to Mr. W. Finch, gardener to Mr. Alderman Marriott, Coventry, for his grand example of Ixora Duffi, and to Mr. W. Evans, Stone, Staffordshire, as an amateur who does not employ a gardener, for a fine plant of Oncidium incurvum. for a fine plant of Oncidium incurvum.

Certificates of merit were awarded to Messrs. Perkins & Sons, Coventry, for seedling Cactus Dahlias Grand Mogul and Matchless, also to a lovely Pompon, Greyfriars; Messrs. Keynes, Williams, & Co., Salisbury, for seedling Cactus Dahlias, Gloriosa, Dawn, and Mephistopheles; Mr. Hy. Eckford, Wem, for Sweet Peas; Mr. Wm. Innes, Rothesay, for Pansies and cut flowers; Messrs. Edwards & Sons, Sherwood Nottingham for floral decembers. Messrs. Lowers for Co. Chard. wood, Nottingham, for floral decorations; Messrs. Jarman & Co., Chard, for a collection of vegetables; Mr. W. D. Bacon, Wolverhampton, for new Milltrack Mushroom spawn; The English Fruit Company, Hereford,

for a collection of Apples and Pears; Laxton Brothers, Bedford, for Sweet Pea Princess May, in colour very like Countess of Radnor.

A special silver medal was awarded to Mr. Wilkins, gardener to Lady

Theodore Guest, for twelve sorts of Onions, six bulbs of each, very large and well ripened, a wonderful exhibit, Ailsa Craig standing out prominent amongst them.

Such is the general character of the Shrewsbury Show. Only by great zeal, sound knowledge, and unremitting labour on the part of the Committee and experienced Secretaries (Messrs. Adnitt and Naunton) could such gigantic displays of garden produce be arranged. The success of the Society has been phenomenal, and the town, its charities, schools, and other objects have shared in its prosperity to the amount of £3500. Bravo, Shrewsbury!

TROWBRIDGE .- AUGUST 23RD.

THE forty-fourth Exhibition of this Society was held on the above date under favourable circumstances, and must have proved a financial as well as a horticultural success, judging from the immense number of visitors and the extensive array of exhibits on view. No large money prizes are offered to attract exhibitors from a distance, but the district is one from which a first class exhibition may be made. Fuchsias are always a feature here, and it is doubtful whether a rival exhibition of these popular plants could be found anywhere. The redoubtable Fuchsia raiser, Mr. James Lye. gardener to the Hon. Mrs. Hay, Market Lavington, was the champion in both classes provided—namely, for four and six plants, his specimens being perfect in every detail, and standing from 8 to 10 feet in height. Mr. Geo. Tucker won the second, and Mr. Pocock, gardener to J. P. Haden, Esq., third prize.

For nine stove and greenhouse flowering plants, Mr. Mathews, gardener to Sir W. Roger Brown, was first, but Major Clark followed him very closely, Mr. E. B. Rodway being third. This was a strong class, including good, healthy, well-trained and perfectly flowered plants of Allamanda nobilis, A. Hendersoni, Bougainvillea glabra, Lapagerias rosea and alba, Ixoras, Ericas, Eucharis amazonica, Rondeletia speciosa, Clerodendron Balfourianum and others. The same exhibitors secured the prizes in the order given for six and three flowering plants. For fifteen Ferns or Mosses Mr. G. Tucker was a good first, Mr. Haden second, and Mr. Sancombe third. Sir Roger Brown Mr. F. Applegate and Captain Spicer (gardener Mr. F. Perry). Brown, Mr. F. Applegate, and Captain Spicer (gardener, Mr. F. Perry), shared the prizes for foliage plants in the order named. Only two exhibits of Caladiums were staged, but these were large, well grown plants of good variety, Mr. Pocock was first and Mr. Mathews second. Mr. Mathews was again to the front in a strong class for specimen trained Coleus, the Hon. Mrs. Hay second, and Mr. E. B. Rodway third. Mr. Mathews was the only exhibitor of Heaths, six plants, and gained the first prize. Mr. Pymm, gardener to Mrs. Goldsmith, was first for a group of plants arranged for effect on a space not exceeding 50 square feet, but Mr. Deacon, gardener to H. Harris, Esq., Calne, staged a much more effective arrangement, highly coloured Crotons, Eulalias, Dracenas, Hedychiums, and Orchids, being raised lightly from a groundwork of Ferns, Panicums, and similarly dwarf plants. Mr. Pymn's was a simple "bank," too symmetrically arranged, and devoid of the undulating features that characterised his opponent's exhibit. Mr. Tucker was first for six well grown Gloxinias, also for the same number of Achimenes and double Begonias. Mr. Keen won with six single Begonias, with profusely flowered plants of small blooming sorts, quite out of date according to present day's standard of perfection. The premier award for Orchids was won by Mr. Pymm, Sir Roger Brown being second, and Mr. Deacon third.

Cut flowers were well represented, Asters being first-rate. Messrs. W. J. Jones, G. Garaway, Bath, and A. A. Walters, Bath, won the prizes with twenty-four German Asters; while with French of the same number of blooms Messrs. A. A. Walters, T. Every, and G. Garaway were the winners in the order of their names. Roses were not extensively shown, but for the season were very good indeed. In the open classes Dr. Budd, Bath, was first for twelve bunches; Messrs. Cooling and Son second; and Mr. W. Smith, Kingswood, third, and these positions were repeated by the same growers for twenty-four Roses, single blooms. In the amateurs' division Dr. Budd was beaten by Mr. T. Hobbs, Bristol, in the class for twelve bunches, and also for twelve single blooms. Gladiolus, Verbenas, Hollyhocks, hardy annuals, and choice greenhouse cut flowers; Dahlias, and trusses of brightly coloured Zonal Pelargoniums were each represented in large numbers of good stands.

In the fruit tent it was universally admitted that the Show was one that had never been equalled on any previous occasion, every class being largely contested. For a collection of ten dishes, excluding Pines, Mr. W. Strugnell, gardener to W. H. Long, Esq., M.P., Rood Ashton, Trowbridge, first, his dishes being Black Hamburgh, Muscat of Alexandria and Alnwick Seedling Grapes, Blenheim Orange Melon, Bellegarde Peaches, Pineapple and Stanwick Elruge Nectarines, Jefferson Plums, Brown Turkey Figs, and Morello Cherrics placed on brightly coloured leaves of Ampelopsis Veitchi. Mr. G. Pymm was second with good Foster's Scedling and large bunches of Black Hamburgh Grapes, Exquisite Peaches, Green Gage Plums, Lady Sudeley Apples, Cherries and Pears. Mrs. Hardwick, Bradford-on-Avon, and Mr. W. Goele gordener to Maior Handwick Campton Passet Ware a Ware deepend Cook, gardener to Major Heneage, Compton Basset, were awarded equal thirds, and there were two other collections. For a collection of six varieties Mr. F. Parry was successful over Mr. Palmer, Bradford-on-Avon, and R. B. Cater, Esq., Bath. Grapes were numerous in the

several classes provided, but particularly so in the one for black, in which Muscats are excluded. Mr. W. Marsh, Coombe Down, Bath, was first with large, shapely bunches of Alicante, perfect in colour and berry. Mr. T. Jones, Bath, second for Gros Maroc. Third, Mr. Attwell, Stoke Bishop, Bristol. Messrs. J. Dole, J. Gibson and Attwell won with Buckland Sweetwater in the class for any other white, and for White Muscats Messrs. T. Jones, J. Gibson and Attwell were again the successful competitors. Black Muscats were the least strongly contested, Messrs. Jones, Gibson and R. J. Philips, gardener to Mrs. John Baily, Frome, sharing the prizes in the order named. Mr. E. D. Foxcroft, Bath, and Mr. J. Stratton, Melksham, won with green-fleshed Melons, Mr. S. Humphrey and Mr. J. Gibson with scarlet-fleshed sorts. Mr. W. Strugnell won with dessert Plums, Mr. Pymm with Cherries, Mr. J. Colman, Bristol, Peaches, Mr. Strugnell Nectarines, Mr. G. Garaway dessert Apples, and Mr. Strugnell culinary Apples, showing Peasgood's Nonesuch, weighing from 16 ozs. to 22 ozs. each.

Bouquets, wreaths, and vases of flowers were a good feature, and as usual attracted much attention. Messrs. Attwell, A. H. Newman, and E. T. Hill of Bristol; Brown & Son, Frome; W. Strugnell, and Miss Maud Cole were the principal exhibitors; the memorial wreath of the

latter being particularly good.

Vegetables, as is always the case at Trowbridge, were staged in considerable quantities and in the highest state of excellence, this applying equally to the open, amateurs', and cottagers' sections. Messrs. Webb and Sons, Stourbridge, offer prizes for a collection of six sorts, and this, as well as the open to all class, were both won by Mr. Geo. Garaway, market gardener of Bath. Potatoes were numerous and good, so also were Carrots and Onions; but Peas and Beans displayed evident signs of the ungenial weather experienced of late.

of the ungenial weather experienced of late.

Mr. James Huntley has been Honorary Secretary for upwards of thirty years, and his genial manners and business capacities win him many friends and helpers. Both Secretary and Committee work hard in the promotion of, and the carrying out the arduous duties involved in such an exhibition, and they deserve all the praise bestowed. The prize money is always paid before exhibitors leave the field, and the Society, it may be added, is in the most flourishing state, with a

substantial reserve fund in hand.

BASINGSTOKE.—AUGUST 25TH.

The annual summer Exhibition of this Society was held in Hackwood Park—a charming site for such a fête. With the exception of a few showers in the morning the day was delightfully fine, many persons taking the opportunity to visit the Show, the park, and the military tournament. The Exhibition was decidedly good, and superior to any previously held under the auspices of the Society. The competition was keen in nearly all classes, while the quality of the exhibits left little to be desired. Vegetables were admirably represented, a few perhaps too large, and it was evident the Judges paid more regard to high quality than mere size. The arrangements were under the superintendence of the Hon. Secretary (Mr. J. A. Wallington) and his efficient assistant (Mr. Weeks), and left little to be desired. Four marquees were necessary to accommodate the exhibits, and so well were they arranged that ample space was provided for the visitors to inspect the Show without unpleasant crowding.

Plants were not only numerously staged, but of good quality. The principal class was for twelve specimens, in or out of bloom. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, was easily first, so good were his plants of Allamanda grandiflora, Clerodendron Baifourianum, Statice profusa, and Ixoras in the flowering section, combined with several well coloured Crotons and healthy Palms. Mr. T. Russell, gardener to W. Bradshaw, Esq., Audley's Wood, was second by the superiority of his flowering plants. Mr. H. Brown, gardener to A. B. Welch-Thornton, Esq., Beaurepaire Park, third. Mr. Russell was the first prizewinner with six plants in flower, staging good specimens. Mr. T. Weaver, gardener to W. C. Gilchrist, Esq., Oakley Park, Basingstoke, secured first honours for six foliage plants, healthy well-developed Palms with fairly good Crotons being conspicuous. Mr. Brown second, Mr. Russell third. For a collection of miscellaneous plants arranged in a semicircle, effect to be the leading feature, there were three exhibitors, Mr. Bowerman and Mr. Weaver making a grand display for the first and second prizes in the order named. The only fault that could be found with the first prize group was a slight preponderance of Crotons and Tuberoses. The group was well arranged, light and effective. Mr. Weaver erred by crowding the plants, which were good, but too numerous for the purpose. Mr. G. Southcott, gardener to Captain Oldfield, Basingstoke, third. In the class for single specimen flowering plants Mr. Bowerman secured the premieraward with Allamanda Hendersoni, Mr. Brown coming second with a well-grown plant of Clerodendron fallax. These two exhibitors reversed the order in the specimen foliage plant class, Mr. Brown having Cycas revoluta, while Mr. Bowerman had a well coloured Croton Queen Victoria. made a great display. For twelve plants Mr. H. Brown won easily with handsome specimens, carrying remarkably good blooms. Mr. G. Best, gardener to F. W. Leyland, Esq., The Vyne, Basingstoke, was second. Mr. Brown also won with six plants. Coleus were remarkably well shown. For four pyramids Mr. G. Southcott was distinctly ahead of Mr. T. Russell; the plants from both were over 6 feet high and well Mr. Brown staged the best Liliums, well grown and flowered plants of the lancifolium type. Mr. Weaver had best six exotic Ferns, well developed examples of popular kinds. Table plants were numerously staged, Mr. Best winning for twelve, Mr. Bowerman being an extremely close second. Many other plants were well represented,

space only preventing our naming the winners.

Cut flowers added greatly to the attractiveness of the Show. Roses were not numerous, but the prize flowers were of excellent quality and well arranged. For twenty-four blooms Mr. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester, was the only competitor, but he staged remarkably handsome blooms. He also well won premier honours with twelve blooms. Mr. Russell was second. For twelve bunches of cit flowers Mr. G. Best won the first position with a neatly arranged collection. Hardy herbaceous flowers were staged in quantity, Mr. N. Kneller, gardener to W. S. Portal, Esq., Malshanger Park, was first, and Mr. Best second. Mr. Weaver won with twelve trusses Zonal Pelargoniums, Mr. Kneller second, both staging well. Dahlias were fairly well represented, Mr. R. H. Munday first, Mr. Neville second. The first-named had the best Asters in twelve blooms, a really good stand, mainly of the Comet type. Table decorations, bouquets, and sprays were well represented in classes open to ladies only, Mrs. Whitlock, Mrs. Thorne, and Miss Owen being the most successful exhibitors.

Fruit made a capital display. For eight dishes Mr. Bowerman was an easy first, staging nicely finished bunches of Gros Maroc and Muscat of Alexandria Grapes, Barrington Peaches, Countess Melon, Brown Turkey Figs, and Williams' Bon Chrêtien Pears. Mr. T. Osman, gardener to L. Baker, Esq., Ottershaw Park, Chertsey, was second, he also staging well. For a collection of six dishes Mr. Osman was first, Mr. H. Brown second. Grapes were well represented. In the Black Hamburgh class Mr. Bowerman was first with medium sized bunches, having good berries and colour, Mr. Brown second. In the any other black class Mr. Osman was first with Alicante, admirably coloured, Mr. Bowerman and Mr. Kneller following in the order named. Mr. Brown had the best White Muscat Grapes, staging fairly good examples, Mr. Osman second, though he took the highest position in the class for any other white with Foster's Seedling. Mr. Russell had the best green flesh Melon, a tolerably good one of Hero of Lockinge; Mr. W. A. Hunt second. A somewhat peculiar circumstance occurred in the scarlet flesh class, Messrs. Wright and Molyneux withholding all the prizes, so unpleasant, not to say nauseous, were the fruits. Mr. Bowerman had the best Peaches, Sea Eagle, and Mrs. Field the best Nectarines. Apples made a great display. For three dishes of dessert kinds Mr. Kneller was placed first, Mr. Nevile second. Kitchen varieties were well represented also, as were Plums, Mr. Bowerman winning for three dishes.

Vegetables filled the whole of one side of a large tent. For six varieties, the prizes offered by Messrs. Sutton & Sons, Mr. Lye, gardener to W. H. Kingsmill, Esq., Sydmonton Court, Newbury, beat his formidable opponents, Messrs. Kneller and Bowerman, who were placed in the order named. In the first prize collection were grand examples of Satisfaction Potato, Perfection Tomato, Excelsior Onion, Sulham Pink Celery, Mammoth Cauliflower, and New Intermediate Carrot. Mr. Bowerman turned the tables on Mr. Lye in the class for the best collection in competition for Messrs. Carter's prizes with a good collection, consisting of Rousham Park Onion, Autumn Giant Cauliflower, and Satisfaction Potato. Messrs. Bowerman and Lye won first and second prizes offered by Messrs. Webb for six varieties with produce similar to the foregoing in quality and variety. Mr. Lye won the first prize offered by Messrs. John Sharpe & Son, Mr. Best second, and Mr. Bowerman third, all staging excellent produce. For a collection of Potatoes in nine distinct varieties Mr. Lye was an easy winner with clean shapely examples of leading varieties.

Messrs. Sutton & Sons, Reading, had a collection of cut blooms of annuals and perennials, with several plants in pots of their choice Begonias, Shrimp Pink and Queen of the Whites, all bearing a deep

impress of the strain sent out by this firm.

HARDY FRUIT GARDEN.

Cleansing Fruit Rooms.—As the time is fast approaching when fruit rooms will be fully occupied, it is desirable that everything should be clean before bringing in choice Apples and Pears. Wholesome conditions in the storing of fruit are imperative. Taints of any kind, musty smells, and an unsuitable atmosphere will soon be transferred to the delicate flesh of Apples and Pears. Therefore let the walls be whitewashed, the shelves and woodwork thoroughly cleansed with soap and water, and the floor scrubbed, admitting plenty of air afterwards to dry the structure quickly.

Gathering Apples and Pears.—No wholesale clearance of the fruit from trees must yet be adopted where it is necessary to store specimens for future use, but where Apples and Pears for immediate supplies are needed, especially for cooking purposes, any sufficiently sized fruit may be secured. Fallen fruit collected and used at once proves useful, but such ought not to be stored in the same place with choice carefully gathered specimens. Varieties which ripen immediately may be picked as soon as they part readily from the spurs. To remain

on the trees until dead ripe has the effect of the fruit losing its freshness, aroma, and flavour if stored. If gathered just on the turn, without injury, and kept in a cool dark place with the atmosphere pure and sweet, neither too dry nor damp, each specimen will finish well

Hints on Storing Fruit.—Place Apples and Pears in the store-room in single layers on clean dry boards or shelves, from which they can absorb no taint or smell. Avoid laying fruit on straw of any kind, as the least mustiness in it will be attracted to the fruit. Clean white paper may be employed with advantage to cover shelves. With varnished white wood shelves fitted in the fruit room there is little fear of fruit being injuriously affected. Common deal boards often contain turpentine. Plums to be kept for future use should be allowed to hang until perfectly ripe, then carefully gathered with the stalks intact, wrapped in tissue paper, and laid in a dry airy place in the fruit room. It is the late varieties which are chiefly stored to yield a succession as long as possible, but some weeks may elapse before it is needful to detach the fruit from the trees where it is desirable they should hang protected, in the case of very choice varieties, with gauze bags from the attacks of birds, wasps, and bluebottle flies.

Protecting Choice Fruit.—Specimens of any kind of soft fruit intended for any special purpose should be effectually secured against the attacks of birds and insects. The former may be kept at bay by the judicious use of nets, but for the latter other contrivances are necessary. The gauze bags referred to are the surest means of protection, while bottles of sweetened beer hung about the trees will attract and drown numbers of wasps and flies. Earwigs are often prevalent, soon doing much mischief. The only way of guarding against their depredations is to trap them in short lengths of bean stalks, examining the traps every morning, and blowing out the insects into hot water. Keep the surroundings of the trees clean, as earwigs, woodlice, and other marauders always accumulate among weeds and rubbish, especially if dry and partly decayed.

Supporting Fruit Trees .- As trees are relieved of their crops some assistance may be necessary to aid the roots in perfecting the fruit buds for another season. Adequate moisture in the soil in which the principal fibrous roots ramify is the first essential. Red spider increases fast when the soil is deficient in this respect, and the leaves once overrun with this small, but troublesome pest their premature loss is certain, to the detriment of the fruit buds which derive their main support from healthy green foliage fully exposed to light and air. Further assistance being needed after the soil is properly moistened it may be afforded by applications of liquid manure. Weakly trees only should be treated to this. It will cause their buds to plump up better, and the growth generally to be strengthened. Trees already strong enough had better not be encouraged to make further growth. It may be advisable to restrict the rooting powers of such trees if fruitless, and this condition grises from excessive growth.

Thinning out Crowded Branches.—This is the best period of the year for such operations. There is no advantage in having the interior of trees full of wood and foliage which cannot receive any light. Every superfluous branch is detrimental to fruitfulness. While the foliage is present on the trees a better idea can be formed of the exact distances branches require in order to fully receive and benefit by the full admission of sunshine and air to every leaf and bud.

Subduing American Blight.—This is now very conspicuous on many Apple trees, and an attempt ought to be made to arrest its increase. Spirits of turpentine and petroleum are both effectual destroyers of the pest without injury to the trees if used judiciously. The application must not be heavy, only sufficient to moisten the bristles of a paint-brush, then dabbing the insects and their fluffy covering with either spirits of turpentine or petroleum. The oil must not be allowed to run to waste down the stem, or saturate the bark. A portion of the loose downy substance can be collected on a saturated brush without touching the bark or stems at all to any extent.

FRUIT FORCING.

Vines in Pots for Early Forcing .- Those intended for starting early in November should now be completely at rest, the wood thoroughly ripe, the laterals cut close back, and the canes shortened to about 6 feet-more or less, according to the length required for the position they are to occupy and the situation of the plump eyes. If the Vines are kept rather dry at the roots it reduces the tendency to bleeding, or the cuts when dry may be dressed with styptic or knotting. Do not allow the soil to become dust dry, for this causes the roots to shrivel, whilst a very wet condition may induce the decay of the fibres. Keep the Vines in a cool, airy house. Later Vines in pots may be placed outdoors to harden the growth and induce rest, the south side of a wall or fence being preferable. If Vines have to be bought they should now be ordered. The best for early forcing in pots are White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court.

Earliest House.—The earliest forced Vines—those started from early December to January—should now be pruned. It is not necessary to wait until all the leaves have fallen if the Vines are going to rest—the wood brown and hard and the leaves turning yellow; the pruning will cause the Vines to rest more quickly and thoroughly. loose bark should be removed, washing the rods with clear rain water and afterwards with an insecticide or a solution of softsoap, 4 ozs. to a gallon of water. If there be any scale or mealy bug add half a wineglassful of petroleum and half an ounce of washing soda to the solution, and keep it well mixed whilst being applied with a brush to reach every hole, angle, and crevice. Before dressing the Vines the woodwork

should have been cleansed with softsoap and water, the glass with clear water, and the walls limewashed. Top-dress the borders both inside and outside, clearing away the old mulching material and the loose surface soil first; then supply fresh turfy loam, with a 9-inch potful of bonemeal and double that quantity of wood ashes to every 3 bushels of loam, and make firm. Weakly Vines, or those in an unsatisfactory state, will be improved by removing the soil down to the roots and supplying fresh turfy loam with an admixture of a sixth of old mortar rubbish and a sprinkling of bonemeal and wood ashes, lifting any roots available for the purpose, and laying them out in fresh material within 6 inches of the surface. This, however, is best done before the leaves have fallen. Comparative dryness is desirable, but excessive drought weakens, if not destroys, the young roots, and a sodden soil causes their Outside borders should have a covering of some kind to protect them from the heavy autumn rains, which reduce the temperature considerably. Glass lights are much the best, as they throw off the rain whilst allowing the sun to warm the soil. These not being available, and they need only be used in the case of heavy rains, a covering of leaves and litter will be necessary after the weather sets in cold. 1

Late Grapes.—Continue a night temperature of 65° and 70° to 75° by day artificially, with 80° to 85° from sun, until the Grapes are perfectly ripe, ventilating freely and keeping lateral growths closely stopped a warm atmosphere with a few lateral growths closely stopped, a warm atmosphere with a free circulation of air being essential to thorough ripening. Laterals allowed to grow only excite root action, and this encourages late growth. Material for covering the borders should be held in readiness, for late Grapes keep much better when the roots are not chilled by the autumn rains. Tarpaulin, shutters, or roots are not chilled by the autumn rains. Tarpaulin, sthatched hurdles can be used for this purpose when required.

Young Vines.—These generally make a strong growth, and are consequently late in ripening. Such should be assisted with fire heat, maintaining a minimum temperature of 65° and a maximum of 75° from fire heat, running up to 85° to 90° from sun heat, accompanying the artificial heat with a little top and bottom ventilation so as to insure a circulation, increasing it proportionately with the sun heat. Laterals also should be kept well in hand, not, however, pinching them so close as to start the principal buds.

Cucumbers.—Earlier closing and syringing is necessitated by the shorter and colder days, it being desirable to husband the sun heat and have the foliage fairly dry before dusk. Employ fire heat to maintain a temperature of 70° to 75° by day and to secure 65° at night. Keep the shoots thin, remove old growths to make room for young ones, and so insure a succession of bearing wood. Stop young shoots a joint beyond the fruit. Encourage root action by a steady bottom heat of 80°, surface dressings of lumpy loam and sweetened horse droppings, and afford tepid liquid manure whenever water is required. Do not allow the fruit to hang after it becomes fit for use, and avoid overcropping.

Autumn-fruiting Plants.—Stop the growths so as to insure an even spread of bearing wood. Remove the staminate blossoms and tendrils, also the first fruits. No shading will now be necessary. Cease syringing the plants in the morning, and only practise it lightly on bright afternoons, keeping the house damped as occasion requires. Admit air early but moderately, avoiding draughts, for chills stunt the growths, and a confined atmosphere causes the foliage to become thin and flabby. Endeavour to secure a sturdy growth whilst opportunity offers by early

and judicious ventilation.

Winter-fruiting Plants.—The plants from seed sown early in August are now fit to place in their fruiting quarters. The house must be a light one, have a south aspect, and means of securing a temperature of 65° to 70° in all weathers. A bottom heat of 80° to 90° is also necessary. All soil previously used must be cleared out, and the whole of the interior of the house scalded, if possible, with hot water, washing the woodwork with softsoap, water, and a brush, making the glass clean, and lime-washing the walls. Where rubble is used over and about the pipes for bottom heat see that it is clean; if not, take it out and cleanse it by washing. Secure the drainage with a layer of turves, slightly charred, grass side downwards. Place in hillocks or ridges of soil of about 2 feet base, 10 or 12 inches depth, and 1 foot across at top. Use turfy loam of medium texture two-thirds, fibrous sandy peat one-third, rejecting any woody matter, old mortar rubbish freed of laths or pieces of wood, with the rough broken small one-sixth, and nut charcoal one-twelfth, the whole well incorporated. This material is equally suitable for plants in beds, pots, or boxes, and should be made moderately firm. Pots or boxes must be well drained, and only so far fille i with soil that when the plants are introduced their seed leaves will be about level with the rims of the pots, and as they will have some stem below the seed leaves which will admit of earthing as the plants increase in growth. Very serviceable fruits can be had from plants in pots or boxes in houses with a stove temperature, training the growths so that their leaves will be clear of the Plant when the soil is warmed through, press it gently, and secure the plants to stakes reaching to the trellis. Rub off the laterals to that height, and stop the leading shoot at about the second or third wire of the trellis. Shade from bright sun until established. Syringe lightly in the early afternoon, damp the house in the morning, noon, and afternoon. Maintain a day temperature of 70° to 75°, rising 10° to 15° from sun heat, and a night temperature of 70°, falling 5° through the night. The plants will give fruit in the late autumn, but they must not be cropped much if they are to produce a crop from Christmas to spring.

Seed may now be sown for raising plants to give a supply of fruit about Christmas and onwards. Telegraph is still one of the best varieties. Place the seed singly in 3-inch pots a little more than half

filled with soil, and cover half an inch deep. A pane of glass over each pot will bring up the plants quickly; remove it as soon as they appear above the soil, and keep well up to the glass. Earth up the plants as they require it, and transfer to 5-inch pots when they need a shift, placing a stick to each, to which secure the plant as it grows. Rub off laterals as they show, and train with a single shoot. The plants will be fit to place out during the first fortnight of October

fit to place out during the first fortnight of October.

Pits and Frames.—The growths in these will need to be kept thin as a safeguard against damp, and watering must be done early and with care and judgment, as cold and damp are disastrous to Cucumbers late in the season. The plants will need very little water after this, as the roots get enough moisture through the decay of the fermenting materials. They must not, however, be allowed to flag, and a light sprinkling may be given occasionally at closing time. Line the beds with stable litter, and admit a little air at the back to allow of any steam escaping. The temperature should be kept at about 65° at night, employing a covering of mats over the lights on cold nights. With due attention to the linings and covering Cucumbers will be obtained from these structures for some weeks to come.

Strawberries in Pots.—Any plants not yet in their fruiting pots should be given them without delay. Placed in 5 or 6-inch pots, according to the size of the plants, they will fill them with roots before the winter, and though not so large as those potted earlier, will give some fine fruit, if they are not started before February. Plants potted some time ago should be examined, and if making side buds these ought to be removed with a pointed piece of hard wood, so as to throw the vigour into the central crown or bud. Vigorous plants will not require liquid manure, but weakly ones may be supplied with it twice a week. All runners must be removed as they appear, also weeds. If the surface of the soil becomes hard loosen it, especially at the sides of the pots, so as to ensure the thorough moistening of the ball. As the plants grow set the pots farther apart so as to expose the foliage to light.

APIARIAN NOTES.

BEES AT THE MOORS.

WE have now at the time of writing reached August 28th, and the morning dawned the pleasantest I have witnessed since I came on the moors. Ice was as thick as a shilling, and every green thing stiff and white as at midwinter. The rain four days previous to the 26th completely washed the honey out of and spoiled some Heather, but there still remains a great quantity of it in fair order, but all is past lower down the hills. The long continuation of the bloom here gives us bee-keepers an advantage over those where it is warmer and the Heather naturally earlier but shorter in duration.

Owing to the prolonged spell of stormy weather during the best of the Heather bloom the yield of honey is not so great as it might have been, but on the whole is fairly good; and now with the improved weather at the end more may be added. It is rather singular to witness honey gathering, swarming, and frosty weather at same time, but experience gives confidence, and is more reliable and valuable than theory.

From one hive there has been an increase of eleven, while other four have been frustrated, making sixteen in all had they been allowed. As my time is limited, further particulars I will hold over till later on, when I will give them in a concise form for the benefit of beginners; and, I may add, for modern bee-keepers in general.—A LANARKSHIRE BEE-KEEPER.

PREPARING FOR WINTER.

Those who already possess stocks must, unless the bees are taken to the moors, at once begin to prepare for winter; each stock must be fed up to a sufficient weight, and if need be strengthened by an addition of driven bees, in accordance with the instructions given in these columns, and then when every attention has been paid to these salient points the less the bees are disturbed until March next the better it will be for the stocks. If it is desired to ruin a stock late feeding and continued manipulation in the late autumn will soon do its deadly work; but if strong, prosperous colonies are desired that can be had with as little trouble and not much more expense than starveling stocks, which, dragging on a weary existence through the winter, are a discredit to any bee-keeper, and a sign of lamentable slothfulness and neglect.

Bees must be kept strong, and the fact can never be too often impressed upon bee-keepers in general, and some in particular, that one strong stock is of more value than three weak ones, and with less time expended on it in the way of manipulation will give greater results than the three weak ones put together. True, in exceptional cases a weak stock does in spring make a rapid advance, but this is only by way of exception owing to a young and vigorous queen; but even this rapid progress

is not in the same ratio as that which a strong stock, headed by an equally good queen, would make under the same circumstances.—F.

TRADE CATALOGUES RECEIVED.

Dobie & Dicks, 66, Deansgate, Manchester.—Dutch Bulbs.
James Douglas, Edenside, Great Bookham, Surrey.—Catalogue of Carnations, Picotees, and Auriculas.

C. Turner, Royal Nursery, Slough.—Hyacinths, Narcissus, Tulips, &c. R. Veitch & Son, High Street, Exeter.—Dutch Bulbs, &c.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

wasps (S. S.).—If you consult the last few issues of the Journal of Horticulture you will, we think, find recorded all the known remedies for destroying wasps; but after all that is done the plague continues, and each fruit grower must adopt the best local measures available for saving his fruit. There is no universal panacea, any more than there is for ridding the world of flies and various insect pests.

Glands on Peach Leaves (Ignoramus).—The glands are minute wart-like growths at the extreme base of the leaves, and in some instances are round and in others kidney shaped. In some varieties of Peaches and Nectarines the glands are visible enough, in others more or less obscure, while a few are glandless. Examine a number of leaves of different varieties closely, and your eye will soon become educated on the subject of glands.

Exhibiting Shallots (H. Bell).—You ask if the Shallot is a vegetable on the ground that "a friend was disqualified because he placed a dish consisting of one variety in a collection of vegetables." We have many times intimated that the schedules of shows should accompany questions of this nature, in order that we may see the precise conditions under which exhibits must be staged. Of course the Shallot is a vegetable, but all the same, may not be admissible in certain classes, according to special stipulations which, if ignored, might result in disqualification.

Grapes Shanking after Ripening (R. C. N.).—There is such a thing as Grapes shanking after they are ripe, both when they are hanging on the Vines whilst these are in leaf, and after the Grapes have been bottled and placed in the Grape room. One form of shanking is caused by a micrococcus, and produces an enlarged or ulcered condition of the footstalk prior to the shanking, and it is likely that shrinkage of the footstalk without the ulceration may be caused by the same micro-organism, but this is as yet undetermined, and in fact, no malignant bodies have been discovered in the wire-like shanked footstalks.

Nectarines Shrivelling (Cestria).—The shrinking generally occurs at the apex, and is rather common with the fruits borne by young or vigorous trees, and the fruit partakes more or less of the nature of the growth. When such fruits ripen the watery matter is dissipated, and as this is most abundant where the swelling has been greatest they shrivel. The shrinkage is generally confined to Nectarines, Peaches under the same conditions being little affected, as they retain more of the watery matter in ripening, and the evaporation takes place more evenly through their having downy skins. The fruits affected are not really a defect of culture. Perhaps a slight shade in very bright weather would have prevented the shrinking; but the best preventive is plenty of air, taking care not to over-feed the trees.

Clematis Failing (Tom Ridley).—We have examined all the sprays you forwarded, and have been unable to find any parasite likely to cause the appearance presented by No. 3 spray. No. 2 is, as you say, "beginning to go," but you have not sent that part where the mischief begins, and the collapse of the portion above the seat of the malady is only a question of a few days and sometimes hours. No. 1 is healthy; in fact, all the sprays are free from malignant micro-organisms, for, as before stated, the attacked parts have not been sent. This is sometimes situated on the stem and at the node or joint next the root on which the variety is grafted, then the plant collapses altogether, and often the same year as planted. But the attack is generally confined to the base of the annual growths where they spring from the preceding year's wood, and

it is not restricted to the first, but the secondary growths collapse in a similar manner. It is occasioned by a fungus or micrococci which girdles the shoot, and causes the collapse of the part above the affection. confined to certain species of Clematis, and is culturally believed to be due to over-propagation, but this is purely conjectural. The only thing we have found of any use is to promptly cut away the affected parts a joint or two below where they die off; but the disease is, in some cases, so fixed in the basal portion as to be beyond remedy, for to cut the affected parts away in some cases means the destruction of the plants. It is best to limit yourself to those varieties which succeed the best in the position assigned to them.

Truffles (R. B.).—The lump of soil sent contains what resembles Truffles, but in such a state of putrefaction that it is impossible to speak with certainty on the subject. The common Truffle (Tuber estivum), as described by Thompson in the "Gardeners's Assistant," "is nearly spherical in shape, and has been known to attain a weight of 3 or 4 lbs., and measure 4 inches in diameter. The surface is rough, warty, and black. The flesh is greyish, or white when young, black veined with white when old. The smell is powerful, but by no means unpleasant. It grows from 2 to 10 inches under the surface of the ground, and the spots where it is to be found are discovered by means of dogs trained for the purpose. It is abundant in some parts of Britain, particularly in Wiltshire, Kent, and Hampshire, but never occurs in any but calcareous toils, where it grows under the shade of trees, generally the Oak and Beech. In warm moist years it may be found throughout the year, but most abundantly from August to October." We reproduce a fine specimen

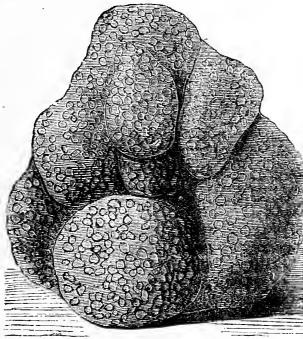

FIG. 30.—A BLACK TRUFFLE.

of the black Truffle. Just as many aërial fungi only grow on dead wood, and that of a particular kind, so the black Truffle is only met with among the roots of trees, and more especially the common and Evergreen Oak and Quercus coccifera. It is among the roots of these trees that the Truffles are most abundant, and acquire a perfume that makes them esteemed all over the world. Truffles increase like other allied fungi. When ripe they contain minute spores not exceeding 1.250th of an inch in diameter, and when the Truffle decays in the ground these produce white threads or mycelium, like Mushroom spawn when running, and

a fresh crop results.

Names of Fruits.—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. H. Eldridge).—The Apples are evidently seedlings, as we do not recognise them as among named sorts. No. 1 is not unlike as we do not recognise them as among named sorts. No. 1 is not unlike Irish Peach; Pears No. 2 quite rotten, and No. 1 resembles Verulam. (B. W.).—No. 1, Greenup's Pippin; 2, Fearn's Pippin; 3, small Scarlet Nonpareil; 4, Cellini. (F. John Gray).—1, Ribston Pippin; 2, Dutch Codlin, small; 3, not known; 4, Reinette de Caux; 5, Yorkshire Greening; 6, Emperor Alexander. (A. H. L.).—1, Wadhurst Pippin; 2, Lord Derby; 3, Beurré d'Amanlis; 4, Summer Rose; 5, Greenup's Pippin; 6, Lemon Pippin. (J. R. B. Watson).—1, Grosse Calebasse; 2, Beurré Superfin; 3, too unripe. (E. J. M.).—Undoubtedly Golden Queen. (W. P. S.).—Nouveau Poiteau. (D. M.).—The coloured Pear, which is quite ripe, is Beurré d'Amanlis, but we do not think the other is the same; Apples—No. 1, Greenup's Pippin; 2, Ribston Pippin; 3, decayed; same; Apples—No. 1, Greenup's Pippin; 2, Ribston Pippin; 3, decayed; 4, Gravenstein. (J. F. W.).—We cannot name Peaches without a portion of the young wood and information as to the size of the flowers; the one sent is evidently one of Mr. Rivers' seedlings, probably Early

Louise. (B. Wells).-5, Emperor Alexander. The others not worth naming or growing except for cider. (*E. H.*).—1, Norfolk Colman; 2, Striped Beefing; 3, Winter Hawthornden; 4, Greenup's Pippin. (*A. E.*).—1, Sandringham; 2, Blenheim Pippin; 3, Ecklinville; 5, Cox's Pomona; 6, Lord Derby (?). (*H. R. Dugmore*).—1, Napoleon; 2, Maréchal de Cour; 3, Grosse Calebasse; 4, Beurré d'Aremberg; 6, Winter Nelis. Six is the maximum number of collection and the better they are the better their chance of being named. (Thos. Pye).—Lane's Prince Albert (?); 2, Alfriston; 3, Winter Hawthornden; 4, Roundway Magnum Bonum. (A. J. N.).—1, Louise Bonne of Jersey; 2, Nouveau Poiteau; 3, General Toddleben; 4, Marie Louise; 5 and 6, Beurré Capiaumont. (J. S. B.).—1, Dredge's Fame; 3, Scarlet Nonpareil; 4, Court Pendû Plat; 5, Cox's Orange Pippin. Late truits should be contracted in the principle period. sent nearer the ripening period.

Names of Plants.—We only undertake to name species of plants,

not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (H. J. P.).—Oncidium microchilum. (H. F.).—Dendrobium canali-

THE DAIRY—FODDER CROPS.

Among dairy farmers having nothing but permanent pasture for the cows, there is much complaining of poverty of herbage, and a consequent lowness of milk yield. This, for the moment

is bad enough, but the outlook for the coming winter is still more gloomy. Where is the Michaelmas rent to come from? and how are the cows to be fed next winter? are questions to which no satisfactory answer appears forthcoming from that section of the farming community who, placing their dependance entirely upon pasture, have been content to take all they could get from it, without spending a penny upon manure of any sort, and with as little expenditure as possible upon labour. In ordinary seasons, with an average rainfall, this answers sufficiently to enable them to pay their rent, to obtain means for subsistence, and to "keep the money together;" or, in other words, to keep capital invested in the business intact. But the folly and risk of such a system, of such absurd parsimony, is only too apparent under stress of a drought, when the pasture fails them, and they have nothing else on the farm to turn to. Then the underfed cows quickly fall off in condition, there is a proportionate decrease in the milk yield, which, of course, tells upon the milk sold, or the butter and cheese made, as well as upon the quantity of such produce.

Of the cheese rooms we have inspected this season, the only one that is really satisfactory in both quantity and quality of cheese is that of a Midland tenant farmer, who not only systematically applies manure to his pasture, but also has enough arable land to afford a supply of other green crops, roots, and corn. He also employs sufficient labour to have all necessary work done well and quickly. In this matter his views are peculiar, aa he will only have young men and lads who board and lodge at the farmhouse, and who have to work with him. In a new farmhouse and homestead in course of construction for him we have taken care to have enough bedrooms for his requirements, so anxious are we to encourage good, sound, sensible practice on the estate. We have also given him special facilities and convenience in the outbuildings, but as all this will be explained in another article, we refrain from further mention

Our especial object here is to call attention to green crops, which have proved useful under the great drought, while pasture has failed so generally, but not universally. It is important to mention this, because though the valleys of the Trent, Wye, and Derwent in Derbyshire; of the Soar in Leicestershire, and many a rich alluvial "level," marsh, and fen, have had abundant herbage for grazing, and a full hay crop, we have also seen excellent pasture at hill farms where good management and thorough cultivation of the pasture prevails.

Of all auxiliary green crops none have told better this summer than green Maize. No doubt it was the spring drought that induced much more of it to be sown than usual, but still there is not half enough of it grown. Well does a correspondent in The Field ask why stock-owners do not try it more generally? He goes on to say, "There is a stupid prejudice that it is a tropical plant which is quite unsuitable to our English climate. But this is not true. If the farmer were advised to grow the grain it would be quite another matter, but at least in the southern half of England a large crop of green Maize is as certain as Turnips, more certain than Mangolds, and withal the simplest and cheapest crop to grow which can be mentioned. This is the seventh year the writer has taken a crop without a failure, although with one partial failure. Curiously, the great value of Maize is felt in years like the present, inasmuch when grass suffers for want of rain and great heat Maize flourishes best if it has firm hold of the soil. At almost all times in normal years the pastures are bare in autumn, just when Maize comes in; milk consequently falls off when it is most valuable on account of its superior quality. How opportune, then, comes the daily waggonload of Maize, which is strewn about the pastures and eaten up, stock, lock, and barrel, by the ravenous cattle, whose partiality for it is sufficient to convince the feeder of its value."

Sorghum saccharatum has been of equal value this year. Both crops grow with such freedom, yield so large a bulk of nutritious succulent food per acre, develop with such marvellous rapidity, and are alike useful as green food or for silage, that they should be regarded as indispensable. In so hot a summer Maize answers everywhere. We have seen recently Maize of a good height on the borders of Yorkshire. Both these grand forage plants are exceedingly nutritious. The Sorghum may perhaps be the more fattening of the two as it is so rich in saccharine. We have tasted excellent sugar made from plants grown in this country.

WORK ON THE HOME FARM.

The Early Drumhead Cabbages drilled in April bid fair to be ready for use before the green Maize is finished. This is what we particularly aim at—this overlapping of successional crops. Anything like the free growth of Cabbage or Kale this summer has only been possible where land was really well done. As the Rye folds were ploughed the drill followed at once day by day; there was thus plenty of moisture in the soil to make quick seed germination a certainty, and the land was so rich in fertility that plant growth was equally speedy. Trifolium incarnatum, the crimson flowered Italian Clover, has been got in well on a clean stubble, nicely softened by rain, so much so that only light Barley harrows were used. These were passed over the stubbles first, then the seed-28 lbs. to the acre-was sown broadcast, well worked in

by bush harrows, which were followed by a light roller.

A field of Sutton's Giant Evergreen Italian Rye Grass sown early in September proves most useful throughout the following year. Sow 3 bushels of seed per acre, and take care that it has rich land; it is then invaluable as green food in stables and cow-house, for hay, for silage, and for sheep-folds, a fold of "Italian" being generally regarded as equal to three folds on pasture, because it affords food for three times the number of sheep that the best pasture does. On poor land it is comparatively worthless, and the seed is wasted, for though it may germinate freely the plant comes yellow in bine, and its growth is so stunted as to be worthless. Under the high cultivation of which it is so worthy it continues growing freely from early spring till late in autumn, giving crop after crop of marvellous abundance, no fodder crop known to us being more useful. We place some stress upon this because of the popular idea that this grand crop requires a sewage farm. Unquestionably it, like green Maize, gives a much greater bulk of crop under the advantage of irrigation, but we need only to take care to sow on land rich in fertility to obtain heavy crops of both. We have long held it in high esteem for its earliness, coming into use as it does before mixed seeds or ordinary pasture.

OUR LETTER BOX.

Brewers' Grains for Cows (E. C. C. D.).—Brewers' grains should be used in moderation for cows when the milk is required for butter, of which they are liable to affect the flavour injuriously if used as a principal article of diet. They are considered to promote a full yield of milk and are used freely where milk is sold for immediate consumption. Stored in large quantities in a compact mass, grains keep sweet and wholesome for months, and we recommend the use of them with due caution for all cows while fodder is so scarce and the price of hay is so high.

REMARKS.

REMARKS.

20th.—Occasional sunshine in morning, shower at 3.30 P.M.; fair evening.

21st.—Cloudy, with frequent slight rain; sun in afternoon, fresh breeze; fine evening.

22nd.—Cloudy, with bright sun occasionally early and throughout day, fresh breeze; dark and heavy, with strong wind at 5 P.M.

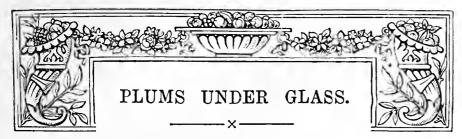

23rd.—Dull, with slight rain early, and rain at 9.20 A.M., dark at 11.15, and rain up to 3 P.M., then fair.

24th.—Overcast early, a little sun during morning with strong breeze, sunny rest of day; fine night.

25th.—Bright and sunny morning, a little cloud at 2.10 P.M.; sun bright at times in afternoon, but generally overcast; fine night.

afternoon, but generally overcast; fine night. 26th.—Bright and sunny throughout.

A fine week, and though nearly 10° colder than the previous one it has been above the average temperature.—G. J. SYMONS.

DLUMS generally are more impatient of a forcing atmosphere than any other stone fruit. This, however, does not preclude the successful cultivation of the choicer varieties under glass, for with properly constructed and well managed houses Plums of the highest excellence may be readily obtained. Lean-to structures erected against south-east, south, or south-west walls answer admirably, provided they are well ventilated, the border thoroughly drained, and adequate supplies of water given the trees. The side and top lights should open the whole length of the house, and the roof lights be moveable. Cases 6 feet in width will accommodate trees on walls and others on a low trellis in front, say to the extent of one-third the distance up the sloping roof. The front trees may be trained as cordons, and, duly restricted at the roots, they bear abundantly. This plan, however, is not so good as training half-standard trees to a trellis fixed 9 to 12 inches from the glass, the stems being the height of the front lights. Less space is afforded by this method, but the fruit attains to greater perfection and is more abundant than on trees trained to the wall. When the house is 10 feet or more in width, bush, pyramid, or low-stemmed trees with round heads may be grown with great advantage in front, either planted out or in tubs, and so arranged as not to deprive the trees on the back wall of too much light. Grand Plums are also grown in wall cases by planting the trees in front, one to each rafter, and training them up the roof as cordons. This does not prejudicially affect Peach or Nectarine trees on the wall.

Span-roofed houses with the ends north and south, or north-east and south-west, are suitable for standard Plum trees—the best of all methods of training stone fruits under glass. A row of trees can be disposed in the centre, and a row on each side of the house. It is imperative that the trees have stems so high that their heads will be exposed to full light. If grown in pots it matters little what form the trees are in, nor what height or width the house may be if it is light and airy. In exposed localities it has been recommended to sink the floor of the house somewhat below the surface, so as to secure the advantage of earth heat, and facilitate the covering of the roof with mats or canvas in severe weather. The great objection to sunk houses is damp, especially in low sites. With the trees in pots the roof lights may be fixed, as they can be transferred anywhere at will, and the grand secret of success in the culture of Plums in cool houses is keeping the trees dormant as late as possible, with the soil in a thoroughly moist condition. Excessive dryness at the roots as a means of forcing the trees to become and remain dormant till late in the spring often causes the buds to fall. When the trees are fully exposed from the fall of the leaves to the bursting of the buds inactivity and the soundness of the buds are assured during the resting season, and Plum trees take no harm whatever in the severest weather when the pots are plunged over the rims in ashes. An orchard house with boarded sides, not so close as to entirely deprive the trees of light on frosty nights and on cold days when the house is shut, hinged boards at the sides opening the full length of the structure provide efficient ventilation, and the roof glazed with large panes of glass, is the exact position for growing Plum trees in pots. This site affords sufficient shelter against our uncertain springs, insures the perfect ripening of the fruit in cold, dull, wet seasons, and prevents its

deterioration by throwing off rains and keeping it safe from dews and fogs.

The early and late varieties are invariably excellent for growing under glass, but the crackling-fleshed and high quality midseason varieties, as the Gage race, Jefferson and Kirke's, do not always finish satisfactorily, the fruit turning soft and shrinking instead of ripening. The late Mr. T. Rivers advised trees of these Plums to be removed to a warm and sheltered situation outdoors for ripening; it is an excellent plan provided means are taken to protect the fruit from rain, otherwise it cracks in wet weather. This method can only be adopted with trees in pots. For planted-out trees careful attention is necessary in ventilating, watering, and feeding during the early stages of growth, with plenty of air moisture when the fruit is swelling, especially at night in dry hot summers. Air at the time of ripening cannot be too freely admitted, as it is excessive evaporation which causes the fruit to ripen prematurely and be soft and poor in flavour. Oullins Golden is very handsome and as good as it looks, but the tree grows too freely to fruit well, yet it frequently does better under glass than in the garden. Denniston's Superb admits no rival in its season for crop and quality. McLaughlin may be described as a large Green Gage with a fine perfume. Brahy's Green Gage is earlier than the old Green Gage and larger; it certainly is one of the most delicious Plums. Early Transparent Gage is excellent for growing as cordons and in pots, but the fruit requires to be somewhat severely thinned. Green Gage bears enormously when the soil is firm and the roots restricted or root-pruned. Transparent Gage grows vigorously, and it requires a firm soil and restriction at the roots or root-pruning. Purple Gage shrivels, and is richly flavoured accordingly. Lawson's Golden Gage affords a pleasing variety and is excellent in quality. Guthrie's Late Green and Reine Claude de Bavay, with Late Transparent Gage, continue the supply up to October, and collectively comprise a dozen of the richest Plums in cultivation. They are all, except Purple Gage, greenish yellow, or yellow streaked or blotched with green or purple. Bryanston Gage also ripens late in September, and the tree is very prolific. Few, if any, Plums are richer flavoured than Angelina Burdett, and being black with brown spots is of good appearance. Of other Plums for dessert Early Favourite ripens as soon as any, followed by De Montfort, Jefferson, Kirke's, Coe's Golden Drop, and Ickworth Impératrice, so that with a judicious selection choice fruit can be had from trees in a cool house from July to November inclusive. The following are also good for dessert or culinary when grown under glass-Czar, Belgian Purple, Sultan, Denbigh, Victoria, Italian Prune, Prince Englebert, Washington, Monarch, Imperial de Milan, Blue Impératrice, and Grand Duke. All may be grown as cordons, planting the trees about 2 feet apart, and training the stems about 1 foot from the glass. If the trees are fan-trained fewer varieties will be required. Denniston's Superb, Brahy's Green Gage, Jefferson, Transparent Gage, Kirke's, and Coe's Golden Drop cannot well be excelled for affording a succession of choice fruit.

Whether the trees are planted out or grown in pots they require a rather stiff soil. Good calcareous strong loam interspersed with small stones or flints needs no admixture for borders. Efficient drainage, consisting of 3-inch drains to carry off superfluous water, 1 foot depth of rubble, preferably brickbats with a 3-inch top layer of old mortar rubbish, and 18 to 24 inches depth of soil are necessary for borders. For pots or restricted borders a fourth part of well decayed manure to three of stiff maiden loam, with a 9-inch potful of bonemeal and a quart of soot added to every 3 bushels of compost, are suitable. If the soil is deficient of grit and lime add a fifth part of sifted old mortar rubbish, and if turfy use Thomas's phosphate instead of bone dust. The pots should be drained thoroughly with crocks or oyster shells. Make the soil firm and allow sufficient space for helding water. Planting or potting is best done immediately the leaves have fallen. Potted trees ought to be plunged

in ashes, and it is desirable to allow them to make a year's growth outdoors before they are placed under glass for fruiting. When trees two or three years from the bud or graft, and especially in pots, can be had, it is better to purchase such than to rear them, and being furnished with blossom buds a crop of fruit may be had the first year.

If the trees are placed outdoors each winter (after the fruit is gathered in the case of early varieties), they should be returned to the house before the buds are so far advanced as to show colour, allowing plenty of room for the development of the growth, and standing each pot on two or more bricks on the flat a little distance asunder, so that the roots will not pass into the soil, whilst insuring a free passage for the water. Such trees can be moved at any time without prejudice to the growth. When the trees are kept under glass constantly the ventilators should be wide open during the winter whenever the temperature is above freezing point, but when frost prevails they ought to be kept closed. The trees also should be placed close together, so that they can be protected from frost by a covering of dry hay or straw between and over the pots, standing them apart in the spring. Similar remarks apply to plantedout trees in respect of ventilation under fixed roofs in winter, but the better plan is to remove the roof lights when the leaves have fallen and keep them off until the spring.

Under the circumstances indicated the trees will start naturally in the spring, and from this time forward a circulation of air, except in severe weather, should always be maintained by leaving the ventilators open more or less day and night. Abundance of air and a dry atmosphere is the only way to secure a proper set of fruit. By the time the fruits are set and swelling the sun will have considerable power, and may be taken advantage of to accelerate the growth by reducing the ventilation in the afternoon, yet leaving some, airing early each morning, and when the wind is sharp and cold ventilate on that side opposite its direction. In the summer the ventilators should be kept constantly open.

The trees must never be distressed for lack of a supply of water; one flagging ruins the crop for the season, and trees in pots are successful in proportion to the watering and nourishment. The soil must always be kept moist. Trees in pots require water twice, sometimes three times a day in the summer; also top-dressings of rich compost, preferably pieces of turf, to encourage plenty of surface roots, which can be fed to any extent by liquid manure and sprinklings of chemical fertilizers occasionally. Trees in borders will require water less frequently, that depending on root area, the spread of the top and the crop, but there must not be any deficiency of moisture or want of food. Over-watering and over-feeding must not be indulged in, for the Plum is impatient of extremes, but liberal treatment should be accorded if the trees are expected to produce full crops annually. As the fruit advances in ripening lessen the supplies of water and withhold liquid manure, but the foliage must not be allowed to become limp or to flag.

From the time the fruit is set until it begins to ripen the trees should be syringed in the morning, also in the afternoon, except on dull cold days, when a genial atmosphere may be secured by damping the paths and borders when they become dry. Syringing the trees must cease when the fruit commences to ripen, and the atmospheric moisture be gradually reduced, but a little of the latter will not do any harm provided the air is not stagnant, and it is necessary for the perfecting of the fruit and the health of the foliage. Hexagon netting over the ventilators, and frame doors covered with it, are necessary to exclude bluebottle flies and wasps, otherwise use the thinnest muslin over the trees or enclose the fruits in bags of that material. After the fruit is removed recourse must be had to syringing, watering, and proper supplies of nourishment for the perfecting of the wood and buds for next year's crop. Early varieties in pots should be placed outdoors as soon as the fruit is gathered, assigning them a sunny position, and duly attended to in watering and syringing. Midseason varieties may be treated similarly, also the late sorts as they are cleared of fruit.

Repotting or top-dressing is best done before the leaves fall. The object to be kept in view is to secure fresh roots in new material, therefore remove as much old compost as possible without excessive root disturbance, not carrying the reduction too far, and ram the soil firmly. In top-dressing trees in borders the old mulching should be removed, and fresh supplied after loosening the surface. If the trees are growing too luxuriantly a few of the stronger roots may be severed and removed. When the trees grow exuberantly they should be carefully lifted and root-pruned, replanting with the roots near the surface, and well firming the soil. If the trees are unsatisfactory or weakly lift them, remove the old soil, and replant in fresh compost over good drainage.

Training and pruning are the next points to consider. Bush, pyramid, and round headed trees on stems are best for pots or planting-out. Standard trees are unequalled for the latter purpose, and are easily formed by heading at the height required. Pyramids merely require the side shoots pinched and the leader stopped to secure them. Summer pinching may be practised twice or even three times on the leader, and the side shoots once or twice to four or six leaves, avoiding overcrowding the growths, otherwise the fruits are deteiorated for lack of air, and many of the spurs will be too weak to produce fruit, the numerous dead spurs on Plum trees being due to this cause. Pruning may be performed in the spring, as the buds are then easier distinguished by the inexperienced, but as soon as the fruit is gathered is the best time. As a rule Plum trees under glass should be trained for fruit first and form afterwards, that is, pinching, disbudding, and thinning must not be carried too far, for growth is necessary for the production of fruit, its development, and perfect finish. Trees on trellises or walls require the usual summer and winter pruning, but the spur system is not by any means the best for the Plum under glass. The trees being on front or roof trellises are best treated on the alternative system, in which the shoots are allowed to grow up to the glass, only keeping them just clear, these being stopped and kept moderately thin. By thinning out the fruited branches annually, and encouraging shoots to take their places, the trees are maintained in youthful vigour, and the fruit produced is abundant and very fine. Old trees that produce little beyond breastwood and leaves will often yield enormous crops by laying-in young wood, which in the second year will form bloom buds throughout its length and give some fruit, and in the third year a good crop.—G. ABBEY.

PROPAGATING BEDDING PLANTS.

The work of propagating bedding plants has perhaps this year been delayed longer than usual, for the sake of preserving the full beauty of the beds. It should, however, now be pushed on as fast as possible, in order to get the cuttings well rooted before the dull short days come. Judging from the appearance of Pelargonium cuttings, there is every reason to suppose that fine plants, with a small per-centage of losses, may be anticipated, as they are hard, short-jointed, and entirely devoid of the soft sappy growth which predominated last year. These favourable conditions should be taken advantage of by making the cuttings somewhat shorter than usual, so that the plants resulting therefrom may be sturdy from the first. Cuttings with two or three joints will in the majority of

instances prove the best. When placed in shallow boxes a couple of inches asunder large numbers may be wintered in a limited space, but where there is plenty of house or pit room during the winter I would strongly advise inserting the cuttings at once in 3-inch pots. of potting at a busy time in the spring is then avoided, and plants One crock only need be of the dwarfest habit are obtained. placed over the base of each pot, a little rough leaf soil being excellent material to cover this with. Whatever compost is used for filling the pots with, it should be made somewhat light and sandy by the addition of leaf mould and road sand. It is, however, a mistake to use old and exhausted potting soil when this pot system is practised, or the plants will not make progress in A good proportion of fresh loam or moderate rich the spring. A good proportion of fresh loam or moderate rich garden soil should therefore be incorporated with the compost. A sunny position on a bed of coal ashes in the open air is a capital position in which to place the pots after the cuttings are inserted. Should boxes be employed I like to place these on thin strips of deal, so that the air may circulate under the boxes, and thus

prevent loss through damp.

Notwithstanding the great heat of the present summer Violas have flowered so splendidly right up to the present time that we have as yet inserted no cuttings; the work will, however, be in progress by the time these lines are in print. When a sufficient number of young shoots spring from the base of the plants can be obtained we give them the preference, but in many instances these do not suffice to supply our requirements; the points of the old shoots are then used. If these are stopped early in the spring they make good plants. Any varieties which produce very few cuttings may be quite cut down now, the old shoots cut into lengths containing two or three joints each, and be inserted in pans placed in cool close pits. More cuttings will be produced from the old plants by the end of September, and these if dibbled into light soil placed in cold pits will make excellent plants. The Dairymaid, a variety I have grown this year, has been very popular. Early in the season the flower is ivory white, but as the summer wanes the colour is French grey. Countess of Hopetoun is I think still by far the best white variety, indeed, I know of no other hedding plant which makes a colonial white hedding other bedding plant which makes such a splendid white bed during the summer months. All my gardening friends who visit me are glad of a few cuttings of it when they do not already possess that variety. The most of our cuttings are inserted in front of a south wall in the ordinary garden soil, which is rather light. A little road sand is first placed on the surface. are placed a couple of inches apart, and are well attended to in the matter of being watered when they require it. They remain in this position without any protection throughout the winter, and only a very low percentage of losses are the result.

Coleus, Iresine, Alternantheras, Mesembryanthemums, Helio-Cupheas, and similar plants root quickly and easily if inserted in well-drained pots or pans which are stood in a pit or frame, provided they are kept close, syringed once or twice daily, and are shaded from bright sunshine. Should wet cold weather set in the three first named plants, being somewhat tender, will make more satisfactory progress if stood upon a hotbed or in a heated pit, the great point to aim at being to get cuttings of all kinds established as soon as possible after being inserted. To do this they must not be allowed to flag after they are taken from the parent plants. If greater attention were paid to this point we should hear less complants about the difficulty of rooting cuttings of all descriptions.—W. C.

SEASONABLE HINTS ON FLORIST FLOWERS.

THERE has probably never been a season more disappointing to the cultivators of florist flowers than that of 1893. Everything seemed turned topsy-turvy; plants came into flower three weeks or a month before their time, and the dates of exhibitions had to be altered; and now that the end of August has come we are asking ourselves where are our autumnal flowers? The long-continued drought increased the difficulty, and to keep plants in good health

AURICULAS.—These, the earliest of florist flowers, were the first to indicate the normal character of the season; they were out of flower fully three weeks before their usual time, and consequently have had a longer time in their summer quarters than usual. So far as I can see they have not suffered from this. I see few summer deaths among my small collection, but altogether they look well. They have not certainly suffered from drip, for there was no rain to cause it. At present it will be necessary to go carefully through the plants to take off all dead outside leaves, remove weeds, and if there be any aphides either brush them off carefully or fumigate the plants. In about a month's time it will be necessary to remove them to their winter quarters either in pits or frames facing south, giving them all the air possible, but not allowing them to get rain. I have this year reduced the size of the pots in which the plants are grown, and this of course makes the collection seem to be much smaller. I remember successful cultivation being achieved by those who grew in both large and small pots, and am therefore not sure whether I shall gain much by the change.

CARNATIONS AND PICOTEES.—Here again the character of the season has led to very unsatisfactory results, at least so far as my own garden is concerned, owing to the excessive forwardness of the plants, which necessitated the alteration of the date of the Carnation Show. It was necessary to layer very early, for the wood was ripe, and had it been left any longer layering would have been a matter of very great difficulty. It was a choice of two evils, for I feared that too early layering would lead to the layers running up to bloom; the weather of July being wet and comparatively dull was favourable for them, and the layers rapidly

rooted. I now find that my fears were not groundless, as a considerable number have spindled for bloom, and will of course be valueless. It will now be time to remove layers from the plants, for notwithstanding all that has been said as to wintering them in the open ground it is a hazardous thing, and I think it is much better to remove the layers, and pot them and place them in cold frames for the winter. They may be potted either singly or in pairs, and by this method the plants will be very little disturbed when they are planted out in the spring. best to use simple compost in potting; in fact, good loam with a little sand is all that is needed. Where the plants are potted in pairs they should be placed near the outside of the pot; when potted they ought to be removed to a close frame for two or three days, watered, and afterwards have as much air as possible given to them. By the end of September they may be removed into a frame facing south, which can be left partially open night This will, of course, be the proper time for adding to and day. one's collection, and it is remarkable how much more people's minds are turned towards the border varieties than to the old florists' kinds, not that I think that the latter will ever lose their place in the estimation of the true florist; the only thing likely to effect that being the over-dressing to which they are subjected. is almost hopeless to have this remedied, although attempts have been made by offering prizes for undressed flowers to get rid of the practice.

GLADIOLI.—Here, again, the season has sadly interfered; like everything else, they were too early. In the west of England they were mostly over in the second week of August, and here I shall hardly have a flower left by the end of the month, whereas in some years I have had a difficulty in getting a stand for the Crystal Palace on the 6th and 7th of September owing to their not being yet in flower. Notwithstanding the dry weather, or perhaps in consequence of it, they have done better with me this year than One result will be that the bulbs will be sooner fit for lifting than in most years, and this will probably be in their favour for a future bloom; there will be, however, no necessity for inter-The earlier sections of the ference with them for some time. Lemoinei and Nancianus groups will, however, soon be ready, as they are earlier than the Gandavensis section. I do not lift these every year, but protect them with a mulching of some sort. As, however, I did not lift them last year I shall do so now. I have found, singularly enough, that while my unprotected bulbs perished in the winter 1891, thus dispelling the notion of their hardiness, here at any rate, one of them, Duguesclin, has survived, but so have some of the varieties of the Gandavensis, and, therefore, I am afraid neither of the section can be pronounced

PANSIES.—The summer has always been in the South of England a trying time for these plants, as the dryness of our atmosphere does not seem to suit them; they may now contract mildew and perish. I find that many plants have gone off since they were planted out. It will be necessary now to put in small pots any cuttings that have rooted, and to divide the plants, cutting off all straggling shoots and placing them in a cold frame, which should be kept close for a few days until they are rooted.

Roses.—This exceptional season is now drawing to a close, and certainly the last few weeks have wonderfully developed the growth of our plants. I think it is now a very good plan to thin out the weaker shoots and those which have done duty in flowering this year. It gives more air to the plants, and consequently a greater chance of ripening the wood. The long shoots which have greater chance of ripening the wood. sprung up from the base should now be staked to prevent their

being blown about.

I have not included among florists' flowers such as Phloxes, Pentstemons, and other plants which have been by some included amongst them, nor have I said anything about Tulips and Ranunculus, because nothing can be done with them except looking over the bulbs to see that they are not receiving any injury from mildew; neither have I included Pelargoniums or Fuchsias, Neither can I admit which are essentially greenhouse flowers. their right to be included in this division; and yet it would be very hard to say on what principle a Phlox is not to be considered a florist's flower while a Carnation is. But definitions are puzzling things, and I have never met with one about florists' flowers that would go on all fours.—D., Deal.

FACTS AND THOUGHTS ABOUT APPLES.

IT will, in all probability, be a long time before we again have such splendid crops of Apples of the finest quality. Our English grown Apples ought this year to hold their own against all comers, for they apparently possess every desirable good quality, being large, highly coloured, and of fine full flavour. Many varieties

which during ordinary seasons are quite unpalatable in an uncooked state are this year tempting enough for dessert purposes, and those which are generally considered the cream of dessert kinds have a flavour far superior to that they usually possess. I noticed

this a few days ago when tasting several early Apples.

Worcestershire Pearmain, I thought, the best of all Apples of The fruits, the Codlin type, and is unusually good this season. being large and of great depth, are wonderfully attractive in appearance. Lord Suffield is carrying prodigious crops in this neighbourhood, but in many instances the trees canker badly. Stirling Castle is equally productive, but also suffers much from canker; indeed, I invariably notice that trees which are remarkable for their good cropping qualities are the first to succumb to this troublesome disease. Lord Grosvenor seems to be rapidly replacing Lord Suffield in some districts, but hereabouts (Warwick) Manks Codlin will, I think, prove the best early cooking Apple to grow. It is a free and certain bearer, the beautiful golden colour of the fruit renders it more attractive in appearance than those cooking kinds above enumerated. In the gardens here the trees show no traces of canker. Ecklinville, Keswick Codlin, and Hawthornden have also very heavy crops; the former variety grows more freely than the majority of early ones, and suffers but little from canker. The latter should be extensively grown for home use, as it is frequently preferred to other cooking kinds on account of its brisk and somewhat sharp flavour. Golden Spire is a variety which I think ought to be more extensively planted. In appearance it is extra fine, crops well, and ripens a little later than Lord Suffield. I do not remember ever having previously seen such good crops of Warner's King as I have met with this year. At the Castle Nursery Mr. J. Kitley recently showed me two large bush trees carrying grand specimens of this fine variety. A noteworthy fact in connection with them was that the branches were bearing freely quite in the centre of the Mr. Kitley is a great believer in the practice of thinning the branches freely and leaving them unshortened, and he considers his success in Apple culture is in a great measure due to the fact that he adopts this method. Very heavy crops of Devonshire Quarrenden are this year prevalent around Warwick, and that favourite local variety Wyken Pippin is also abundant. Cox's Pomona nor Cox's Orange Pippin (which with me usually crop well), is this year very productive. On the other hand, standard trees of Irish Peach, King of the Pippins, Worcestershire Pearmain, and Kerry Pippin are loaded with fruits.

At one time Apples of all kinds promised to be undersized, but

since the late rains a wonderful improvement has taken place; and considering the heavy crops the trees are carrying many of the fruits are remarkably large. These being ripened under the influence of brilliant sunshine are firm, sound, and good in colour, so that we may reasonably look forward to their keeping well. Considering how very early gathering has to be commenced this year it is well that the fruit can be stored in good condition. Every possible care ought also to be exercised in storing, so as to prolong the supply as much as possible. In seasons like the present one, when Apples are so plentiful, the fruit room proper will seldom accommodate the whole of the crop. The early varieties may then be conveniently stored in sheds and outhouses, in which positions they generally keep in good condition if placed in

thin layers and kept cool and dark.

It seems to me that too many early varieties have during recent years been planted, with the result that our markets are glutted with Apples, which must be disposed of because they will not keep. In a season like the present this is especially apparent. What we want is a greater bulk of such late-keeping kinds as Sturmer Pippin, Lane's Prince Albert, and Northern Greening. It is scarcely possible to say too much in favour of the first of this trio, as it is a consistent cropper. The fruits will keep perfectly sound and fresh till June, when it is good for both culinary and dessert purposes. I shall be much mistaken if the abundant yet early Apple crop of 1893 does not have the effect of causing fruit growers to devote more attention to very late kinds, with which I am sure they may successfully compete against those sent by our kinsmen in the Antipodes.—H. Dunkin.

SOFT VERSUS HARD COLD WATER.

It is seldom that I do otherwise than content myself by pondering over the pages of the Journal of Horticulture, reading the practical and interesting articles from the pens of so many good writers, in most cases sound and reliable authority; so that in taking up my pen to defend one of my secret ideas, which in a recent issue your correspondent, "W. P. W.," has thought right to divulge, I may be pardoned for any slight misgivings that naturally arise in publicly accepting the responsibility of an "eccentric idea," if such it can be proved. I am still under the impression that "W. P. W." has launched his boat upon a troubled sea, and will find it difficult to steer a straight course to convince a practical gardener that "hard cold water" is little better than slow poison to vegetation in general. The nourishing qualities of "hard cold water" are rendered easily perceptible if constantly followed

by watering plants either in pots or planted out.

We will turn for a moment to the forcible query "W. P. W." confronts us with—viz., "What, I wonder, would the many persevering amateurs do whose plants never receive any except hard water?" If this statement means "hard cold water" direct from tap or pump, then my compassion for such plants is fully aroused, and my advice to those persevering earnest men who endeavour to keep vitality in their plants by such means is, Abandon the idea. My answer to "W. P. W.'s" query as to what those earnest amateurs would do is rather difficult to frame. What they ought to do is easily answered—viz., those who are living in towns, and have only "hard cold water" at command, ought, in the first place, to procure a tub or cistern, and fix outside fully exposed to the air, and in such a position to catch the full power of the sun's rays for a few hours during the day. This will be found to act wonderfully upon the water. Nature, in this particular instance, teaches most indisputable lessons which no theoretical knowledge can dispel. Is not vegetation in due season nourished with showers and warmth according to their wants—warm showers in summer, cold showers in winter? Therefore, those who are guided by Nature's laws in respect to water that must be artificially used will reap the surest and greatest reward.

I claim that water used within a few degrees, more or less, of the temperature of the soil to be moistened, is the truest guide to administer nourishment to plants. "Hard cold water" used constantly during the height of summer, produces a pale, stunted, sickly appearance upon vegetation in general, and so attracts insects and diseases which might otherwise be a verted by timely thought and a little extra trouble, which would be doubly repaid. Such water is not only injurious when admitted to the roots of plants, but it is detrimental to the foliage if used for syringing during the summer. Take, for instance, a Peach tree infested with red spider. It is an impossibility to thoroughly eradicate this pest with "hard cold water," yet by constantly using soft or rain water this troublesome insect can be mastered.

In conclusion, allow me to assure "W. P. W." upon his closing remarks (page 168), that gardening with all its difficulties might be made far more enjoyable, especially during such a trying season as we have passed through, if gardeners and amateurs could but realise the value of soft water, or hard water rendered soft and warm, as a nourishing, health-producing stimulant to vegetation in place of the easily obtained obnoxious drug, "hard cold water." I now leave the subject in the hands and minds of readers of the *Journal*, and "W. P. W." in particular, to prove by practical demonstration that my ideas are whimsical, and that I am deviating from established forms before I accept the term "eccentric."—F. Dunn.

THE SPARROW QUESTION.

WITH due respect to Mr. J. Witherspoon (page 177), the facts which I quoted (page 145) seem to test the strength of his faith to the utmost. Thus squeezed he becomes fierce, and tries vainly to overturn them. He may call us his opposers what he likes, "selfish, short-sighted, wrathful, &c.," because we do not love the ways of the sparrow. He may scornfully ignore and condemn the charges made against these destructive birds, but where is he going to stand while he thus throws dust into the eyes of truth? I know he stands alone, for he fishes for recruits. He throws his hook and line across Mr. Editor's path with a tempting bait of persuasion at the end of it, but this discreet gentleman quietly lets it float and does not bite. Like a defeated marshal on a battlefield Mr. Witherspoon stands alone, his rakish regiments having been shattered, not by the ammunition of those "good deeds," but by the explosive power of those "little mistakes" (as he terms them) so apparent in the scoundrel sparrow. I consider your correspondent both unjust and inconsistent in his endeavour to defend these birds.

Charge 1 (page 145), he submits (though very reluctantly) to be a learner and, as he says "that he is rather inclined to think that the

charge will be true.'

Charge 2. He disbelieves that these birds are enemies to gardeners and fruit growers. He denounces the grand volume of the American Agricultural Report as mere "scraps," throws it one side and puts his small, comparatively speaking, "experience" in its stead. Age does not always indicate the width of experience, and younger persons often possesses more experience than their elders in some things

Charge 3. He screens the sparrows with the feathers of hens, ducks, I blackbirds. We all know that Grape culture in our country is not and blackbirds. carried on like that of America; but this does not impugn the accuracy

of the report.

Charge 4. Here, "J. W." takes refuge in cities, and describes sparrows as "scavengers" which pick bones and clear away refuse; but grain and fruit buds do not grow in cities for the scavengers to destroy. Perhaps suburban amateurs will describe the good (or harm) that sparrows do in their gardens.

Charge 5. Here your correspondent modestly suggests that Miss Ormerod's researches and overwhelming evidence are nothing to his own "experience." Miss Ormerod's evidence was gathered from a hundred sources; Mr. Witherspoon's, so far as we know, in one garden. Can he give the names of gardeners under whom he was trained, and who taught him his (unsupported) doctrine that sparrows do far more good than harm in the majority of gardens and fields?—DAVIES DUFFRYN.

CYPRIPEDIUM SANDER-SUPERBIENS.

THE first Cypripedium Sanderianum hybrid which has yet appeared was exhibited by Mr. Cookson at the Agricultural Hall on August 29th, under the above name, and received an award of merit. The other species employed was C. superbiens, and the credit of the cross belongs to Captain Vipan, the hybrid having been raised by Mr. Cookson from seed supplied by the former. It is a beautiful and distinct form, the flowers being of great size, and remarkable for the very long, drooping petals, which are double the length of the lip. They are pale yellow in colour, heavily blotched with chocolate. The lip is brownish red, and the dorsal sepal, which is pointed, greenish white with chocolate lines. Fig. 31 represents this fine acquisition. Mr. Cookson has followed a distinguished lead in respect to nomenclature; but such a name as Sander-superbiens is not euphonious, and forms a quaint mixture of English—or ought we to say German?—and Latin.

AERIDES SANDERIANUM.

Two of the largest-flowered and handsomest of all Aërides are this and its near ally, A. Lawrenciæ. "Broadly speaking," says Mr. W. Watson, in a recent issue of the "Garden and Forest," "they are only varieties of the old garden favourite, A. odoratum, but their flowers are nearly as large again, and their leaves broader than the ordinary form of that plant." At Kew, A. Sanderianum is represented by a plant a yard high, clothed with healthy foliage to the base, bearing two flower-scapes, each 18 inches long and clothed with twenty-five flowers, which are $1\frac{1}{2}$ inch in diameter, creamy white, tipped with amethyst, and deliciously fragrant. It is nearly ten years since Messrs. F. Sander & Co. introduced this plant in quantity from the Philippine Islands along with A. Lawrenciæ, the first plant of which was purchased at an auction sale by Sir Trevor Lawrence for 235 guineas. It differs from A. Sanderiana in having pure white, instead of creamy white, flowers with amethyst tips.

ODONTOGLOSSUMS.

These have been in many cases heavily shaded during the past summer, but the material should be gradually dispensed with, the blinds being drawn down for a few hours only during bright sunshine. As much light as possible ought now to be admitted, and where the shading is of a permanent nature lose no time in washing the greater portion of it off. It will not be safe to remove all at once, or injury may result if bright weather follows. Shading of this nature is not, however, advisable for Orchids. Considerably less atmospheric moisture will be needed, and also about the roots of the plant, but on no account allow the atmosphere of the house to become dry, or the soil at the roots of the plants.

Press down the moss if it has grown above the base of the pseudo-bulbs. Wash the pots in which the plants are growing, as well as those upon which they are elevated. Slugs can frequently be found when turning over the plants. Wash the glass and woodwork of the structure in which they are grown, and limewash the walls. Do not allow the temperature to fall below 50° at 6 A.M. Artificial heat only will be needed during cold nights for some

weeks longer.—Specialist.

PARAGRAPHS ABOUT THE PARKS.

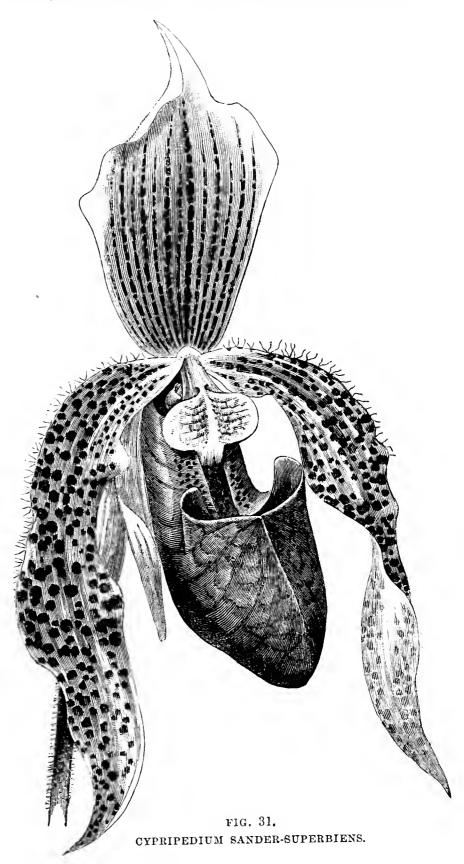

WHATEVER may be said, for or against, about the London County Council, it is generally admitted that they have effected great improvements in the parks, gardens, and open spaces of the Metropolis. They have added fresh lungs to the system, strengthened others, and improved the condition of the huge patient in a manner very pleasant to behold. True, the drought has set at naught their efforts to clothe the commons and other public places with smooth greensward, but that detracts nothing from the credit due to honest and enlightened endeavour, and the authorities undoubtedly have at the head of this important department a most competent and zealous official in Mr. J. J. Sexby.

BATTERSEA PARK.

The south-west of London has had its fair share of the benefits which followed the fall of the old Board of Works. Wandsworth Common has been quite transformed. Fresh turf has been laid, new walks have been made, old furze cleared off and young established, lakes formed, and seats provided. Battersea Park has also been improved. It has been put under the charge of one of the most capable superintendents which any of the London parks have yet had

in Mr. Coppin; the staff has been increased, cricket pitches have been re-made, lawn tennis grounds provided, and the floral attractions of the place largely augmented. Battersea has reason to be proud of its park, and very likely it is. Let us hope that the efforts of the Council have not gone altogether unrewarded by gratitude and appreciation. This park always enjoyed the reputation of being one of the most attractive in London, and of late years its claims have grown stronger. It enjoys a unique position, on one side of it swarming a dense industrial population and on the other being the river.

Visitors of a gardening turn who would like to have a good look round the park and see most of what is to be seen in the flower way,

would not err by entering at the south-west gate and following a systematic round. Perhaps they will run over it with me in imagination first. Two beautiful borders stretch away right and left on entering. They are 6 or 7 feet broad, and as long as I can remember have been one of the brightest features of the park. Although they have had the wear and tear of an exceptionally trying season they are still looking well, being bright with Dahlias, Sunflowers, herbaceous Phloxes and Anemone japonica alba at the back, and in front of these with Beet, Petunias, Stocks, Lilium speciosum, annual Phloxes, Violas, Zonal Pelargoniums, Sedum spectabile, Coleuses, Asters, Campanulas, Tagetes, Calliopses, Gaillardias, Pentstemons, and many other flowers.

The drive on the left hand may be followed as far as the north-west entrance, when a turn to the right along a broad drive near the riverside will bring us to a group of coffin-shaped beds converging to a central circular one. Before coming to them a circle is observed planted with

Begonias and various Coleuses, mixed with Lobelias. Six of the coffin-shaped beds are planted as pairs, and have filled out extremely well. One pair is planted with Begonias in the centre, interspersed with a Nierembergia gracilis, a graceful plant that likes hot weather. They are flanked by lines of Golden Harry Hieover Pelargoniums and Lobelias. A second pair are planted with blue Violas and a silver variegated Zonal in mixture, with an outer line of Iresine, and a margin of what appeared to be variegated Thyme. Less common, but even more effective, are white Antirrhinums mixed with Amaranthus melancholicus ruber, and with an outer line of Robert Fish Pelargonium. These are beautiful beds, and the combination is a very simple one. A dark Coleus would show up the Snapdragons as well as the Amaranthus does.

In passing on it is impossible to help observing the admirable neatness and order which prevail. The turf is excellently kept, the borders clean and in good order all through. Naturally the leaves are giving a great deal of trouble just now; they are falling early and rapidly, and are being raked up into heaps and burned. A very attractive corner is found near the refreshment room in the same drive. A broad border and series of beds occupy the inside of a semi-circle. If one had been tempted to think a visit at the end of August too late in a season like the present he would be undeceived by the time he had seen this picture, for it is difficult to imagine that it could ever have been more beautiful than it is now. The border is brilliant with Beet, Marguerites, scarlet and other Zonals, Calceolarias, white Snapdragons (beautiful as before), Lobelias, and Echeverias. Two or three of the beds are carpets, neat in design, well filled, and admirably kept; others are composed of hardy Fuchsias mixed with Heliotrope, and edged with Lobelia and Sempervivum tabulæforme.

At this point it will be well to turn to the right and pass through the central walk to the sub-tropical garden, which has been for many years the crowning glory of the park. It is splendidly effective this season. There is a pleasant irregularity of level and outline about the ground, and both beds and material for planting them are diversified in character. In one there is a bold group of Cannas; in another Begonias mixed with silvery Dactylis and edged with Zonals, Lobelias, and Echeverias; in a third (an oblong) Eucalyptus globulus 8 to 10 feet high rises above the marbled foliage of Abutilon Thompsoni, and there is the usual margining. Another bed quite as effective in its way as any of the others is planted with Lobelia cardinalis rising from a mass of Ivy-leaved Pelargoniums, with Violas and dwarf succulents outside. The tall scarlet spikes of the Lobelia are very striking. Then there are beds of Dahlias, beds of Bamboos, beds of carpet plants, beds of succulents, beds of Ricinus (very effective these in their greens and purples), beds of Lilium speciosum mixed with Stocks and many others which cannot be enumerated. Go and see, that is the best advice which can be given. The Battersea sub-tropical garden is as fine a feature as any park in the kingdom can boast of pessessing, and just outside it, leading to the lake, the Palm dell and grove are unique.

Bearing to the right and then abruptly to the left we get the lake on the left hand and follow it as far as the south-east gate, near which there is a very large rectangular bed filled with Phloxes, Lobelia cardinalis, Anemone japonica and its white variety, early Chrysanthemums, Gladioli, and a host of dwarfer plants. With the borders beside it, it forms a most brilliant and striking picture. A ramble up the side of the park to finish the inspection at the north-east gate will reveal many bright corners and gay borders, in fact there are few dull moments in the little tour. Battersea Park is a favourite resort of thousands of workers in the vicinity, and adds to the benefits of pure air the wholesome lesson of the beauty and cheerfulness of flowers.

If the Chrysanthemums fulfil their present promise there will be a splendid display in a few weeks' time, for there are about 2000 plants of a type which good growers admire best. They are stiff and sturdy, with stout, brown stems and substantial foliage, the growth ripening admirably. A number of buds have been taken, but it is not expected that the blooming will be appreciably earlier than usual. No matter, so long as it is good, and of that there need be little doubt. The show, we believe, opens about the middle of October.

HYDE PARK.

As every Londoner and many country visitors know there is a tremendous difference between the surroundings of Battersea and Hyde Parks, the latter being in the very heart of the fashionable quarter. It is not my intention to form any comparison between them, because they vary greatly in every way; but as a few notes have been devoted to the floral features of the one so brief references may be made to those of the other. Country gardeners often find a difficulty in arranging for a sufficient change in their flower beds to satisfy themselves and their employers season after season, and they are sometimes glad to have their attention called to combinations elsewhere, which, with a little rearrangement to meet local conditions, will provide the desired variation.

Hyde Park is extensive, and the bedding, especially near Park Lane, is splendidly carried out; but there is one little matter in which there is room for improvement, and that is in the prevailing bareness at the Marble Arch. There is a short border of flowers on the left, but it is round the corner, practically out of sight from the road, so that passersby and those entering the Park here have nothing bright and cheerful

to greet them. As a number of paths diverge just opposite the Arch there is a difficulty in providing for broad borders, but a little group of beds established on the grass just behind them might be provided, I think, and they would make the entrance much more attractive and pleasing than it is now. With a modest suggestion to that effect I pass to say a few words about some of the beds.

Those who want to see the best of them should turn to the left inside the Marble Arch, and walk down parallel with Park Lane, past Grosvenor Gate, towards Hyde Park Corner, or vice versâ. Here magnificent stretches will be found, varying in shape, size, and design in a degree sufficient to satisfy the most exacting critic. One of the first to be seen is composed of Fuchsias rising above early Chrysanthemums and Asters, with outer lines of Iresine Wallsi and Alternanthera aurea nana. This would be a beautiful bed were the Fuchsias good, but unfortunately they are somewhat thin, and this is the case in most of the other beds in which they are planted, although there are one or two noteworthy exceptions, of which more later. A second bed is composed of Abutilons, Celosias, and Dracæna rubra in mixture, carpeted with Alternanthera aurea nana, and lined with Colcus splendens, Lobelia Snowball, and L. Omen in three separate bands. This is effective, and would be more so if the Abutilons were better bloomed.

There are several examples of the Pelargonium-Viola mixtures. One is composed of Mrs. Pollock and Blue King, with Lobelia and Pyrethrum aureum laciniatum. Another is a combination of Pelargonium Princess Alexandra and Viola Lilacina, with Swanley Blue Lobelia and the Pyrethrum; but this group is nearly surrounded by trees, and it is evident that they have told against the beds considerably. They have spoiled a well-designed bed that ought to have been very attractive. It is composed of Grevillea robusta, mixed with Carnations on a groundwork of True Blue Viola, but the last named has done very badly. The outer lines are Lobelia Omen and Lysimachia Nummularia aurea. A passing tribute ought to be paid to the admirable system of naming the plants which is adopted. It must be instructive to the public and useful to those horticulturists who, not being Kew experts, are unable to recognise every plant in the world at a glance.

The main block of beds is just by the Grosvenor Gate on the Piccadilly side. There is a wide oblong stretch of greensward with a path on each side of it, and the beds are arranged in pairs, one at the side of each walk. It is well to keep the oblong on the right, going in the direction of the Corner, as then the long line of beds near the park railings may be inspected at the same time. All have done much better than the first group; with hardly an exception they have filled out well, and the designs are both varied and beautiful, so that it is a true delight to study them. All of course are not equally pleasing to one pair of eyes, but tastes differ, and what one visitor condemns another would approve.

Attracting attention is a very beautiful bed formed by the simple admixture of scarlet Tuberous Begonias and Acacia lophantha, with a groundwork of Lysimachia Nummularia aurea and an edging of Lobelia Snowball. There is nothing elaborate or difficult to imitate about this, but it would not be easy to excel it. Another that is strikingly effective is made up of splendid pyramids of Heliotrope General Garfield 4 to 6 feet high, $2\frac{1}{2}$ to 3 feet through and full of bloom, mixed with Lilium speciosum and Nicotiana affinis, the carpet being Alternanthera aurea nana, the outer lines A. paronychioides major and A. amœna. It is rich, bold, and imposing.

Two delightful beds have been formed by associating Tuberous Begonias with Grevillea robusta. One is the crimson variety Chas. Baltet, its flowers being well set off by the foliage plant, and the bed is carpeted with Harrison's Musk, a broad band of Viola Snowflake completing it. In the other the pink Begonia Lady Stanhope is used. These are two of the most successful mixtures in the park. There is one bed in which Fuchsias are growing and blooming beautifully. The tall plants, with their pendant flower-laden shoots, droop gracefully over a mixture of Abutilons, double Petunias, and Begonias, a border of Mesembryanthemum cordifolium variegatum completing an effective arrangement.

A simple combination that is likely to please most persons is a scarlet Zonal mixed with the lilac Viola Bessie Clark, these being surrounded by a band of the dwarf yellow Fuchsia Cloth of Gold half a yard across. Scarlet Begonias rising from a carpet of the golden Creeping Jenny, and margined with the bronzy Fuchsia Meteor, also look extremely well. Between and amongst these beds are huge Palms, groups of Eucalyptus globulus, hardy Fuchsias, pyramidal Heliotropes, and columnar masses of Plumbago capensis 8 feet high, all of which serve a useful purpose in breaking up the lines and imparting diversity.

Shortly after this grand group is quitted another is reached on the left, and in it a few of the best mixtures are (1) hardy Fuchsias, Lilium speciosum and Celosias, with a groundwork of blue Lobelia; (2) Ivyleaved Pelargonium Mdme. Crousse in fine masses, with early Chrysanthemums and Violas; (3) dwarf Cannas, with Acacia lophantha, Grevillea robusta, and Indiarubber plants, carpeted with Alternanthera; (4) a rose Begonia on a groundwork of Mesembryanthemum cordifolium variegatum, edged with Coleuses and white Lobelia. Soon after these beds are passed a sharp turn to the right will lead to the dell near

the Serpentine, where a winding stream meandering between Ivy-covered banks to a rocky head lined by tall Tree Ferns and lofty Musas is well worth seeing. From here to Hyde Park Corner, as well as along the Lady's Mile, there are several attractive beds and borders to be found; but probably enough has been described to serve the purpose of indicating the beauty of the great park under the masterly superintendence of Mr. W. Brown.—Wanderer.

FRUIT GATHERING TIME AT CHEALS'.

BETWEEN the end of budding time and the commencement of the lifting season there is a little lull in the fruit nurseries, not a complete one by any means, for there is plenty of work still on hand, but just a trifling relaxation of the pressure which seems almost a chronic condition in rising places. It is then that the wise man will pay his visit if he can. In early September many trees have been relieved of their golden or crimson load, gatherings having been made in order to secure fruit for the shows, but the majority remain with the greater part of their crop, and so their bearing qualities may be perceived. The season of 1893, so harrassing and even deadly to numerous light-land cultivators, has dealt kindly with those great growers Messrs. J. Cheal & Sons of Crawley. No hungry, thirsty soil is theirs, but heavy, tenacious loam, and while in thousands of places trees have languished and dropped their fruit, Conifers wilted, and shrubs shrivelled, at Lowfield their growth has been steady, substantial, and healthy. I have more than once inspected the famous nurseries, but have never seen them in such condition as they are this season. The weather has given such an opportunity for weed extermination as we have not had for many a year, and it has been taken advantage of to the full. Acre after acre may be traversed without one weed being scen. In order, cleanliness, and neatness the nurseries are perfect, while above and beyond all there are the thousands of healthy, vigorous trees which are to go forth and bring fresh credit to the name of Cheal when the season comes round.

THE OLD ORDER AND THE NEW.

It is impossible to help contrasting the present with the past. A quarter of a century ago this fruit and shrub nursery of about 100 acres, employing its scores of hands, was under farm cultivation, and for every man who then found occupation there is now work for a dozen. The value of the land has grown enormously, the prosperity of its cultivators has increased, and the condition of the workers has correspondingly improved. These are gratifying facts. Development was steady and gradual until ten or fifteen years ago, since when it has gone on with accelerated speed, good material and good workmanship securing the general recognition which has now placed the once small local firm in the front rank of British nurserymen. Though the Crawley soil is holding and stubborn, like John Bull's own character, it has sterling qualities, building up strong and seasoned growth well calculated to fight its way into matured health, strength, and fruitfulness. There is something fresh and invigorating, too, in the Crawley air, alike to vegetation and mankind, for in addition to splendid trees and brilliant flowers, Lowfield possesses in the nonagenarian parent of the wellknown brothers, a wonderful specimen of humanity. Mr. Cheal, senior, now in his ninety-fourth year, still gazes on the scenes which have been familiar to him for nearly a century with faculties undimmed, enjoys life, and astonishes the doctors, who long ago dubbed him "the evergreen," and left him to his own marvellous vital resources as requiring no help from them. To hear him speak with fatherly pride of the energetic and enterprising brothers who have lifted the business up by hard work and sound methods, and have grown grey in the work, as "my boys," and then to glance out over the acres of fruit and mentally contrast them with the old corn-growing order of things, brings home the contrast of the generations. In the hurry of progress let us not forget the firm foundations of the past.

A House of Cordon Pears.

But the present is too pressing to afford much time for retrospect. I went to Cheal's to report their work and progress up to date, and I must set about my task. First, a few words may be devoted to the house of cordon Pears, which is now one of the great features of the nursery. It is 50 feet long, 20 wide, and 12 high, the rafters going down to within a foot of the ground, where there is a continuous shutter at each side, raised in genial weather to admit a flow of pure air amongst the trees. The structure, it will be understood, is a very light one. Bush trees are planted in a central bed, and all round the house are trained cordon Pears. They have been planted out in the border and allowed to go right up the roof, which permits a run of about 15 feet. They are now in their third year, and are a very striking and instructive sight, being laden with magnificent fruit. A good deal has been cleared off, but there is still a crop hanging which speaks with eloquent voice of the benefits of the system. Here, with the trees under easy control and the blossom protected, an annual crop is insured. They not only bear splendid fruit now, but exhibit in the bold buds with which they are bristling the promise of an equal crop next season. Amongst them are new and old varieties. Duchesse de Nemours is a January Pear resembling Doyenné Boussoch in appearance, and of excellent quality. Belle de Bruxelles and Duchesse de Mouchy are both bearing well, but neither is much known generally. The latter keeps till March. Then there are Charles Cognée, a useful February Pear; Beurré Alexandre Lucas, Princess, in grand condition; Epine Dumas and Abbé Fetcl,

which has grand clusters of large fruit. Amongst the older varieties Beurré Superfin, Beurré Hardy, Uvedale's St. Germain's, Doyenné Boussoch (very fine), Maréchal de Cour, Louise Bonne of Jersey, Durondeau, Jersey Gratioli, Clapp's Favourite, Triomphe de Jodoigne, Beurré d'Amanlis, and General Toddleben are carrying splendid crops, the last-named being one of the best. There is one notable disappointment, however, and that is the delicious Doyenné du Comice, which so far does badly, the fruit being brown and scabbed. The cordon house is undoubtedly a great success, and attracts the attention of all visitors. In due time similar structures will doubtless be found in many private places.

CORDONS OUT OF DOORS.

Although the drought has been so prolonged and insects so troublesome the trees, as I have said, arc in admirable condition. The insect plague would have developed into a very serious matter but for being dealt with in a firm manner. For many weeks two hands were constantly employed in the application of insecticides, and as labour means expense the task was a costly one, but the result was that the mischief to the trees was arrested, and they have gone on well ever since. The Crawley cordons are famous, and in few previous seasons have they been seen in such splendid order. Apart from the walls, espaliers, and arches, each with its ripening burden, there are excellent crops both of Apples and Pears in the open quarters. The latter are surprisingly full, the blossom escaping injury from the spring frosts as it rarely does. A good deal was destroyed, but plenty escaped. Beurré d'Amanlis, Williams' Bon Chrêtien, Williams' Victoria, a later variety than the last named; Passe Colmar, Marie Louise d'Uccle, Fondante d'Antomne, Doyenné du Comice (exceptionally good), Durondeau (ditto), and Beurré de l'Assomption may be named as a few that are bearing heavily. These trees are not topped, but the side shoots are shortened to encourage the formation of fruit spurs, with which they are thickly studded. They are clean, vigorous, healthy, and fruitful, and no one inspecting them would hesitate to entrust his fortunes to them if he were desirous of planting. It is not in vain that Messrs. Cheal & Sons have devoted special attention to this popular and rising class.

NOTES ON VARIOUS APPLES.

"Why," said Mr. A., "don't people grow more of Hormead Pearmain?" and then he looked at Mr. J., and the latter responded, "Ah! Why?" It is one of the best Apples grown at Crawley, being a fine and constant cropper, a good grower, and bearing beautiful fruit. It is an excellent kitchen sort, and may also be used for dessert. The neglect of this variety apparently rankled in Mr. A.'s mind, for an hour or so after he returned to it, and this time clinched the matter by saying emphatically that if he were going to grow six varieties this would be one of them. Will not some growers try it on the strength of this, and report results? Then there is the Forge, a small local Apple, wonderfully heavy for its size, growing freely in almost any soil, never cankering, bearing every year, hardy, healthy, and an admirable cooker. It has exceptional colour this year, but is always attractive, though hardly large enough for market. Waltham Abbey Seedling and The Queen are yielding grand fruit on young bushes. Jefferson is a small and attractive dessert variety, the skin striped and flaked, the fruit somewhat flattened, borne freely, and of very agreeable flavour. It does well as a cordon. Landsberger Reinette is bearing fine crops both as a bush and a cordon. Sussex Nanney, a mid-Sussex dessert Apple with soft flesh, ready now, is not widely known, but merits recognition.

An Apple which is puzzling not a few experts is one had under the name of Ringer. It is not that, for although the yellow fruit bears a strong resemblance to it, it is much heavier and the stalk shorter; the tree crops better than Ringer too. Several have thought it to be Jolly Beggar, but the foliage is quite distinct from that and the stalk shorter. If it could be pronounced a distinct variety it would be well worthy of a name, for the fruit is wonderfully solid and heavy, keeping well, and the tree is a great cropper. Sandringham, Lady Henniker, Maltster, Frogmore Prolific, Margil, and Lord Lennox are all observed to be bearing well. Young trees of Lane's Prince Albert, open, clean, healthy bushes, are almost breaking down with their load of splendid fruit. The colour that many varieties possess this season is altogether exceptional. With the warm air and soil they have assumed the richest imaginable tints, Cox's Orange Pippin, Beauty of Kent, Cellini, Barchard's Seedling, Bismarck, Gascoyne's Seedling and Wealthy being particularly brilliant. The season has brought about noticeable changes in some varieties. Peasgood's Nonesuch is not so large as usual, and Ecklinville far from being so good as it generally is; on the other hand Cellini, usually one of the worst at Crawley, is grand both in crop and colour this season, and Lord Suffield, another of the troublesome ones, is also excellent in every way. A splendid stock of Bismarck arrests special attention and orders are beginning to flow in for it rapidly. Cospatrick, Newton Wonder (an improved Wellington), King of the Pippins, Betty Gecson, Claygate Pearmain, Mannington, Dutch Mignonne, and Domino successively arrest attention for their healthy growth and enormous crops. Newton Wonder, Betty Geeson, and Domino all stand very high in Messrs. Cheal's estimation, and all must grow in popular esteem from their intrinsic excellence.

THE DAHLIAS.

It would be useless to attempt an exhaustive reference to every object of interest in the fruit way at Lowfield, so I give in at once, and pass on to say a few words about the Dahlias, which constitute the other great speciality of the firm. There are several large quarters of

them, one being devoted to Shows and Fancies, another to Cactus and decorative, a third to Pompons, and a fourth to singles, besides borders of Tom Thumbs. They were in full beauty, and produced a magnificent effect, hundreds of thousands of brilliant flowers dazzling the eye. A choice dozen of the Cactus and decorative group, worth growing everywhere, are Delicata, Robt. Cannell, Mrs. Peart, Ernest Cannell, Sir Roger, Duke of Clarence, Beauty of Arundel, Bertha Mawley, Crawley Gem, Edith Cheal, Countess of Radnor, and Duchess of York. The purely "decorative" varieties will soon be out of date. Twelve splendid Pompons, chosen from a most extensive collection, are Sunshine, Arthur West, Boule d'Or, Tommy Keith, Phœbe, Geo. Brinckman, H. G. Searle, Grace, E. F. Jungker, Whisper, Eurydice, and Lady Blanche. A dozen beautiful, distinct, and free-flowering singles are Formosa, Gulielma, Northern Star, Eclipse, Amos Perry, Evelyn, Miss Glasscock, The Bride, May Sharpe, Aurora, Duke of York, and Kitty. The Tom Thumbs are flowering freely and brightly, particularly Mignon, Bantam, Houp-là, and Canary.

I had wished to make some reference to the trees and shrubs, but must leave them for the time at least. The Dartmouth, John Downie, Transcendent, and Red Siberian Crabs, Prunus Pissardi, the Thorns, the Acers, the Golden and Cornish Elms, and the Conifers are pictures of health and beauty. No one need wish for a finer stock. They form with the fruit trees a monument to the success which has followed a long and arduous struggle with a stiff, unkindly, but withal fertile soil. Energy and determination, supported by cultural skill, have proved the conquerors, and a fiftyfold increase in the productiveness of the land is at once the reward and the justification of those who have triumphed.

NATIONAL ROSE SOCIETY.

I AM confident that whatever other effect my circular may have produced, it is a pleasure to have drawn so reticent a man as Mr. Mawley into an active correspondence in your Journal. One would think from Mr. Mawley's letter on page 201 that I had issued a series of questions involving charges of the most terrible character, as his reply contains such expressions as "fearful crime," "searching examination," "spotless record," and other terms which are suggestive and certainly invite a reply.

Let us see then how others look on the management of the Society. A writer in a contemporary (whose identity I am unable to fix), under the appropriate pseudonym of "Lux," says "there is a strong clement of conservatism in nearly all these special societies, and the general plan is to get everything cut and dried at a nice tea party sort of meeting." I think "Lux" accurately describes the Committee meetings of "our beloved National Rose Society"—a stock phrase of endearment peculiar to "E. M.," who will presumably be glad to answer a few questions that I will put to the Secretaries.

1, Does either of these gentlemen know of any Society of standing whose Committee meet to transact business once a month, and manage to properly discuss the affairs and current work of the Society in the space of about one hour?

2, Do the Secretaries know of any Society whose members are enrolled without any election, who prior to enrolment are asked no questions, and for whom no one is responsible?

3, Would the Secretaries say how many inquiries they received as to the "character" of my private circular, the receipt of which inquiries they state urged them to make the circular a subject for public notice and repudiation?—CHARLES J. GRAHAME, Croydon.

TEA ROSE ERNEST METZ.

I HAVE sent some blooms of the above Rose for your inspection, and probably you will agree with me that it would be difficult to name any other kind more beautiful at this time of year.—BENJAMIN R. CANT.

[We do agree with our correspondent in this respect. The blooms were beautiful, being deep, large, handsome, delightfully fresh, and of a delicate blush pink, shaded carmine at the edge of the petals. Obviously Ernest Metz, like the majority of Roses, thrives at Colchester.]

TEA-SCENTED ROSES.

I AM much obliged to "D., Deal," for the information he gives me in your issue of last week. I have, however, been for some time familiar with the fact that L'Ideal is a Noisette (hybridised, nevertheless, with the Tea-scented class, and therefore closely allied to these); likewise that Cheshunt Hybrid—a Rose which ought, if only for its fragrance, to be valued more highly than it is by exhibitors—is a Hybrid Tea. I am interested to find that your correspondent assigns to the same category Gustave Regis, which is one of the most beautiful of modern Roses, especially when in bud. At this stage of development it rivals L'Ideal and William Allen Richardson. Noisette and Tea Roses succeed admirably in my garden (Wigtonshire) grown in the open air, and they require during the winter but little protection. Among these are those somewhat delicately constituted vo victies of the Noisette class, Maréchal

Niel and Cloth of Gold. But then we are encircled on all sides (save one) by the sea, and have from the Atlantic the mitigating influence of the Gulf Stream.—DAVID R. WILLIAMSON.

Rose-growing and Pressing in Saxony.

THE experimental Rose plantations started two years ago in the neighbourhood of Leipzig have given such brilliant results that they are, the Belgian Consul states, being extended. The plants have thriven well through the long and severe winter of 1892-93, and their condition in May left nothing to be desired. It has been shown that it was a false idea to suppose that these flowers require Oriental heat to prosper and acquire a delicate perfume; the experiments at Leipzig having proved that a cool temperature, and even a little damp, is the first condition of a good yield, whilst great heat is the enemy of Roses. A special factory has been established in the middle of the plantations by the house which made the first experiments, and it is to be put in operation this summer. Provision is made for dealing each day—we quote the Consul—"with 50,000 kilogs of leaves, "producing, at least, about 40 kilogs of oil, water, and pomade of Roses, valued at 40,000 to 50,000 marks. To start with the factory will have three boilers providing 300 square metres of heated surface, and the Roses will, immediately they are plucked, be transferred to the macerating jars. where, thanks to this procedure, they will deposit their perfume in all its freshness and delicacy. Only the quantity of leaves required at the its freshness and delicacy. Only the quantity of leaves required at the moment will be collected, a few minutes sufficing to transfer the leaves from the plants to the machines." "Commerce" of the 26th July adds: "This expedition is favourably contrasted with the procedure followed in Turkey and in France, where frequently the Roses plucked in the morning are only distilled in the evening. As to the oil of Roses produced in Saxony during last year, it is claimed that not only did it not fall short on comparison with the Turkish product, but that it was better than its rival in delicacy and strength, and the lasting character of its perfume."—("Kew Bulletin.")

A MELON NOVELTY.

ENCLOSED herewith you will find a seedling Melon plant, respecting which I shall be glad to have information. Three days ago I sent to table a very fine looking Melon Prince Arthur; when it was cut, the seeds inside were found to be germinating, and showing various stages of plant development. The plant sent was the most advanced, the stem 2 inches long, and the cotyledons well formed. What appears to be the most remarkable in connection with this matter is the chlorophyll in the leaves. How did this get there? Is it possible that sufficient light could penetrate the skin and flesh of the fruit to produce it? The skin of this Melon was particularly thin, and the flesh very transparent. Would the unusual hot sun which we have had account for the seeds germinating inside the fruit? I have frequently seen split Melons with young plants growing out of them, but this Melon was perfectly sound, very smooth, and of handsome appearance. It had been cut from the plant, and placed in a cool vinery three days previous to being sent to table. Any information respecting it will be acceptable to both my employer and myself.—Thos. Arnold, The Gardens, Cirencester House.

[The Melon plant received had a stem 2 inches long, with roots in formation and well developed cotyledons of a pale green colour. Our correspondent is no doubt right in his conjecture. The requisite conditions for germination were present—namely, heat, moisture, and oxygen gas, this being an essential constituent of water, while sufficient light from bright sun passed through the thin rind and transparent flesh for the deposition of chlorophyll in the cotyledons. The seedling was quite healthy, and would undoubtedly have grown satisfactorily if established in soil under suitable cultural conditions. Just as preparing for press a correspondent, "Muriel Grahame," informs us of a similar instance in a Lemon, green growths from the seed nearly half an inch long and roots of the same length when the fruit was cut open.]

HORTICULTURAL SHOWS.

THE last issue of the Journal of Horticulture, August 31st, contained a most interesting report of the Shrewsbury Horticultural Show (page 203), a report which I should like every individual connected with horticultural societies to read and inwardly digest. If societies and their secretaries generally would try and imitate the policy pursued by the Shrewsbury friends we should hear less of failure, and soon find a very different feeling to exist between societies and exhibitors.

In my opinion your correspondent in his report of Shrewsbury Show hit the nail on the head. If societies are to be successful they must not only gain the confidence and good wishes of the public, but must endeavour by every legitimate means in their power to retain their supporters. It frequently occurs to me that Show Committees are consumed with the idea that they are conferring a boon on the horticultural community by providing a Show, and that exhibitors ought to meekly submit, "and feel grateful" for the niggardly treatment so often meted out to them by many societies. If such societies find their entries and funds gradually declining year by year they certainly have nobody to blame but themselves. Show Committees would do well to bear in mind that they cannot very well get on without the aid of exhibitors if they would, who frequently travel many miles at great inconvenience and expense to contribute the shows.

Let societies offer the very best prizes they can, and there will be little difficulty in securing good entries and a show which a generous public will patronise and appreciate. It is a blind policy to extract the last fraction you can get from the pocket of the very men who make the show. Such niggardly treatment tends to drive exhibitors away in disgust never to return. I am pleased to know that there are societies which I could name, and that deserve all the praise that has been bestowed upon them from time to time, and which are to-day in a most prosperous condition. They have gained the confidence of the community in the first place by securing the services of the best judges they can obtain, and secondly by a liberal, generous, and considerate treatment of the exhibitors and supporters.—WM. INNES.

EVENTS OF THE WEEK.—During the ensuing week several important horticultural events will take place. The Committees of the Royal Horticultural Society will meet at the Drill Hall on Tuesday, September 12th; and on the 13th a special Show of autumn flowers and fruit will open at the Gardening and Forestry Exhibition, Earl's Court, continuing the following day. The Royal Caledonian Horticultural Society's Exhibition will be held at Edinburgh on the 13th and 14th inst. The show of Dahlias, Gladioli, and Early Chrysanthemums, which opened at the Royal Aquarium on the 6th inst., continues to-day (Thursday) and to-morrow.

- —— THE WEATHER IN LONDON. With the exception of a few slight local showers fine weather has again prevailed in the metropolis during the past week. The days have, as a rule, being bright and sunny but the nights rather cold. At the time of going to press it is fine and warm.
- ROYAL HORTICULTURAL SOCIETY.—The next meeting of the above Society will be held on Tuesday, September 12th, in the Drill Hall, James Street, Westminster. Mr. James Douglas will deliver a lecture on "Garden Phloxes and Pentstemons," and collections of these plants will be welcomed as a means of illustrating the lecture in a practical way. As the season for Gladioli is drawing to a close we have been requested by Messrs. Kelway & Son of Langport to say that their prize of a silver medal will be offered at this meeting for the best twelve Gladiolus gandavensis varieties raised from British seeds. Prizes are also offered by the Society for twelve distinct Gladioli grown by amateurs,
- —— MR. THOMAS MANNING.—After long, diligent, and faithful service as manager to the great firm of Messrs. James Veitch & Sons, Chelsea, Mr. Manning has well won the rest he will seek at the close of the present month. Few persons could possess more intimate and varied knowledge of plants and their value than Mr. Manning, and this combined with great business capacity made him a man of mark in the horticultural world. He has, "boy and man," been connected with the firm for forty-eight years. Mr. Manning will take with him wherever he may "settle down" the best wishes of a host of friends.
- We have received the first Fasciculus of that marvellous book the INDEX KEWENSIS, of which it may be said, as Linnæus and Haller said of John Ray's "Historia Plantarum," "opus immensi laboris." We have heard this described as a "Modern Steudel," and so it is in some respects; but it is that and something more, for it gives a citation of all the synonymes, with references to the pages of the works in which they are to be found, and this Steudel does not do. The title of the work is "Index Kewensis: an Enumeration of the Genera and Species of Flowering Plants from the time of Linnæus to the year 1885 inclusive, together with their authors' names, the works in which they were first published, their native countries, and their synonymes. Compiled at the expense of the late Charles Robert Darwin, under the direction of Joseph D. Hooker, by B. Daydon Jackson." It is a great work and worthy of Kew.
- MEDALS.—Now that medals are so freely provided as honours for commendable exhibits at horticultural and other shows we may appropriately refer to some artistic examples sent for inspection by Mr. J. Carter, 37, Howard Street, Birmingham, which he is now bringing before the public. The gold, silver-gilt, silver, and bronze medals are alike beautifully finished, while the various designs are highly artistic and appropriate to the objects represented so well.

- DEATH OF MR. GEORGE MARCHANT.—Though not a pushing man striving to keep his name before the public, Mr. Marchant occupied a very public position, to which he won his way by diligent work and honest endeavour. He was one of the Crimean heroes, receiving several wounds, also English and Turkish medals. He found employment in the London parks, and spent about thirty years of his life in them. For sixteen years he had charge of the Thames Embankment Gardens, first under Mr. Sinclair, then Mr. Cochrane, in the Metropolitan Board of Works days. On the County Council succeeding the Board, Mr. Marchant was sent to Ravenscourt Park, but soon returned to take full charge of the Thames Embankment Gardens. This position he held with much credit till his death, which occurred on the 28th ult. in his fifty-eighth year. A gentleman who has known Mr. Marchant and his work for years says of him, "A more conscientious worker could not be found. Faithful labour is always appreciated, and no man in the several parks was more highly thought of by his superior officer, Mr. Sexby, than was George Marchant."
- THE AGRICULTURAL HALL SHOW.—As most persons expected this speculation resulted in considerable loss—it is said upwards of £300. As might also be expected, the Council of the Royal Horticultural Society took care to secure a guarantee against bearing any share of possible loss occurring. We also learn that several trade exhibitors did little or no business to meet the considerable expense they incurred in sending large collections of produce. The Exhibition was a fine one, and it is regrettable that it did not receive a large share of public appreciation.
- DROUGHT IN FRANCE.—Mr. A. H. Pearson, writing from Angers on the 3rd inst., says:—"In passing down the boulevard here to-day I noticed several of the Chestnut trees which had gone to rest by reason of the drought, and subsequently pushed out new leaves and blossoms. One or two trees were quite white over. Is not this unusual? The pastures are in a fearful state, and the proverbial 'oldest inhabitant' never saw the Loire so low as at present." [There are numbers of leafless trees in the south of London, but France is ahead of us in having Chestnuts growing and flowering now as if in spring.]
- White Antirrhinums.—In reply to "A. D." (page 197) as to why I referred to this variety as "Iggulden's," I have to say that I believed him to be the first to introduce it to that part of the country, and I very naturally connected his name with it, not knowing any other that I could distinguish it by. It has been grown at Marston for some ten years, and I think I am correct in stating that it was in Mr. Iggulden's possession prior to that time. My only motive in writing the note (page 172) was to call attention to a very useful plant. If "A. D." had distributed the "splendid crimson" of which he writes, and I had fortunately shared in his liberality, I should certainly have spoken and written of it as "Dean's," without taking the trouble to ascertain whether or not he had a right to his name being coupled with it.—T. S.
- DROUGHT EFFECTS.—It seems almost incredible after the many fine rains that we have had in the London district, that trees should be suffering so severely from drought that at the end of August there may be seen at Strawberry Hill numerous Elms literally without a leaf on them, and this too in what is called the fertile valley of the Thames. I have rarely seen in relation to the effects of the season on trees greater contrast than was the other day found at Hackwood Park, Basingstoke, where on a solid chalk base trees and shrubs and grass were all luxuriantly beautiful, hardly a leaf having been shed. Then a few days later I looked in at Lady Freake's place, Fulwell Park, Twickenham, and there found the grass burnt brown, the trees shedding leaves wholesale, some being quite leafless, and sweeping literally going on constantly; in fact, it was just such a sight as may be looked for at the end of October; and yet the soil in this district has the reputation of being deep and retentive; but it is evident that when gravel at the base and trees are thick, the subsoil becomes so intensely dry that nothing short of a deluge of water such as a wet winter gives can fairly saturate the roots. Needless to say that this intense dryness of the soil extended to the kitchen gardens also, and rendered cultivation exceedingly difficult. It is a capital wet season position, but a very bad dry onc; and yet within 40 yards of the garden there is a small river full of water, but it might as well be in the moon so far as it affords any benefit to the trees or gardens. In all such situations the season has beyond measure demonstrated the immense need there is of an ample supply of water in dry weather, and here could a few thousands of gallons be lifted each day from the river it would be of the greatest value to the gardener.-A. D.

- NATIONAL AMATEUR GARDENERS' ASSOCIATION. The members of the above Association held their usual monthly meeting in the Memorial Hall, Farringdon Street, E.C., on the 5th inst., Mr. T. W. Sanders presiding. A lecture on "Begonias" was given by Mr. W. E. Jupp, a successful amateur grower, and a good discussion followed.
- THE TURPENTINE INDUSTRY.—Contrary to what most persons would infer, it is said on the authority of the United States Department of Agriculture, after careful tests, that tapping the Pine trees for turpentine is not injurious to the timber, and that the lumber is in no way affected by it. The turpentine industry, with a product worth 10,000,000 dollars annually, is thus a clear gain.
- Wood Wool.—In our report of the horticultural sundries exhibited at the Agricultural Hall Show last week we omitted to mention a superior kind of wood wool, which was noticeable in the excellent stand of Messrs. W. Wood & Sons of Wood Green, N. This wood wool, a sample of which is before us, is remarkably fine, and being sweet, soft, and clean, is well adapted for packing tender as well as firm fruit.
- THE TOTAL RAINFALL AT ABBOT'S LEIGH, HAYWARD'S HEATH, SUSSEX, for the past month was 0.55 inch, being 1.75 inch below the average. The heaviest fall was 0.23 inch on the 3rd. Rain fell on eight days. The highest temperature was 86° on the 17th, the lowest 43° on the 6th and 29th. Mean day temperature 75.20°, mean night temperature 53.12°, mean temperature 64.16°, which is 5.08° above the average. Where are our weather prophets who promised us a wet August?—R. I.
- NEW VIOLAS.—As so much has been written about Violas, I thought you might like to see blooms of the trio of large flowering rayless varieties I shall send out next year. The blooms sent are small, but they are larger when developed. The blue with a white centre is a cross between Ariel and Violetta, and named Pride of Etal. The white is Mrs. Scott, a seedling from Countess of Wharncliffe, crossed with Violetta. The yellow is George Lord, a seedling from Ardwell Gem crossed with Violetta. Princess May and Pure Love are miniatures; notice the Picotee edge in Pure Love. I have also a white Picotee edge, no rays at all, and so dwarf; and many fine varieties you shall see later on.—Geo. Steel. [The flowers of the first three varieties named are charming, although but medium sized. The "miniatures" are very small, but the colouring is delicate, and the Picotee edge just discernible in Pure Love.]
- ALTERATIONS IN EDINBURGH BOTANIC GARDENS. The Palm and temperate houses at the Royal Botanic Gardens, Edinburgh, have, we learn from a northern daily contemporary, just undergone reconstruction. The old Palm house was built in 1832, the newer or western half was erected in 1856. The former is octagonal in form, with a diameter of 60 feet; the latter is 100 feet long, 60 feet wide, and with an arched iron and glass roof 72 feet high. For the most part the specimen Palms and other tropical plants were placed in tubs, which had by no means an ornamental aspect. This arrangement Professor Bayley Balfour, Regius Keeper of the Garden, has now entirely abolished. The whole of the trees and plants in the temperate house and in the hotter Palm house are planted in specially prepared beds, and in consequence appear in this miniature tropical forest as if they were growing in their native habitat. The change has already told upon them in the most beneficial manner. The majority, indeed all of them, are showing signs of a vigorous life which has been unknown in the Palm house for Coils of pipes are placed along the side of the inner wall of the Palm house, and also along the iron gallery, so that in the winter an equable temperature of 50° may be maintained. The old Palm house was formerly heated from a number of small houses on the outside of the walls. These have now been cleared away, the lower walls have been opened up, and encircling the Palm house on all sides, save that by which it is joined up to the temperate house, is a handsome iron and glass annexe, which gives about 200 feet of staging, and imparts to the main building a lightness and beauty it never before possessed. Next year the range of greenhouses stretching from the herbarium to the Palm houses is to be overhauled, and the tank house may be taken up next. At this time an important re-arrangement of the heating appliances in the Garden has taken place. Formerly there were no fewer than twentytwo different furnaces and eighteen or nineteen separate stokeholes scattered all over the place. These have been concentrated into one stokehole, situated not far from the back of the Palm house. The total cost of the reconstruction of the Palm houses and the new heating arrangements has been about £3000.

- PRESENTATION AT ALDENHAM PARK GARDENS.—We understand that Mr. J. A. Cox, who for several years has served as foreman in the above gardens, was on September 1st presented with a marble clock, a set of carvers, and a dozen table knives and forks by his friends on the occasion of his leaving his situation.
- Wasps in Nottinghamshire.—Mr. J. Mallender, Hodsock Priory, Worksop, writes:—Wasp nests have been very numerous here this season. I have destroyed 115 nests within a mile radius of these gardens. I destroyed the nests in the daytime. It is an old plan, but after trying many new ways, I am most in favour of the method I have practised for more than thirty years. [Is the "old plan" a sccret?]
- ONION GUM.—A very convenient gum can be made of Onion juice. A good-sized Spanish Onion, after being boiled a short time, wil yield, on being pressed, quite a large quantity of very adhesive fluid. This, a correspondent remarks, is used quite extensively in various trades for pasting paper on tin or zinc, or even glass, and the tenacity with which it holds would surprise anyone on making the first attempt. It is the cheapest and best gum for such purposes, and answers just as well as many of the more costly and patent cements.
- THE WEATHER IN AUGUST.-Mr. W. H. Divers, Ketton Hall Gardens, Stamford, observes:—This was a very changeable month, but dry, and in this neighbourhood plant life suffered more from drought during the last week than in any previous time this year. We had twenty-one bright days. A heavy thunderstorm occurred on the 10th, and very hot weather on the 18th. The thermometer was 81° in shade at 9 A M., and registered 93° afterwards. We had a shock of earthquake at 6.41 P.M. on 4th. The barometer stood at 29.67 inches. Wind was in a westerly direction for twenty days. Total rainfall was 1.62 inch which fell on twelve days, and is 0.64 inch below the average for the month. The greatest daily fall was 0.43 inch on 11th. Barometer, highest 30:35 at 9 A.M. on 29th; lowest 29:58 at 9 A.M. on 21st. Highest shade temperature 93° on 18th; lowest 40° on 29th; lowest on grass 34° on 29th. Mean daily maximum 75.41°; mean daily minimum 53.54°; mean temperature of the month 64.32°. This is 3.92° above the average for the last ten years. The garden spring ran 15 gallons of water per minute on 31st.
- ZONAL PELARGONIUMS AT SWANLEY .- The utility and continuous beauty of these plants, both for planting in flower beds and for use in pots in the greenhouse, is recognised and admitted by everyone. Messrs. H. Cannell & Son have made a speciality of these plants, and in their hands rapid strides of improvement have been made. Enormous trusses are now produced in profusion, and the size of the individual pips would astonish most people who took the trouble to measure them. An ordinary watch is completely hidden if one of these pips is placed over it. Nothing of the beauty of the plant, be it understood, is lost from its size. Some flowers may with size become vulgar in the eyes of the fastidious, not so the Zonal Pelargonium. With it the term "vulgar" can never be named, they must always remain chaste and beautiful, the flower alike of the nobleman and the mechanic. I will mention a few of the singles which were in bloom on the occasion of a recent visit, and which I considered amongst the very best. Blue Peter, raised by that prince of Pelargonium raisers, Mr. W. B. Miller, is, though not a pure blue, unquestionably a decisive step in that direction; the flowers are medium in size, and possess a very marked bluish tinge which a clear white eye aids in emphasising. Albion stands pre-eminent amongst the pure whites, being a real improvement on Swanley Single White. Amongst the salmons Mascagni must be accorded a high place. In habit it is dwarf, bearing blooms of fair size with the utmost profusion, and of a soft silvery salmon shade with a white eye. It is certainly one of the most attractive in the collection. Mrs. French may be noted as throwing enormous trusses composed of shapely deep pink coloured pips. Miller's Favourite is a brilliant scarlet large-trussed variety, which is very striking. A very beautiful flower is found in Mademoiselle Trine. The habit of the plant is vigorous, and trusses are abundant, being composed of charming rosy magenta shaded pips. A bright scarlet worthy of special mention is found in W. P. Wright. The plant is dwarf and strong in habit, and carries its enormous trusses prominently above the foliage. It is a variety with a great future. Marquis of Dufferin is a grand magenta crimson coloured variety, with good sized pips. A distinct variety is Spotted Gem. The colour is a clear purplish pink, but the three lower petals are densely spotted with crimson. It is a very charming variety. Numerous other very beautiful varieties were in bloom, but those mentioned attracted my attention more especially.-H.

— THE "Kew Bulletin" for August, a copy of which has come to hand, contains as usual much useful information. Among other articles is a report of the "Californian Fruit Industries," and another on the "Plant Industries in the Caucasus." Other important matters dealt with include "Fibre Investigations in the United States," "Decades Kewenses, VI.," "St. Vincent Arrowroot," "Pulping Liberian Coffee," and "Henequen Hemp in Yucatan." Some miscellaneous notes are also given, and from these we extract the four paragraphs that follow.

LEITNERIA FLORIDANA, Chapm.—Dr. W. Trelease, Director of the Missouri Botanic Gardens, St. Louis, U.S.A., has forwarded to Kew a specimen of this species, found by him in Missouri. This interesting plant, previously recorded from the salt marshes of Florida only, was placed by its author in the order Myricaceæ, but raised to the rank of a monotypic order by Bentham and Hooker in the "Genera Plantarum," vol. iii., p. 396. A good figure of it is given in Hooker's "Icones Plantarum," t. 1044. It forms a shrub from 2 to 6 feet high, somewhat resembling a Willow, from which it differs in having a solitary ovule affixed laterally. From Myrica it is easily distinguished by the absence of resinous glands in the leaves, while the elongated (not globose) inflorescence separates it from Platanus.

WOOD OF ARAUCARIA.—The trank of the historic Araucaria imbricata, referred to in the "Kew Bulletin" for January last, p. 24, as having died during the previous autumn, has been cut up and a specimen deposited in the Museum. The trunk measures about 30 feet high and 1 foot 4 inches in diameter at the base. A sample of the wood of a tree of this species grown at Tortworth Court, Gloucestershire, and a walking stick made of the same wood, both presented by Earl of Ducie, F.R.S., in 1890, are shown in Museum No. 1. The wood is light, soft, and open grained, and apparently of but little value economically, though in its native country it is said to be strong and durable. The best known timber-producing species of Araucaria, however, are the Moreton Bay Pine (A. Cunninghami, Ait.) and the Bunya Bunya (A. Bidwilli, Hook). The first is a native of Northern New South Wales and Queensland, and the second grows only in Queensland. Both are trees of some 100 to 150 feet high, producing planks of very large size and light-coloured even-grained woods, suitable for furniture, flooring, and other carpentry work; some samples of the Moreton Bay Pine are prettily marked with small pale clouded knots, somewhat resembling Birds'-eye Maple. It takes a good polish. Good specimens of both these woods are shown in Museum No. 3.

- FIJI FRUIT TRADE.—In a report just issued by the Colonial Office on the Fiji Island (No. 72, 1893), the following information is given respecting the fruit trade: —The trade of the colony has advanced rapidly during the year. The green fruit trade, however, has not increased to any great extent, and the profits made from the production and export of this staple have undoubtedly fallen off. This is owing, locally, to the presence of a disease among Bananas which prevents their bearing ("Kew Bulletin," 1890, p. 272; 1892, p. 48). The Government have for some time been endeavouring to arrange for the temporary services of a pathologist to examine the causes of this disease, and if possible to provide a remedy. The trade has also been affected by the competition of the Colony of Queensland in the markets of New South Wales and Victoria. The export of green fruit to New Zealand has, however, doubled within the last four years, as has also that to Victoria. There will always be a sale for Fijian green fruit, as the quality of the Bananas produced in Fiji is admittedly superior to that of those coming from Queensland, which are often sold under the name of Fijian Bananas. A few of the "Gros Michel" Bananas suckers have been imported from Trinidad, with the view of seeing whether they resist the disease better than the locally grown "China"

— Anthracnose in Vines.—The Vine disease known by the name of Anthracnose, caused by a minute fungus called Sphaceloma ampelinum, De Bary, is well known on the Continent and in North America. As a serious disease, its presence has only been noted in England during the past year, and it is probably widely diffused, specimens have been received at Kew for determination from such distant localities as Dorking and Edinburgh. Anthracnose is an insidious disease, which in its milder forms would not be likely to arouse apprehension on the part of the cultivator, yet successive attacks for four or five years often kill the plant. The young shoots, leaves, flowers, and fruit are attacked. The disease on the young shoots appears at first under the form of minute brown spots. These soon increase in size and become sunk or depressed at the centre, the epidermis becomes broken up into minute white downy particles, and as the disease extends the

shoots become almost black, the internodes are short, and the development of the leaves arrested, not expanding, of a harsh, brittle texture, and hairy below. The present disease is quite distinct from the one known as "black rot," although the two have by some authoritics been considered to be identical. The following method of treatment has generally proved effectual in eradicating the disease: -In the spring, before the buds open, the plants should be thoroughly sponged with a 50 per cent. solution of sulphate of iron in water; the atmosphere at this time should be kept damp. When the young shoots are about 6 inches long they should be dusted with flowers of sulphur, and if the disease makes headway the dusting should be repeated, the sulphur being mixed with an equal quantity of powdered lime. Very badly diseased plants should be removed and burnt, as such are not amenable to the above or any other mode of treatment. A detailed account of this disease, also preventive methods and treatment, is given by Viala. ("Les Maladies de la Vigne." Masson : Paris.)

— STOCKS FOR PEARS.—Mr. Spencer King writes from Ipswich:
—"In my little garden I am experimenting by budding Pears of good quality on stocks which have disappointed me. Bergamotte Esperen and Fondante d'Automne both on the Quince are most disappointing, although on the Pear stock in the same garden they do well. Amongst other kinds I budded Durondeau on the Bergamotte Esperen and Fondante d'Automne, and it bears very freely, and produces thus double grafted far larger crops than the remaining original stocks. Durondeau is a magnificent Pear. My original tree is on the Quince stock trained to a wall, but in that case I seldom get a crop, as frost cuts off the blossom."

THE WEATHER IN HERTFORDSHIRE.—Mr. E. Wallis, The Gardens, Hamels Park, Buntingford, Herts, writes:—The weather during August has been of a tropical character, and quite unprecedented for the amount of sunshine, rot one full dull day occurring during the whole month. Rain fell on ten days. Maximum in any twenty-four hours was 0.32, on the 23rd; minimum in any twenty-four hours was 0.01, on the 20th; total during the month 1.74, against 3.40 of 1892. Wasps have become a plague, and notwithstanding the destruction of 450 nests they are still masters of the situation, eating and ruining the fruit before it is ripe. I find nothing to equal cyanide of potassium for the destruction of their nests.

- FRUIT GROWING IN AUSTRALIA.—Although, says an Australasian contemporary, nearly every kind of fruit procurable in Europe is extensively grown in Australia, the two leading crops are Oranges and Grapes, both of which are acclimatised fruits, the Orange having been introduced about 1817, and the Grape about seven years later. The orangeries in the Ryde and Parramatta districts are equal, as regards the size of the trees and the luxuriance of the fruit, to any in Southern Europe. In Tasmania neither the Vine nor the Orange has been successfully cultivated, but in portions of Western Australia both appear destined to become leading crops. In Victoria various efforts have been made to cultivate the Orange, but without success. In estimating the rate of production, considerable difficulty is occasioned by the absence of uniformity in the statistical returns furnished by the different colonies, Grapes being, for instance, estimated by the ton in one and by the pound in another. This fact has long been a source of complaint, but at present nothing has been done towards placing the returns on a more uniform basis.

- APPLES AND COOL CHAMBERS,—A number of experiments that have been made by fruiterers of late seem to point to the fact that when shipments of Apples from Australia to London are found to be in bad condition on arriving at their destination, the cause must be attributed to something besides faulty packing. An Australian paper says that another important experiment recently made in Melbourne strongly supports this theory. A number of fruit merchants and others witnessed the opening of a case of Apples. A consignment of similar fruit, packed at the same time and in the same way, was dispatched to England by the steamer "Orient," and the Apples arrived in bad condition. On the case that was kept at home being opened the Apples were found to be in perfect condition, showing no sign whatever of decay, and possessing their full flavour and sweetness. They had been kept where the vcntilation was by no means perfect, but where the changes of temperature did not affect them in any way. The Apples which comprised the Five Crown, Sturmer, and Jonathan varieties were packed in an ordinary fruit case, each Apple being wrapped in tissue paper, and paper shavings being used for packing. Some Pears placed in the same case with the Apples were quite decayed, but they arc said to have been overripe when packed.

—— STEAM versus Hot Water Heating.—Much has been said about the preference displayed by the florists on the other side of the Atlantic for steam heating, but Archibald Lawson of Chestnut Hill is, says the "American Florist," changing his system of heating from steam to hot water. He says that as he only has about 4000 feet of glass it does not pay to have a night fireman, and as the old system does not require such close attention as steam he thinks it will be profitable to make the change.

PRIORY, WORKSOP, NOTTS, FOR AUGUST.—Mean temperature of month, 63 2°. Maximum on the 18th, 88.7°; minimum on the 6th, 41.3°. Maximum in the sun on the 8th, 135.1°; minimum on the grass on the 28th, 32.8°. Mean temperature of air at 9 A.M. 65.8°. Mean temperature of soil 1 foot deep, 62.2°. Sunshine, total duration, 199 hours, or 44 per cent. of possible duration. We had no sunless days. Total rainfall, 134 inch. Rain fell on thirteen days. Average velocity of wind, 7.6 miles per hour; velocity exceeded 400 miles on two days, and fell short of 100 miles on twelve days. Approximate averages for August:—Mean temperature, 59.7°; sunshine, 149 hours; rainfall, 2.36 inches. Very fine and warm month. The mean temperature is higher than in any of the previous seventeen years, and the maximum is higher than in any month since 1876. Of the previous Augusts only 1883 had less rain, and of the previous twelve only 1884 had more sunshine.—J. MALLENDER.

- PINKS ON THE RIVIERA.—From time immemorial perpetualflowering Pinks have been grown on the Riviera, as they are in Italy, and especially in Spain; but until the last twenty years they were only considered as household favourites, kept in pots on window-sills or in small gardens. Since the fast trains have been catablished, which carry the Riviera flowers to Paris in twenty hours and to London in less than two days, the cultivation of Pinks, both in the open air and under glass, has, according to M. de Vilmorin in a paper read at a meeting of the Royal Horticultural Society some time ago, made a wonderful progress. Acres and acres are now devoted to the growth of Pinks about Toulon, Hyères, Cannes, Antibes, Nice, and Beaulieu. Hundreds of glass houses, or temporary structures simply made of two rows of glass frames supported by wooden rails, give to the best class of winter-flowering Pinks the help of some additional heat and of some useful shelter. But acres upon acres are grown without any glass at all, straw mats or canvas screens only being used to protect the plants from the effects of radiation, and to afford them the necessary protection against the bad effect of rain or cold dew.

- CURIOSITIES IN CLASSING AND JUDGING .- I do not know whether a very useful book could be written on this subject, but at least a very amusing, as well as suggestive, one could. I have to thank an exhibitor for troubling my mind with the topic, but it seems all the same to have some attractions. At the recent Agricultural Hall Show there was a class for a collection of Sunflowers, "annual and perennial." Note the imperative conjunction! Continuing, the schedule said, ("Helianthus, Helenium, Harpalium, and Heliopsis only), to which Rudbeckias may be added." Did this addition present itself as a sort of afterthought to the framers, and is thus added? Even if it were, why not have included Rudbeckias into the select sorts in the parenthesis? But the real fun of the thing lies in the employment of the word "only" after Heliopsis, and then Rudbeckias are added. What a bull. So much for the class, now as to the judging. An exhibitor asked me how I should interpret the requirement in the schedule "annual and perennial," and I said as an imperative requirement that both sections must be included. But the Judges actually, of the three collections staged, placed first one-admittedly a most beautiful one-that did not contain a single annual variety, whilst the second and third both fully complied with the requirements. We need a court of revision for prize schedules, and a court of appeal from improper judgments.—D.

— WILD FLOWER COMPETITIONS.—May I be allowed to endorse Mr. Alex. Dean's remarks (page 173) on this subject? I always consider it one of the most unsatisfactory classes in country shows. In many places we get over fifty entries for a bouquet of wild flowers. Now, I take it this idea of making a bouquet or bunch is intended to teach the children how to gather and arrange their flowers tastefully. I should like to know in how many cases this laudable object is attained. I venture to suggest about 5 per cent., the remainder are arranged by their parents, and very often by a gardening friend. This is successfully defeating the object in view. I often feel very sore on this point when judging, for I see all the prizes going to bouquets that have not been

made by the children. I think a little reformation in this matter should be made by the majority of committees when arranging their schedule for the next exhibition. It is a matter that can bereadily remedied. I am acquainted with one village where they have a very good method of arranging this matter. A rule is inserted in the schedule stating that the children's bouquets are to be arranged at the place of exhibition, under the supervision of a committeeman. Each child is allotted a space on the table, where there is ample room to work. Although only a village, I saw eighty of these little workers busily engaged on the morning of the show, the gentleman in charge of them sitting on the end of the table. I do not suggest this is the best method of securing a good display, for many of the bunches came out of the ordeal in a very primitive manner, while others clearly indicated they had been practising their work some time previously. At all events, the object of educating the children was attained. I cannot say my experience of committees is precisely the same as Mr. Dean's, for I know one place where ten first, ten second, and ten third prizes are awarded, making thirty in all; at another show the judges were told to place plenty of extra prizes on the children's exhibits. At a small village show, where the bouquets were somewhat numerous and the secretary the local squire, the judges were told to give prizes to all that were worth them. It is very rare one finds a class for a collection of wild flowers. Where such a class is given it should certainly be stipulated, and extra points would be allowed for the correct names of the plants staged.—JAS. B. RIDING.

CANKER IN PEAR TREES AS CAUSED BY MITES.

"M. SCHEUTEN'S account of his observations [of the Pear-leaf gall mite] was published in Wiegman's 'Archiv' for 1857, and translated into our own 'Annals and Magazine of Natural History' in the same year. The leaves of the Pear trees in his garden were attacked by black pustular inflated spots, under the epidermis of which he found the species of Phytoptus which he named Typhlodromus pyri. On examining a large number of spotted leaves in his garden, in which all the Pear trees were similarly attacked (one tree having a third of its leaves affected), he always found the same four-footed larvæ in the interior of the leaves, and, in most cases, on the exterior a species of eight-legged mite, which he took to be the perfect form of the Phytoptus. He gives figures of these, and from them it is plain that the so-called larva is a Phytoptus, and the supposed perfect form a Gamasus. These are here shown."—("Murray's Economic Entomology, Aptera," pages 340 and 341.)

Mr. Murray proceeds to discuss all the evidence for and against M. A. Scheuten's observations, and, reasoning from analogy, arrives at the conclusion that Phytoptidæ (gall mites) are invariably four-footed, and this has been accepted as authoritative by subsequent writers. But some leave a loop-hole—say, "the Phytopti, or gall mites, so far as known, have never more than two pairs of very short legs on the lower surface of the body in front." This is conclusive that little is known of the life history of gall mites from experience, except an occasional and distant observation. Such are practically worthless, for to prove anything the observations must be frequent and consecutive, embracing the annual cycle. From a cultural point of view this begins in spring or early summer, and as a gardener I prefer to commence a description of the Pear-leaf gall mite (Phytoptus pyri) from that time.

The mite lives on the small yellow shining young leaves, and causes red swollen places on the upper surface, which later on become dark red, and ultimately black. This is a common affection on the leaves of the Pear tree in this country, usually commencing at the end of May or early in June, but this year the attack began a month earlier. The spots are oval in form and of different sizes (A, fig. 32), a leaf natural size. On the under side of the leaf the spots are round at first, with a small depressed dot in the centre. This is shown in B, the under side of the leaf, natural size. Very often the blisters are close and run together, and are so numerous as to cover almost the whole surface. This, as almost every leaf on the tree may be attacked, greatly weakens the trees, and renders them unprofitable.

If a section be made through a gall, and it is examined with a lens, the cells in the middle of the leaf are seen, as at C, to be torn asunder, and in the middle of the blister, on its lower surface, is a small opening (a). This shows the condition of the gall while red, and there is neither erineum (hairs) nor mites or eggs in the interior or at its mouth, but the leaf hairs stand out from the leaf surface beyond the scope of the magnifying power for measurement. Not a mite is to be found on the affected leaf. Such is the state of affairs up to mid-July on the leaves first attacked, as well as those recently and still red. Where are the mites? Perhaps the answer may be found in the fact that while I was looking at some infested leaves overtopping a wood fence the owner of the garden suggested that the rain had washed them all away!

But the infection spreads from leaf to leaf, and shoot to shoot. Summer pruning is of no use in getting rid of mites, for they pass from the leaves first assailed to those of the young shoots springing from the axils of the attacked leaves. One such shoot is represented in D, the leaves being conspicuous by the bright red galls, and the central leaves

or growing point are galled all over. The mites also have galled the shoot at b; that is how and where canker in Pear trees caused by mites begins. Examine the galls as we may, and search every particle of leaf, not a mite is to be found. But the galls swell rapidly, assume a darker hue, and a section through a gall early in August reveals mites browsing in erineum and laying eggs. This is shown at c, in E, section through a developed gall; and examining a similar gall later, say early in September, we find the erineum gone, and the mites full fed, as shown at d. The mites go in and out by the opening, and may be seen on the leaf surface, only disturb the upper side of the gall. They are invisible to the naked eye, and only just made visible by a good pocket lens. Under a powerful microscope the mite is seen to have a lily-white body, two pairs of legs near the head, which has a pale flesh tint, and ends in a conical projection, containing the fine sword-shaped jaws and other mouth apparatus. This, shown in the figure at F, is less than 1-200 inch in length, and about 1-800 inch in breadth.

If examined microscopically later on in the summer only old mites are found in the galls. There are plenty of skins, and some long lumps, mite-like but shorter, without legs or bristles, and soon afterwards empty (and much shorter than the bodies of the mites) receptacles are

formation of the galls lurking in Pear-tree leaves in early summer? Why do they not deposit eggs in the first formed galls? What apparatus are they provided with to pierce through the lower cuticle of a leaf? and how can they deposit an egg in a hole four times less than its diameter? Why is a four-legged mite egg or bud never seen in a gall but where there are already the mites? On what do the four-legged mites subsist from the fall of until the appearance of the leaves in spring? The questions are the objections to the mites being always four-legged, and the only one met is that the mites live on the buds during the winter. If so, why are the mites never found in the buds?

2, Assuming the mite to be always four-footed, do the mites ever mate? Are not they strictly confined to parthenogenesis? Will parthenogenesis endure indefinitely?

3, Granted the mites pass the winter in the six or eight-legged state in the fallen leaves, how does it happen that if a tree is cut down or pollarded that the mites do not attack the leaves of the sprouts springing from the trunk?

4, If the mites are six or eight legged, why do they not deposit eggs in the holes first pierced? This, of course, tells against them, and is the grand secret, that is, they do, but they are not seen, for they are

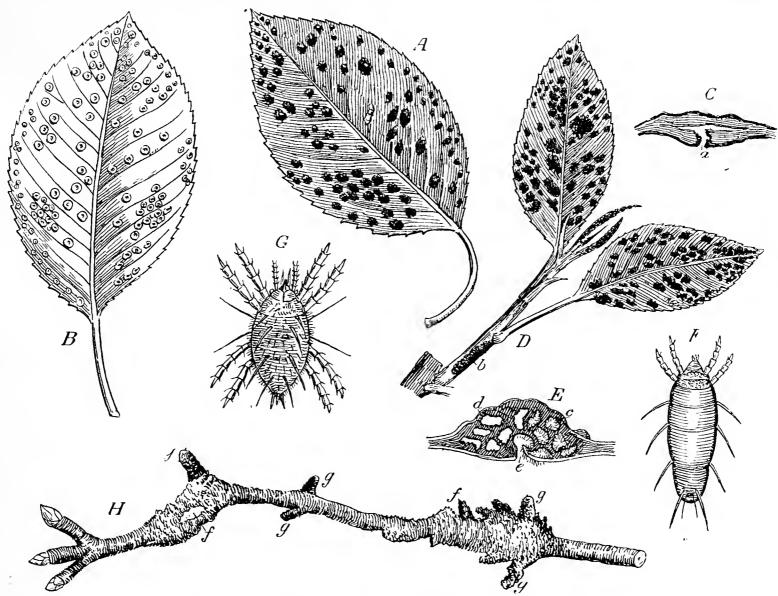

FIG. 32.—PEAR TREE LEAF GALL MITE CAUSING CANKER.

found in the galls. Do not get alarmed if cut off legs as large almost as the fingers move up and down, for they are only the belongings of enemies to the mites, which they devour and clear out of the galls, except such as escape. If the section be rather a thick one, say one-sixteenth inch, it is possible that one of these creatures may be seen in perfect condition, and it is very unsightly. A four-legged mite can parade on a joint of one of its legs easily; but keep a steady gaze, then sooner or later an active creature with six or perhaps eight legs will flit over the section—in and out, everywhere in no time, so that it is difficult to get a good examination of these interesting creatures. The best way is to immerse the section of a gall in alcohol for about a minute, but the mite is very difficult to find after the emersion. The best I have yet been able to sketch is seen at G. This is the male; the female is larger, has also eight legs, the two hinder divided into two hair-like extremities, each for steadying her when depositing eggs, and in spring a long ovipositor, very singular and not depictable. These mites are the last occupants of the galls, except the animal that clears out the four-legged mites, and may be a Cheyletus. The six and eight-legged mites are seen on the leaf at the mouth of the galls, then they are found on the trees before the leaves fall, and they are seen on the trees in spring lurking in the cracks and crevices of the bark, their favourite haunts being the cankerous places their parthenogenetic progenitors have caused, as f in H. Now we have to face a few difficult questions.

caused, as f in H. Now we have to face a few difficult questions.

1, The mite (Phytoptus pyri) and all the sub-family Phytoptidæ are four-legged. Where are they from the fall of the leaf until the

enwrapped in the substance of the gall, and are not visible because

Concluding, H shows a twig of a Pear tree cankered by the Pear-leaf gall mite. It is distorted at f, and the spurs g have been killed by the parasites. Such trees can only be cured by killing the mites. There is nothing better for all mites than syringing the infested trees with a sulphur solution, for all Arachnoidea succumb to it. It may be made as follows: Slake 3 lbs. of quicklime in an iron copper, adding 2 lbs. of flowers of sulphur and 3 gallons of water, besides that used in slaking the lime. Mix and boil for a quarter of an hour, keeping stirred all the time. Allow the mixture to settle, and when cool pour off the clear liquid, place in stone bottles, and keep well corked in a dark place. Use a pint of the bisulphide of calcium, as the liquor is called, to 4 gallons of water, applying with a syringe or engine. It may be used in winter to kill the mites in the lurking places on the trees when the buds commence swelling, or as a preventive in spring when the shoots are about 2 inches long or the first leaves about half developed, using 1 pint to 12 gallons of water, repeating occasionally. At the strength first named it must only be employed over mature foliage, say in September.

The Apple tree gall mite (Phytoptus mali) is similar to P. pyri in its effects on Apple trees in producing canker, but differs in several essential points entomologically, especially in the gall formation, which is the only part about mites which has been well worked out.—

G. ABBEY.

CHRYSANTHEMUMS IN THE PARKS.

CHRYSANTHEMUMS are somewhat extensively used for bedding purposes in many of the public parks in London, and with good effect. At Regent's Park I recently noticed several beds filled with the early flowering varieties, and these on a dull day are very striking at this time of the year. In Hyde Park, too, summer Chrysanthemums form a feature, and are usually much admired, the same applying to those in other public places around the metropolis.—C.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday evening at Anderton's Hotel. Fleet Street, Mr. Harman Payne occupying the chair. The minutes of the meeting of April 12th, and of the special meeting of July 21st, were read and confirmed, after which the Chairman read a suggestion from New Zealand that inasmuch as certain colonial growers were of opinion that their cultivation of Japanese varieties was little, if at all, behind the home growers, the N.C.S. should offer a medal or other prize open to all growers or societies in the Australian Colonies, these exhibits to be sent over at the exhibitor's expense, and staged at one of the Society's exhibitions. It was resolved that the matter be referred to the Schedule Sub-Committee. The Gosport, Crediton, and Tenby societies withdrew from affiliation. The Secretary announced that the receipts up to the present amounted to more than £150, and that the promises to the reserve fund had nearly all been fulfilled. An election of a member to the Floral Committee in place of Mr. E. Sanderson, deceased, was then proceeded with, resulting in the appointment of Mr. Edwin Molyneux by a substantial majority. The unsuccessful candidates were Mr. D. B. Crane and Mr. Witty.

Mr. Pearson of Chilwell and Mr. Shea being desirous of laying their

Mr. Pearson of Chilwell and Mr. Shea being desirous of laying their views before the Committee in regard to certain matters concerning the working of the Society, it was, after some discussion, resolved that the former be invited to attend one of the meetings in October, and the latter a meeting in December to do so. Eleven new members were elected, and the Port Elizabeth Chrysanthemum Society (Cape of Good Hope) received in affiliation. A vote of condolence to one of the Society's Vice-Presidents, Sir John D. Llewelyn, was passed on the

occasion of the melancholy fatal accident to his son.

COMMENTS AND OBSERVATIONS.

Some weeks ago a writer in this Journal remarked that a note-book was "a record of impressions which pass away as rapidly as they come, leaving behind them nothing but a memory." Such is not exactly the case, for "impressions" occasionally leave something more than "a memory;" but it frequently happens, as your correspondent observed, that many useful hints are hidden away between the pages of a note-book, long forgotten it may be by the owner. There are exceptions, but these only go to prove the rule, and how much important matter is thus kept hermetically sealed from the world it would be difficult to say. One thing, however, is certain, and that is if readers were to turn over the pages of their records, sifting the corn from the chaff, and let the bright light of publicity shine upon anything that might be useful to the gardening community, they would be benefactors.

In this matter I am not altogether blameless, for it is my custom to fill many note-books. Some of my observations are recorded for the benefit of the public, others sink into oblivion. For the purpose of adding to my store I, in common with others interested in horticulture, wended my way to the great Show held under the auspices of the Royal Horticultural Society at the Agricultural Hall last week, and there made a few notes, but observed more. Some of my impressions, I concluded, would be worth "putting into print," but after reading the detailed report of the Show which appeared in the Journal of Horticulture last week, second thoughts suggested themselves, and the old German proverb, "Speech is silver and silence is gold," came uppermost in my mind. However, the pleasure of writing conquered, and there can be no harm in referring to a few points that to me were specially interesting.

The first question that suggested itself to me was, Is the Show a success? From an artistic point of view it undoubtedly was, for, not even excepting the display in the Temple Gardens, it was one of the finest fruit, flower, and vegetable exhibitions ever seen in London. The exhibits as a whole were of a high-class character, and the arranging of them perfect. There were, it is true, one or two hitches in regard to the staging, but these were alluded to last week, so let them pass. Yes, the Council of the R.H.S. did their part well so far as getting together a magnificent collection of garden produce was concerned; but were their efforts appreciated? In other words, was the Show financially speaking a success? Judging by the number of visitors present on most days a negative reply might safely be given. On the opening day

the attendance was decidedly poor, and on Thursday afternoon—from 3 o'clock to 7 in the evening—it was miserably thin. There were on the latter occasion perhaps not more than 200 people—truly a sorry number for such a grand Show. It is reported that only £40 were taken at the barriers on the opening day. How does this compare with £535 taken at Shrewsbury on their opening day, and on a subsequent day £1400?

Some persons present were puzzled to know why the exhibition was so poorly attended, and were busily suggesting various causes. "The Show has not been advertised enough," mournfully observed a standholder, who parenthetically informed me that he had paid a sovereign per foot of floor for his stall; but a champion of the Agricultural Hall Company close by remarked that it was the people who did not respond. That is so, and as we all knew it was the true cause of the thin attendance. The Agricultural Hall is a grand place in which to hold a large flower show, but for this purpose the hall itself is in the wrong position. Everyone who knows the north-east of London as well as I do will agree with me that flower shows are not consistent with the tastes of the inhabitants of "Merrie Islington." The Islingtonians will flock in thousands to see a Military Tournament or a "World's Fair" with all its monstrosities; but they will not pay a shilling or sixpence to see a magnificent display of fruit, flowers and vegetables. That I predicted long ago, and, now it is too late, perhaps those responsible for the affair will agree with me. Had it been possible to have induced a member of the Royal Family or some other notability to open the exhibition formally, it might have proved some impetus to the attendance, but as it is from that point of view a failure must be recorded.

At the risk of being set down as an incurable pessimist there is another point to which I should like to refer—namely, the difficulty exhibitors had to obtain passes. Whether this was so in every case I am not prepared to say, but a report reaches me that a representative of one of the largest exhibitors had some trouble in this respect. More than one unlucky attendant with exhibits had to remain in the hall the whole day, for his ticket only permitted him to enter once. Surely this is short-sighted policy on someone's behalf, and can do no good. I could not ascertain what arrangements were made between the R.H.S. and the Agricultural Hall Company, and am therefore at a loss to know whom to blame. That matters but little, however, for the error is equally as apparent, and should not have been committed.

But while pointing out these little failings one must not forget the many good things that were observable. As already mentioned, it was a grand show, and worthy of a better attendance. Fruit formed a notable feature, the long tables of gigantic Apples of perfect shape and colouring reminded one of the splendid exhibition in the Guildhall a few years ago. The Apples, Pears, Plums, and Peaches exhibited by Messrs. T. Rivers & Son were magnificent, and had such a splendidly finished appearance about them as to "make one's mouth water." Growers no doubt made a note of the valuable Monarch Plum, which was conspicuous in this exhibit, as being one of the best late varieties in cultivation. Messrs. Bunyard, Veitch, Cheal, and Paul likewise, in putting forth their best efforts, gave visitors a proof of what they are capable of doing in growing fruit. The majority of the Apples staged were remarkable for their colouring; in a few cases the fruits were as rich-looking as Pineapple Nectarines. Some of the Apples were not quite so large as I have seen them, perhaps owing to the prolonged drought, but Mr. Woodward, Barham Court Gardens, Maidstone, staged a fruit of Peasgood's Nonesuch which, according to a notice on the exhibition card, weighed 23 ozs.

Grapes were beautifully coloured, and as a whole shown in splendid condition. This was the general verdict of many experts present. One curious fact, however, appeared to have escaped the notice of many observers, and it may be worth recording. As reported in your last issue, Mr. S. T. Wright, gardener to C. Lee Campbell, Esq., Glewstone Court, Ross, exhibited some magnificent 6 lb. bunches of Black Alicante Grapes, which for perfect finish could not be excelled. So far so good, and, as they should be, the Grapes were much admired. But when visitors read printed in bold type on a placard placed in front of the Grapes, "These Vines were winter-dressed with 'Killmright,' 4 ozs. to the gallon," it appears as if something was wrong. "Would it not have been better to have substituted 'Feedmright' for 'Killmright?'" sensibly remarked a bystander. Perhaps it would, for if Mr. Wright had dressed his Vines with the "Killmright" insecticide, it was obvious that he had also "fed 'em right!"

In glancing over the numerous cut flowers one class in the competitive section struck me as being somewhat out of the common. I refer to "a collection of Dahlias arranged for effect." There were two exhibitors in this class—Messrs. J. Cheal & Sons and Messrs. Keynes, Williams and Co. As already reported, the first-mentioned firm secured the premier award for a really meritorious exhibit. The Dahlias comprising the various sections were arranged in sprays, and being fresh and clean on the opening day made an imposing display. But was it not a little out of place to use Maidenhair Ferns and small Palms in pots among these flowers? Asparagus sprays were also employed which would pass muster, these being grown out of doors, as the flowers were; but I cannot help thinking that the Palms and Ferns looked a little ambiguous. True, nothing definite was stated in the schedule, and under these circumstances exhibitors were at liberty to use what they

like. This is written impartially, my object being to discourage the use of stove plants with outdoor flowers rather than that of fault-finding; for, as before said, Messrs. Cheal & Sons' Dahlias were deserving of the honour bestowed upon them.

Those persons who went to the Show for the purpose of seeing the Orchids, as some did, must have been disappointed, for these were not well represented. There was but one small group arranged on a table, and the few visitors present made a close inspection of them. The plants were from the rich stores of Messrs. F. Sander & Co. of St. Albans and Messrs. W. L. Lewis & Co. of Southgate, and comprised some choice species. A hybrid Cypripedium named C. Sander-superbiens, shown by that well-known amateur grower, Mr. Norman N. Cookson of Wylam-on-Tyne, Northumberland, struck me as being exceptionally beautiful. This Cypripedium, moreover, is interesting from the fact that it is the first Sanderianum hybrid yet produced. Mr. T. Statter of Stand Hall, Manchester, I noticed, also had a good hybrid under the name of Cypripedium Edwardi, the result of a cross between C. Farrieanum and C. Veitchi.

Agaves, like most succulents, are not everybody's plants, but the seedling exhibited as A. Leopold II. by W. B. Kellock, Esq., of Stamford Hill, appeared to attract more than ordinary attention. It is, as you remarked last week, "a magnificent plant with an interesting history," the details of which the raiser was good enough to describe to me as well as to others. The gist of the matter being given, however, on page 195 of last week's issue of the Journal it is needless to reiterate here. It occurred to me, though, that a great amount of patience is needed in hybridising Agaves and raising them from seed. Fifteen years it has taken to produce the plant which gained a first-class certificate, and obviously it has had every attention. Mr. Kellock informed me that he had another plant of a similar kind and from the same sowing at his home, and which he thought was the better of the two. Experts, including Mr. T. Baines, have also expressed the same opinion. When will Mr. Kellock bring it before the eyes of an admiring public?

So far as I could see your lengthy report appeared accurate in the main, but no mention is made of the two specimens of Dracæna lineata shown by Messrs. B. S. Williams, and for which a silver Banksian medal was recommended. A similar honour was adjudged the same firm for four specimen Tree Ferns of a particularly healthy appearance. Whilst on this subject it may not be out of place to ask whether an award was made to Mr. W. Cooper for the large number of greenhouses and heating appliances? No mention of such appears in any report that I have perused, and upon asking an R.H.S. official I was informed that "they had nothing to do with that division."

The competition in the plant and cut flower classes was not so keen as might have been expected. It was noticeable that in some instances there was only one exhibitor, and in others none were forthcoming. What was the cause of this? Where were our leading Begonia growers? A class for a group of Tuberous Begonias arranged with foliage plants was provided, and good prizes offered—namely, £7, £5, and £3, but not a single exhibitor was forthcoming. The same occurred in the classes for groups of Cannas, Liliums, Early Chrysanthemums, and Asters, whilst of Zonal and Ivy-leaved Pelargoniums none were shown other than in miscellaneous collections. These would have added interest to what everyone must admit was really a grand exhibition, and moreover, imparted a brightness amongst the rather dull groups of plants.

One more note and I have done with my observations this week. Who did not notice the beautiful Exacum macranthum shown by Sir Trevor Lawrence, Bart., and for which a first-class certificate was awarded? That it deserved this distinction no one can doubt, but it seems curious no one has hitherto exhibited a plant of it before the R.H.S. Perhaps it has been shown; then why not certificated ere this? It is by no means a new plant, having been figured some time ago in these pages, and I believe it was introduced from Ceylon in 1853. Better late than never.—Observer.

NATIONAL DAHLIA SOCIETY.

SHOW AT THE CRYSTAL PALACE.—SEPT. 1ST AND 2ND.

THE combined effects of the weather and the great Show at the Agricultural Hall thinned the Exhibition of the National Dahlia Society somewhat, the tabling being in excess of the demands upon it. The Islington fixture doubtless kept a number of miscellaneous exhibits away, but notwithstanding this there was an excellent display. The drought has told against the blooms somewhat, yet the majority were in excellent character. Mr. John Walker came out in splendid style, scoring a sequence of victories in the smaller classes. Why does he not throw down the gauntlet in the largest ones? The premier class brought some excellent stands, and Mr. Turner's victory was thoroughly deserved.

Novelties continue to pour in. On this occasion no less than eighteen certificates were awarded. We are not going to say that any one of the dozen and a half did not deserve to be honoured, but buyers will begin to despair of keeping pace with the new varieties if they continue to be turned out at this rate.

SHOW AND FANCY CLASSES.

The principal class was that for sixty blooms, Show and Faney intermixed, and there were three competitors. Mr. Turner won with

a very even and excellent collection. The flowers were not exceptionally large, but they were as neat, even, and fresh as could be wished. The back row blooms were George Gordon, Miss Cannell, Jas. Vick, Maud Fellowes, Imperial, John Walker, Clara, John Hickling, W. Keith, Seraph, Jas. O'Brien (Fancy), Wm. Rawlings, Rev. J. B. M. Camm, Gloire de Lyon, Hy. Walton, Professor Fawcett (self), a yellow, rose-tipped seedling, Jas. O'Brien (self), Duchess of Albany, and a crimson seedling. Middle row: R. T. Rawlings, Hugh Austin, Wm. Powell, John Standish, Professor Fawcett (Fancy), Matthew Campbell, Geo. Rawlings, Grand Sultan, Comedian, Agnes, Shirley Hibberd, Primrose Dame, Mr. W. Slack, Crimson King, Julia Wyatt, Richard Dean, Mrs. Langtry, John Bennett, Burgundy, and Alice Emily. Front row: Willie Garrett, Purple Prince, Sunbeam, Dazzle, Mrs. Gladstone, Ruby Gem, John Keynes, a buff seedling; Herbert Turner, Mr. Harris, Mrs. S. Hibberd, Nellie Cramond, Flag of Trucc, Comedian, Diadem, Goldfinder, a seedling, Kathleen, Mrs. Hodson, and Colonist. A heavy and fine lot of flowers from Messrs. Keynes, Williams, & Co. secured the second prize, Arthur Ocock, T. W. Girdlestone, Eclipse, Richard Dean, Gloire de Lyon, Henry Bond, and Rebecca being a few of the best of them. Mr. M. V. Seale was third.

Messrs. Keynes, Williams & Co. did better with forty-eight, defeating the Slough grower in this class. Probably there were not many points between them in either case, and it was the better finish of the flowers which gave them the award. In their back row the Salisbury florists had Geo. Gordon, J. T. West, Miss Cannell, Colonist, Harry Keith, Jas. O'Brien, Henry Bond, Mrs. Glasscock, Dandy, Arthur Ocock, Gloire de Lyon, J. T. Girdlestone, Buffalo Bill, Dandy (sport), Jas. O'Brien and Rebecca (sport). The first named was a splendid bloom. In the middle row they had Mrs. Gladstone, Mrs. Foreman, R. Dean, Mrs. Stancombe, Mrs. J. Downie (sport), Thos. Hobbs, Mrs. Langtry, Wm. Powell, Thos. Goodwin, Gaiety, Jas. Cocker, Duchess of Albany, Rev. J. B. M. Camm, Wm. Rawlings, Peacock and Majestic. In the front row were John Hickling, Joseph Ashby, T. J. Saltmarsh, Nellie Cramond, Robina, Harrison Weir, Willie Garrett, Wm. Jackson, M. Campbell (sport), Ethel Britton, Crimson Globe, Frank Pearce, Mr. Harris, Mrs. W. Slack, a crimson seedling; and Hy. Walton. Mr. Turner's best flowers were Geo. Gordon, Miss Cannell Shirley Hibberd, R. Dean, Crimson King and Wm. Keith. Mr. Scale was again the design of the control of Wm. Keith. Mr. Seale was again third, showing, as before, much smaller flowers than his rivals. There were five stands of thirty-six, and that from Mr. John Walker, which was first, was without doubt one of the very best in the Show. The well known Thame grower has rarely put together so heavy, even and well-finished a collection. His back row flowers, Seraph, Prince Bismarck, Majestic, Crimson King, J. T. West, Harry Keith, Mrs. D. Saunders, W. Rawlings, Hercules, Arthur Ocock, Maud, and Jas. Cocker were all splendid flowers, and most of the others were very good, notably T. J. Saltmarsh, Duke of Fife and Purple Prince. Mr. Humphries was second with a stand quite good enough to win in ordinary competition, but for all that he was well enough to win in ordinary competition, but for all that he was well beaten by Mr. Walker. He had no exceptional flowers, but all were fresh, even, well coloured, and finely finished. Mr. S. Mortimer was third with bears blooms and Mr. S. Mortimer was third with heavy blooms, and Messrs. Saltmarsh & Sons fourth. Mr. Walker won again with twenty-four, this time defeating four strong opponents. He had a splendid stand, though relatively hardly so good as his other. W. Rawlings, Gco. Rawlings, T. J. Saltmarsh and A. Rawlings were four of the best examples. Mr. Humphries was second with smaller but good flowers, Messrs. Saltmarsh, & Son third and Mr. Mortimer fourth. The best stand of twelve came from Mr. A. Rawlings, who had W. Rawlings, J. T. West, Geo. Rawlings, Rev. J. B. M. Camm, Maud Fellowes, Willie Garrett, Mrs. Langtry, Harry Keith, Mr. Glasscock, R. T. Rawlings, Professor Fawcett (self) and Mrs. Gladstone in excellent order. Mr. H. Harris was second with much smaller blooms, but even and fresh, Messrs. Cheal & Son third, and Mr. Tranter fourth.

The amateurs came out bravely in the class for twenty-four, no less than six competing. Mr. West, gardener to W. Keith, Esq., Cornwalls, Brentwood, was as usual to the fore, and he was placed first for a very fine stand, the flowers being well developed, clean, fresh, and excellently finished. The back row flowers were Willie Garrett (very good), Mrs. Gladstone, W. Keith, J. T. West, G. Rawlings, Maud Fellowes, John Standish (very fine), and Majestic. Middle row: Matthew Campbell, Harry Keith, Frank Pearce, Arthur Rawlings, John Britton, W. Rawlings, Clara, and Sunbeam. Front row: Victor, Wm. Powell, E. Shecrman, John Walker, Shirley Hibberd, Ethel Britton, Hy. Glasscock, and J. C. Vaughan. Mr. Arthur Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, also had an excellent stand, though his flowers were hardly so smooth and well finished as Mr. West's. He was placed second, and his best examples were Geo. Rawlings, Mr. Glasscock, Arthur Ocock, and the Rev. J. B. M. Camm. Mr. Thos. Hobbs, Easton, Bristol, was third with very neat flowers; and Mr. W. Mist, Collingwood, Ightham, fourth. Six also competed with twelve blooms, the first prize going to Mr. Vagg, gardener to J. Theobald, Esq., M.P., Havering, Romford, who had excellent examples of Geo. Rawlings, Maud Fellowes, W. Rawlings, Arthur Ocock, J. Rawlings, Duke of Fife, Mrs. W. Slack, T. J. Saltmarsh, W. Garrett, R. T. Rawlings, Prince of Denmark, and Mrs. Gladstone. Mr. T. Anstiss, Brill, Bucks, was a very good second; Mr. Hopkins, New Passage, Bristol, third; and Mr. S. Cooper, Hamlet, Chippenham, fourth. Mr. G. Boothroyd, 17, Orchard Place, Chichester, had fair flowers of Jas. Cocker, Duke of Fife, Ethel Britton, John Walker, Mrs. Gladstone, and W. Rawlings in the class for six, and won from Messrs. Whceler, 53, Bell Street, Henley-on-Thames; J. Gilbert, Brooklands, Freshwater, Isle of Wight; and J. Cousens, Langley Burrell.

The single variety classes were about the average as to quantity and quality. The best six of any dark variety came from Mr. J. Walker, who had Prince of Denmark in beautiful order. Messrs. Keynes, Williams & Co. were second with Niobe, and Mr. Humphries third with Wm. Rawlings. There were nine stands in all. Mr. West showed Mrs. Gladstone finely in the light class, and was placed first, Mr. Humphries being second, and Messrs. Saltmarsh third with the same variety, one other competing. Mr. Walker had a good stand of yellows, being easily first with a splendid box of John Hickling. Mr. Humphries was second with R. T. Rawlings; and Mr. Mortimer third with John Hickling; two others competed. There were only two stands of tipped flowers, Mr. Mortimer being first with Mrs. N. Halls, and Mr. Seale second with Mrs. Saunders. A neat box of Frank Pearce secured Mr. Humphries the first prize for striped varieties. Mr. Walker was second with Matthew Campbell, and Mr. Seale third with Hy. Eckford. Mr. Turner had a lovely box of Miss Cannell in the class for edged flowers, and was placed first. Mr. West was second with J. T. West, and Mr. J. R. Tranter third with Florence Tranter. There were four other boxes. Mr. Mortimer had the best six of John Walker, Messrs. Humphries and Such following; six competed.

CACTUS AND DECORATIVE.

There were three very good stands of eighteen Cactus and decorative varieties, the flowers being very good all through. Messrs. Cheal and Sons were placed first, having the following varieties in very fine condition—Beauty of Arundel, St. Catherine, Black Prince, Professor Baldwin, Honoria, Duke of Clarence, Mr. Tait, Christine Cheal, Ernest Cheal, Delicata, Lancelot, Countess of Radnor, Sir Roger, Josephine, Countess of Gosford, Bertha Mawley, Duchess of York, and Robert Cannell. Messrs. Keynes, Williams & Co. were second with a fresh, well-coloured stand, in which Apollo, Countess of Pembroke, Dawn, and Lady Penzance were conspicuously good. Mr. Chas. Turner was third. There were six stands of twelve, and they made a brilliant display. The best of them was that from Mr. Geo. Humphries, who had Juarezi, Amphion, Sidney Hollings. Duke of Clarence, Bertha Mawley, Baron Schröder, St. Catherine, Robert Cannell, May Pictor, Kynerith, Countess of Radnor, and Professor Baldwin, in splendid order, the flowers being fine and admirably coloured. Messrs. Paul & Son, the Old Nurseries, Cheshunt, were a good second, but their flowers were somewhat lumpily arranged, and would have shown to much greater advantage if they had been better displayed. Mr. J. Stredwick was third with a very neat stand, and Mr. E. F. Such fourth. Messrs. Keynes, Williams and Co. won from two competitors with twelve true Cactus varieties, and their stand was a delightful one. It was composed of a fine crimson seedling named Gloriosa, albeit with a leaning to the decorative group, Kaiserin, Duke of Clarence, Countess of Radnor, Miss Violet Morgan, Robert Cannell, Delicata, Apollo, Bertha Mawley, Countess of Gosford, Chancellor, and Lady Penzance. Messrs. Cheal & Sons were second with Robert Cannell, Delicata, and Professor Baldwin very good, and Mr. M. V. Seale a close third.

In the amateurs' class for twelve varieties of Cactus, six blooms each, Mr. J. West was placed first for splendid flowers of Joseph Chamber-lain, Glory of Brentwood, Blanche Keith, Duke of Clarence, Charles Rolfe, Marchioness of Bute, Bertha Mawley, Mrs. Keith, and four promising seedlings. Mr. Stredwick received the second prize with six varieties, three blooms of each: there were eight competitors. Edward Mawley, Esq., was awarded the first prize in another class for large and bright blooms of Duke of Clarence, Bertha Mawley, St. Catherine, Juarezi, Delicata, and Professor Baldwin. Mr. W. Hopkins, New Passage, near Bristol. took the second prize, and Messrs. Cooper and Fowler the third and fourth.

Pompons. For twenty-four varieties in bunches of ten blooms each, Messrs. J. Cheal & Sons were deservedly awarded the first prize for well formed flowers of Boule d'Or, Grace, E. F. Jungker, Darkness, Ringdove, George Brinckman, Arthur West, Fairy Tales, Admiration, Lady Blanche, Sun-Brinckman, Arthur West, Fairy Tales, Admiration, Lady Dianche, Bunshine, Rosalie, Martial, Tommy Keith, Marion, Isabel, Favourite, Whisper, Eurydice, Iolanthe, Eva Goldfinch, Phœbe, and Cecil. Mr. Charles Turner was a good second, Little Lady, Captain Boyton, Isabel, Irene, and Janet being particularly prominent in his stand. Messrs. Keynes, Williams & Co. were placed third, and an extra prize was awarded to Mr. M. V. Seale, both staging excellent examples. With twelve varieties in bunches of ten blooms each three competed, the premier award falling to Mr. George Humphries for a most even and brilliant stand, consisting of Little Duchess, Darkness, George Brinckman, Arthur West, E. F. Jungker, Red Indian, Mabel, Lilian, Phœbe, Lorna Doone, and Whisper. Messrs. Paul & Son, Cheshunt, received the second award, Mars, Lady Jane, and Red Indian being the most prominent. Mr. E. F. Such was placed third for a very fair collection.

In the amateurs' class for six varieties of Pompons in bunches of ten blooms each, there were three collections staged. Mr. J. T. West received first honours for Arthur West, Mary Kirk, a seedling (brilliant red), Winifred, Eva, and Tommy Keith. Messrs. J. Stredwick, Silver Hill, St. Leonard's on Sea, and Mr. William Mist, Sevenoaks, received the other awards in the order of their names. In the class for a similar number of varieties, but six instead of ten blooms to form a bunch, there were again only three exhibits, the prizes falling to Mrs. S. Cooper, Hamlet, Chippenham, Mr. C. Osman, South Metropolitan District Schools, and Mr. W. C. Pagram, Weybridge, Surrey, who were placed first, second, and third respectively.

SINGLES.

The singles made, as they invariably do, a very attractive feature. In the nurserymen's class for twenty-four varieties, twelve blooms each

there were only two collections staged, these coming from Messrs. Cheal & Sons and Mr. M. V. Seale. They ran each other very close for premier honours, which were finally awarded to the first named firm, who staged bright and fine blooms of Evelyn, Lowfield Beauty, The Bride, Yellow Satin, Miss Linnaker, James Scobie, Annie Hughes, Duchess of Fife, Gulielma, Amos Perry, W. C. Harvey, Eclipse, Kitty, Lady Whitehead, Miss Roberts, Cleopatra, Ruth, Miss Glasscock, Duchess of Anhault, Northern Star, Formosa, Duchess of Albany, Marion Hood, and Victoria. Mr. Seale's collection was well deserving of the second place, as the form in many varieties was most perfect; the varieties were Annie Hughes, Miss Henshaw, Huntsman, James Scobic, Amos Perry, Mrs. J. Coninck, Florrie Fisher, Alfonso, W. C. Harvey, Miss Linnaker, Lady Whitehead, Duchess of Westminster, Miss Jefferies, Duchess of Fife, Mrs. Gordon, Duchess of Albany, Alice Seale, Northern Star, Duchess of Anhault, Victoria, Cleopatra, Gulielma, and Miss Ramsbottom. There was a falling off in one or two bunches in the front, otherwise the collection might have taken higher honours. Three collections of twelve varieties were staged, and Mr. George Humphries was well ahead with the following collection-Florrie Fisher, James Scobie, Amos Perry, Mrs. W. C. Harvey, Gulielma, Cleopatra, Miss Henshaw, Eclipse, Miss Roberts, Miss Gordon, Duchess of Albany, and Duchess of Fife. Messrs. Paul & Son and Mr. E. F. Such took the other awards in the order of their names.

In Class 23, six varieties in bunches of ten blooms of each (amateurs), T. W. Girdlestone, Esq., was the only exhibitor, and received the first prize for Demon, Yellow Satin, Kitty, Ruth, Gris de lin, and Daisy. Mr. Mawley was the only exhibitor in the corresponding class for six blooms to form a bunch. He had Duke of York, Amos Perry, Rosebank Cardinal, Miss Roberts, Enchantment, and Yellow Satin, to which was awarded the first prize. With twelve varieties of six blooms Mr. T. W.

Girdlestone was the only competitor, and received the premier award for Mikado, Maize, Demon, Cinderella, Little Frank, Sunningdale Scarlet, Dearest, Prince of Orange, The Yellow Dwarf, and Awdry.

A class was provided for fancy singles, six varieties in bunches of ten. Mr. Girdlestone was first with M.C.C., Tommy, Phyllis, Splash, Irene, and Houri, all striped, splashed, or flaked flowers, and decidedly attractive. Messrs J. Cheal & Sons were second with Jas. Scobie. Stars attractive. Messrs. J. Cheal & Sons were second with Jas. Scobie, Stars and Stripes, Gulielma, May Sharp, Miss Glasscock and Victoria, also a good stand. Mr. Seale was third with Jas. Scobie, Mr. Rose, Mrs. Barker, Duchess of Albany, Victoria, and Gulielma.

CERTIFICATED VARIETIES.

The following novelties received certificates:—May Sharpe (Cheal), a Fancy single, buff with crimson centre, splashed and flaked with the same colour; Mrs. Harris (Cheal), a small Fancy single, very pale lilac, the margins deep carmine; M.C.C. (Girdlestone), a Fancy single, yellow, flaked with vermilion; Tommy (Girdlestone), a very large Fancy single, yellow, with broad crimson flakes and splashes; Phyllis rancy single, yellow, with broad crimson flakes and splashes; Phyllis (Girdlestone), a Fancy single, white, suffused and splashed with rosy magenta; Mrs. A. Peart (Ware), a fine white Cactus, which should turn out an acquisition; Matchless (Perkins), a very fine dark purple Cactus; Scarlet Perfection (Perkins), a beautiful round-flowered single, very rich in colour; Purple Prince (Perkins), a ruby-purple Cactus of the true type; Beauty of Wilts (Pictor), a beautiful and very distinct Cactus, the upper florets broad and flat, the lower tubular and pointed, colour brilliant orange vermilion one of the greatest acquisitions of colour brilliant orange vermilion, one of the greatest acquisitions of recent years so far as the flower is concerned; Lady H. Grosvenor (Keynes), a pale yellow Cactus, lower florets blush; Lady Penzance (Keynes) a beautiful pale yellow Cactus of great size; Chancellor (Keynes), magenta Cactus; Lilacina (Cannell), rich mauve decorative; Rowena (Turner), a charming Pompon, with yellow flowers, heavily tipped with brownish red; Captain Boyton (Turner), a Pompon, very dark blackish purple, perfect shape; and May Hillier (West), an orange salmon Cactus, very large fine flowers.

MISCELLANEOUS.

Messrs. W. Paul & Son, Waltham Cross, had a table of cut Roses in stands and baskets, admirably arranged, as is usual with them. Messrs. Laing & Sons sent a stand of hardy flowers, well representing the extent of their resources, being extremely diversified; and they also had a large group of their splendid Tuberous Begonias, which was greatly admired. Messrs. J. Peed & Son had three very attractive tables, two being filled with hardy flowers and Dahlias, and the other with stove and greenhouse plants. The latter was particularly pleasing, the centre consisting of a harmonious combination of Odontoglossum grande, Eulalia japonica zebrina, Crotons Countess, Aigburthensis, volutus, and Sceptre. Messrs. Cannell & Sons occupied their old position, and were represented by some beautiful Cannas, such as Progression, Alphonse Bouvier, C. Jacob, and J. D. Cabos, also by the charming bronzy orange coloured Begonia Fashion, and an extensive display of Cactus Dahlias, amongst which Cannell's Gem (a distinct and beautiful terra-cotta coloured sort), Lilacina (a decorative variety, with rich mauve flowers), W. H. Cullingford (a light salmon scarlet), Robt. Cannell, Ernest Cannell, and Mr. J. Budde were very prominent. Mr. T. S. Ware had a very large and fine group of Dahlias, the centre being raised in the form of a large shield of blooms, and long lines of others stretching away right and left. Cactus and Pompon varieties formed the greater part of it, but singles were also well represented. Amongst the Pompons was a new variety named Florence Woodland, bright yellow tipped with rose, very pretty and distinct. There were also several new Cactus and decorative sorts, amongst them being Mrs. Peart, claimed to be the long-expected white Juarezi; John Melville, orangescarlet; and J. T. Barber, rich crimson.

HORTICULTURAL SHOWS.

MOSELEY BOTANICAL GARDENS, BIRMINGHAM. AUGUST 29TH, 30TH, AND 31ST.

PRIZES were offered for collections of Apples and Pears, and three collections of 120 dishes each were staged. Messrs. Bunyard & Co., Maidstone, Kent, were first with a splendid collection of first-class quality. Mr. J. Watkins, Pomona Farm, Withington, Hereford, was a good second with fruits not quite so large, but very bright in colour. Messrs. Lane & Son, The Nurseries, Great Berkhamstead, were third with also fine fruit, but not so well up in colour as the two former. In the class for six dishes of Apples, eight fruits of each, Messrs. Bunyard and Co. were first with Stone or Loddington, Peasgood's Nonesuch, Potts' Seedling, Warner's King, Lord Suffield, and Cox's Pomona. This firm was also first for six dishes of Pears, with grand specimens of Dr. Jules Guyot, Pitmaston Duchess, Grosse Calabasse, Marie Louise d'Uccle, Beurré Clairgeau, and Williams' Bon Chrêtien. Other classes were also well filled. It was freely acknowledged to be the finest display by far ever seen in the midlands, and will give a considerable impetus to

hardy fruit culture in the district.

The next feature of the Exhibition were Dahlias, which made a fine display. Four collections in competition were staged, each 15 by 4 feet, and Messrs. Perkins & Sons, Coventry, were first; Messrs. Harkness & Sons, Bedale, second; Mr. G. Maylett, Worcester, third; and Mr. Wm. Shaw, Kidderminster, fourth. These exhibits made up a most attractive bank of Dahlia blooms of all kinds, which were greatly admired. In the class for thirty-six blooms of Dahlias Messrs. Heath and Son, Cheltenham, were first with Mrs. W. Slack, Prince of Denmark, Constancy, Harry Keith, Miss Cannell, Mrs. Saunders, George Rawlings, Maud Fellowes, W. Jackson, Vice-President, R. Dean, Mrs. Wyndham, Rev. J. B. Camm, Majestic, Wm. Keith, Mrs. George Rawlings, Crimson King, Mrs. D. Saunders, T. J. Saltmarsh, Henry Walton, R. T. Rawlings, Eclipse, Harrison Weir, J. T. West, William Rawlings, Mrs. Langtry, Colonist, Mr. Harris, Mrs. Gladstone, Miss L. Large, Flag of Truce, Willie Garratt, Mrs. J. Downie, Lustrous, and Henry Bond—fine, even, well finished blooms. Mr. John Walker, Thame, was second; Mr. George Maylett, Worcester, third; Messrs. Kimberley & Son, Coventry, fourth; and to Mr. W. Shaw, Kidderminster, an extra prize was awarded. For twenty-four blooms Mr. John Walker was first; Messrs. Heath & Son second; Messrs. Harkness & Sons, Bedale, third; Messrs. Kimberley fourth; and an extra to Mr. Shaw. Stove and greenhouse flowers in collections, some excellent Roses from Messrs. Harkness and Son, Townsend of Worcester, and Perkins of Coventry, and various other exhibits in competition were staged. Mr. John White, nurseryman, Worcester, staged a large non-competitive group of Cactus Dahlias, Begonias, Gladioli, and herbaceous and annual flowers and some fruit—a bright and effective display, to which a large silver medal was awarded.

There was also a fine display of vegetables, special prizes having been offered by Messrs. Sutton & Sons (seven exhibits), Mr. T. Wilkins, gardener to Lady Theodore Guest, taking the first prize with one of his customary superb collections, and for twelve massive Onions, in

twelve varieties, a handsome large silver medal was awarded.

BATH.—AUGUST 30TH, 31ST.

THIS popular autumn fixture was favoured with better weather than usual, and it is to be hoped the Committee had good reasons to congratulate themselves upon the attendance of visitors on both days. The arrangements at Bath are always worthy of high commendation, and left nothing to be desired on this occasion. Messrs. Pearson and Jeffery are

arrangements at Bath are always worthy of high commendation, and left nothing to be desired on this occasion. Messrs. Pearson and Jeffery are the Secretaries, and these gentlemen did their work well.

Fuchsias come first in the prize list, but better displays of these have been seen at Bath in former years. Mr. J. Lye, gardener to the Hon. Mrs. Hays, Market Lavington, the veteran grower and raiser of Fuchsias, was well first for nine grand specimens, averaging about 9 feet in height, and perfect pyramids. The varieties consisted of Novelty, Louisa, Balfour, Duchess of Fife, Elegance, Pink Perfection, Charming, Lye's Favourite, Abundance, and Mrs. Rundle, all raised by Mr. Lye. Mr. G. Tucker, gardener to Major Clarke, Trowbridge, was second, his collection comprising an extra good pyramid of Doel's Favourite. The third prize went to Mr. F. A. Lewis, gardener to W. March, Esq., Bath, who had neat well flowered plants. The first prize for six Fuchsias was well won by Mr. W. Marchant, gardener to Jerome Murch, Esq., Bath, who had highly creditable specimens of Charming, Bountiful, Lye's Favourite, Finale, Arabella, and Doel's Favourite. Mr. J. H. Wilcox was second. For four Fuchsias Mr. G. Snell, gardener to Mrs. Counsell, Bath, was a good first; the second prize going to Mr. H. Marchant, gardener to Mrs. Doherty, Bath; and the third to Mr. W. A. Burford. The best single plant of any light variety was shown by Mr. G. Tucker, who had Arabella in good condition. Mr. J. Lye was second in this class, and first for a dark variety, showing in the latter instance a grand pyramid of Charming.

Fairly good prizes were offered for stove and greenhouse plants, and with these Mr. J. Cypher, Cheltenham, was most successful. His

Fairly good prizes were offered for stove and greenhouse plants, and with these Mr. J. Cypher, Cheltenham, was most successful. His first prize collection of flowering and ornamental foliaged plants comprised a fine Bougainvillea, a good Ixora Williamsi, noble Kentias and other Palms, and richly coloured Crotons. Mr. J. F. Mould, Pewsey, was the other prizewinner in this class. Mr. Cypher exhibited in the class for fine-foliaged plants and won. Mr. J. Deacon, gardener to Herbert Harris, Esq., Chippenham, also staged good fine-foliaged plants, and was second, Messrs. E. Cole & Son, Bath, being a good third. Mr. G.

Tucker had the good fortune to be bracketed equal first with Mr. Cypher for six flowering plants, but this decision was not generally approved of. Mr. Cypher had a very fine specimen of Bougainvillea glabra, Clcrodendron Balfourianum and Statice profusa being also fresh and good. Mr. Tucker's best were Ixora Morsei and Stephanotis floribunda. Messrs. Cypher and J. F. Mould were respectively first and second in both classes for Ericas, the plants shown being fresher than might have been expected so late in a forward season.

Exotic Ferns are always remarkably well shown at Bath. The first prize for twelve varieties was won by Mr. G. Tucker, who had Gymnogramma sulphurata, Gymnogramma argyrophylla, Cheilanthes hirta, Dicksonia antarctica, Asplenium nidus avis, Lomaria gigantea, and Adiantums Farleyense, gracillimum, and concinnum. Mr. J. Deacon was a good second, and Messrs. E. Cole & Son third. The best six Ferns were shown by Mr. W. Marchant, who had moderately large and very fresh specimens of Polypodium effusum, Pteris tremula Smithiana, and Adiantums Farleyense, gracillimum, cuneatum, and decussatum. Mr. T. Truckle was second and Mr. H. Marchant third. Mr. Truckle was first in the class for one Fern with a grand plant of Davallia Mooreana, Mr. G. Tucker being second with a good Gymnogramma argyrophylla. Zonal and other Pelargoniums were very well shown, as also were Tuberous Begonias, Cockscombs, Liliums and Petunias. Mr. Cypher was the only exhibitor of six Orchids, and received a first prize for Calanthe veratrifolia, Cattleya aurea, Vanda cærulea, Cypripedium insigne, Oncidium incurvum, and Dendrobium Phalænopsis Schræderiana.

There has been a very marked improvement in the style of groups of plants arranged for effect on a space not less than 100 square feet, though Mr. J. Cypher was easily first. No attempt was made to form a formal background, or such as some judges consider absolutely necessary; but instead of this there were three fairly large groups with elegant central Palms and a series of smaller groups or mounds in front, all being lightly connected with small Ferns, Mosses, and similar plants. The groundwork of the mounds consisted largely of Maidenhair Fern, springing out from which were Orchids, Francoas, elegant Crotons, and other plants. Altogether this was a very charming arrangement. Messrs. Cooling & Son were a good second, a series of groups in front of an undulated background being the style adopted in this case. Rather too many plants were used, but on the whole the effect was very pleasing. Mr. J. Deacon was placed third for a good lot of plants lightly arranged.

Cut flowers occupied a good portion of a large tent and made a very beautiful show. Gladioli were finely shown by Mr. A. A. Walters, Bath, who was first, Mr. T. S. Tottle, Taunton, being second, and Messrs. G. Cooling & Son third. With twenty-four Dahlias, Mr. G. Humphries, Chippenham, was well ahead, the second prize going to Mr. J. Newman, jun., Bath, and the third to Mr. S. Cooper. For twelve Dahlias, Mr. F. Lindsay, Frome, was easily first, and Mr. T. Haskins second. Mr. Humphries was first for Fancies, Mr. T. Haskins second, and Mr. W. Smith, Kingswood, third. Single Dahlias were very showy, and with these the prizewinners were Messrs. Humphries, T. Truckle, and A. A. Walters in the order named. Remarkably good were the Roses, though the judges had no difficulty in awarding the first prize for twenty-four varieties to Dr. Budd, Bath. This capital exhibit consisted of Mrs. J. Laing, Alfred Colomb, Paul Neyron, Prince Arthur, La France, Louis Van Houtte, François Michelon, Mrs. Baker, Harriet Schultheis, Camille Bornardin, Marchinness of Dufferin, Madame Victor Verdier, Ouegn of Bernardin, Marchioness of Dufferin, Madame Victor Verdier, Queen of Queens, Star of Waltham, Marie Van Houtte, Gustave Piganeau, Catherine Mermet, Duchesse de Morny, Edith Gifford, Marie Margot, Maréchal Niel, Duchess of Bedford, Comtesse de Nadaillac, and E. Y. Teas. Mr. T. Hobbs, Bristol, was a good second, A. Hill Gray, Esq., Bath, was third. Another excellent stand of blooms was staged by Dr. Budd in the class for twelve; Messrs. G. Cooling & Son were a good second. With twelve Teas, A. Hill Gray, Esq., was first, having splendid blooms. Dr. Budd was second, and Mr. T. Hobbs third. Zonal Pelargoniums made a fine display, and with twenty-four bunches of these Mr. G. Humphries was first. Messrs. Cooling & Sons were second, and Mr. E. Hall third. Asters were numerous and good, and with these the principal prizewinners were Messrs. W. J. Jones, H. Hooper, A. A. Walters, and S. Every. Mr. F. Hooper, Bath, was first for Hollyhocks, and Mr. W. Smith second. Herbaceous flowers in bunches were grandly shown. With these Mr. M. Pritchard, Christchurch, was first, Mr. A. A. Walters second, and Messrs. Cooling & Sonsthird. The first prize for twenty-four bunches of annuals was well won by Mr. A. H. Newman, Bath, Mr. F. Hooper being second, and Mr. G. Garraway, Bath, third. Mr. Kitley, gardener to E. Hall, Esq., Yeovil, was first for twenty-four bunches stove and greenhouse flowers, Mr. H. Marchant being second, and Messrs. E. Cole & Son third. Mr. F. Case took a first prize for a hand bouquet, Mr. G. Hallett being second. Very well arranged was the first prize vase shown by Mr. J. Cypher, R. B. Cater, Esq., being a very creditable second.

Fruit was shown in splendid condition. Three remarkably good collections of twelve dishes were staged, only a very few points separating them. Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, was rightly placed first, having extra fine Alicante and fairly good Muscat of Alexandria Grapes, pretty Golden Gem and Hero of Lockinge Melons, good Dymond and Violette Hâtive Peaches, Humboldt and Victoria Nectarines, large Williams' Bon Chiêtien Pears, Brown Turkey Figs, and Worcester Pearmain Apples. The second prize went to Mr. C. Warden, gardener to Sir F. R. Bathurst, Salisbury, whose best dishes were Alicante Grapes, Lord Palmerston and Sea Eagle Peaches, and Flemish Beauty Pears. Mr. W. Strugnell, gardener to W. H. Long, Esq.,

M.P., Rood Ashton, followed very closely. Five competed with eight bunches of Grapes in four varieties, and it was no easy matter to decide which were best out of the three leading collections. Mr. W. Taylor, gardener to Alderman Chaffyn, Bath, was placed first, his Gros Maroc and Alnwick Seedling being very fine, but the Black Hamburghs were not so good in colour, and Muscat of Alexandria not fully ripe. Mr. C. Warden was lucky in being placed second, for good as his Grapes were the most even and really the smartest exhibit was staged by Mr. W. Nash, who came third. The Alicantes staged by both Mr. Warden and Mr. Nash were very good in every way. Mr. T. Jones, Bath, was well first for three bunches of Black Hamburgh, Mr. Nash being second, and Mr. J. Atwell, gardener to J. B. Brain, Esq., Clifton, third. other class for black Grapes, Mr. Marsh, gardener to Miss Marriott, Bath, had grand bunches of Alicante, Mr. Nash being a good second with the same variety, and Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, who also showed really good Alicante, third. the Muscat of Alexandria, Mr. W. Iggulden, gardener to the Earl of Cork, Frome, had the honour of beating the redoubtable Mr. W. Taylor, Mr. T. Jones being third. Mr. Taylor's bunches and berries were very fine, but Mr. Iggulden's fairly large bunches were much the ripest. In the any other class for white Grapes, Mr. Marshall, gardener to J. Dale, Esq., Clifton, was first with grand Buckland Sweetwater, and Mr. J. Atwell second with the same variety, the third prize going to Mr. Warden for pretty bunches of Mrs. Pearson. In the local class for Grapes many good bunches were shown, Mr. Marsh being first with Alicante; and Mr. J. Tickell, gardener to Mrs. Stoddart, second with good Muscat of Alexandria.

Melone were not particularly well shown, and with these the principal prizetakers were Mr. R. Hill, Chippenham; Mr. S. Hodges, gardener to J. Fortt, Esq., Bath; and Mr. C. Gliddon, gardener to Mr. Waller. Peaches were both numerous and good, Messrs. T. Jones, H. Hopkins (gardener to H. Prodgers, Esq.), and J. Ricketts taking the principal prizes. Few Nectarines were shown, Mr. Strugnell taking the first prize, this exhibitor also being suecessful in three different classes for Plums. Filberts and Cobnuts were remarkably good, and so also were the Apples and Pears. In these classes the judges acted very inconsistently, sometimes going for quality and sometimes for great size. A grand dish of Peasgood's Nonesuch, staged by Mr. J. B. Payne, caused quite a sensation. The heaviest fruit weighed 22 ozs. and the rest were nearly as heavy, all being of good form and beautifully coloured. In addition to taking a first prize a silver medal was also awarded this exhibit. Special prizes were offered for Melons by Messrs. Sutton & Sons, and good fruits were staged. The principal prizewinners were Messrs. Adlam, Allen, Pymm, staged. The pri and C. Gliddon.

Vegetables were never before so extensively shown at the Bath autumn show, several seedsmen offering prizes for collections and single dishes. Mr. G. H. Copp, gardener to W. E. E. Erlc Drax, Esq., Sherborne; Mr. T. Wilkins, gardener to Lady Theodore Guest; Mr. F. Williams, Mr. G. Garraway, and Mr. J. Hall divided honours very evenly, all showing remarkably well.

Non-competitive exhibits included an excellent display of hardy trees and shrubs, Gladioli, herbaceous flowers, Dahlias, Liliums, and Alpines staged by Messrs. Robert Veitch & Son, Exeter; a fine exhibit of single and double Tuberous Begonias by Mr. B. R. Davis, Yeovil; two large stands of garden Roses, and some fine Apples by Messrs. G. Cooling

and Sons.

SANDY.—AUGUST 31ST.

In the park of Sandy Place, by kind permission of Mrs. Foster, the Sandy and District Floral and Horticultural Society held its twenty-fifth annual Exhibition on the above date. For many years past this Show has been held on the last Friday in August, but this season the day was changed to the last Thursday, with the consequence of losing several of its most valuable exhibitors, more especially in the classes for stove and greenhouse plants. Notwithstanding this, however, the Show was an excellent one, some splendid produce being staged. About two o'clock in the afternoon—the time at which the visitors from some distance away usually arrived—the rain commenced to descend in torrents, and continued to do so for some considerable time, completely spoiling the grass for walking, as it was thoroughly soddened by the downpour. This, on the first occasion of the change of day, was most unfortunate, as instead of getting an increased number of visitors, as the Committee hoped and expected, there was doubtless a large falling off in the The arrangements of the Show were complete and good, attendance. much credit being due to E. T. Leeds-Smith, Esq., the Hon. Secretary Mr. William Green, Secretary, and the Committee of Management for the zeal and energy they had displayed in bringing together such an excellent and thoroughly representative exhibition. Let us hope that the Show was as great a success from a financial point of view as it most undoubtedly was from the horticultural standpoint. We append a list of prizewinners in the principal classes, the awards being made by the following gentlemen:—Mr. J. Myers, gardener to Earl of Sandwich, Hinchingbrook House; Mr. Kipling, gardener to Lord Lytton, Knebworth. Cut flowers, Mr. W. Finch, gardener to Mr. Marriott, Coventry; Mr. R. Cut howers, Mr. W. Finch, gardener to Mr. Marriott, Coventry; Mr. R. Carter, gardener to Capt. Duncombe, Waresley Park. Fruit, Mr. G. Norman, gardener to the Marquis of Salisbury, Hatfield House; Mr. Maycock, gardener, Luton Hoo. Vegetables, Mr. Landers, gardener to Mr. S. Whitbread, Southill Park; Mr. W. Ratchelous, the Nurseries, St. Neot's. Cottagers' tent, Mr. G. R. Allis, gardener to Major Shuttleworth, Old Warden; Mr. W. J. Empson, gardener to Mr. A. H. Wingfield, Ampthill House.

In the class for ten distinct stove and greenhouse plants in flower

there were two competitors, Mr. Finch, gardener to J. Marriott, Esq., Coventry, who was placed first with fine specimens, and Mr. George Redman, Eynesbury, to whom the judges awarded the third prize. The winner's exhibit was composed of Clerodendron Balfourianum, Statice imbricata, Ixora Duffi, I. Williamsi, I. javanicus floribundus, Dipladenia amabilis, Erica Marnockiana, E. Aitoniana Turnbulli, Allamanda grandiflora, and Rodeletia speciosa major, all of which were grand examples of good culture and thorough training. Mr. Dale, gardener to Mrs. Foster, Sandy Place, was accorded the first position or twelve Zonal Pelargoniums, showing clean, well flowered plants of the following varieties:—Gambetta, Mrs. Robertson, Hermia, Queen of the Belgians, Laura Strachan, Thetis, Henry Jacoby, Madame Thibaut, Ianthe, Lucy Bosworth, Rev. F. Atkinson, and Lord Chesterfield. The second and third prizes were awarded to Mr. Empson, gardener to Mr. A. H. Wingfield, Ampthill, and Mr. Redman in the order of their names. Though only three exhibits were staged in this class the competition was most keen, the plants in each case being highly creditable. Empson was awarded the first prize for a group of plants, which included Palms, Crotons, Achimenes, Liliums, Ferns, and Tricolor Pelargoniums. Mr. Claydon, gardener to Mrs. Astell, Woodbury Hall, Sandy, was In the class for six foliage a good second, and Mr. Redman third. plants, distinct, Messrs. Empson, Claydon, and Redman were again awarded the prizes in the order in which they are named.

The second prize only was accorded in the class for six stove and greenhouse plants in flower, and it was given to Mr. Claydon, who staged Stephanotis floribunda, Anthurium Andreanum, cathartica, Dipladenia amabilis, and Plumbago capensis alba. In the class for six Coleuses in distinct varieties Mr. Redman was first and Mr. Empson second. The winner's plants were small, but of excellent shape and fine colour. Mr. Claydon was a worthy first for six stove and greenhouse Ferns, his plants being magnificent examples, which reflected high credit on the grower. The exhibit comprised Adiantum grandiceps, A. farleyense, A. formosum, A. gracillimum, A. cuneatum, and Dicksonia antarctica. The second prize was taken by Mr. Empson with fine plants, and the third by Mr. Redman. E. T. Leeds-Smith, Esq., Sandy, was placed first for six hardy Ferns, the third prize being taken by Mr. Redman. Mr. Claydon gained the premier award for six pots of Achimenes, staging healthy and profusely flowered examples. The third prize was won by Mr. Redman. For four Cockscombs Mr. Claydon was again first with beautiful examples, Mr. Redman being second, and Mr. A. Burgess, Wimpole, third. In the Redman being second, and Mr. A. Burgess, Wimpole, third. In the class for six Begonias in flower, distinct, Mr. Claydon was a good first, and Mr. Addington, St. Neot's, second. Mr. Finch was first for a specimen stove or greenhouse plant in flower with Erica Marnockiana Mr. Finch was first for a in grand condition. Mr. Finch was also first for a specimen foliage plant, staging Dracæna indivisa lobata in very fine form.

The cut flower classes were not as a rule keenly contested, though some very handsome blooms were shown, particularly amongst the Gladioli from Messrs. Burrell & Co., and the Roses from Mr. George Moules, Hitchin. In the class for twenty-four bunches of herbaceous plants, Messrs. Laxton Bros., Bedford, were an excellent first. Amongst the flowers in this stand were Anemone japonica, Helianthus multiflorus plenus, Lychnis chalcedonica plena, and Chrysanthemum maximum. Mr. Hunt, Sandy, was awarded the second prize for a highly creditable exhibit. For twelve bunches of Pompon Dahlias, six blooms in each bunch, Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, were placed first with a fine stand, which was composed of Cupid, White Aster, Mabel, Favourite, Whisper, Isabel, Fairy Tales, Admiration, Phoebe, Red Indian, Darkness, and E. F. Junker. Mr. R. Burgin, Eynesbury, was placed second with a creditable exhibit. Messrs. J. Burrell & Co. were again awarded the first prize in the class for twelve bunches of Cactus Dahlias, six blooms in each bunch. The following were the varieties staged: Experite Marchiness of Parts Palest. were the varieties staged:—Kynerith, Marchioness of Bute, Robert Maher, Baron Schröder, Juarezi, Baldwin, Amphion, Delicata, H. Freeman, Duke of Clarence, Bertha Mawley, and Black Prince. In the class for twenty-four spikes of Gladioli, in not less than eighteen distinct varieties, Messrs. J. Burrell & Co. were placed first, their stand including some magnificent spikes of beautifully coloured blooms. Amongst the best may be mentioned Le Vesuve, Rosalind, Baroness Burdett Coutts, Delicata, Madeline, Glow, Hilda, Formosa, and Letitia. Mr. S. Wilkinson, was placed third. Mr. George Moules, Hitchin, easily carried off the highest award for six Roses in distinct varieties, staging some beautiful blooms.

Fruit was finely staged, though it was not very extensive; but this may perhaps be accounted for by the fact of the great Show at the Agricultural Hall being open at the same time, and thus drawing many of the exhibitors southwards as far as London. Mr. G. R. Allis, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, was awarded the first prize and a silver medal for a collection of fruit of eight distinct Dishes of Apples, Pears, Plums, Peaches, Nectarines, and Grapes Black Alicante and Foster's Seedling comprised the exhibit, which was a meritorious one, the value of which would have been much enhanced had Mr. Allis troubled to give the specific names in each case. James, Stevenage, was a good second; Mr. Empson a close third, and Mr. Burgess fourth. In the class for six distinct kinds of fruits Mr. G. Cranfield, Cambridge, was deservedly accorded the first place, showing black and white Grapes, Melon, Peaches, Apples, and Figs. Mr. C. Forbes was a fairly good second, and Mr. R. Carter third. Mr. Allis was first in the class for any black Grape other than Hamburgh with two bunches of Black Alicante, Mr. Empson being second with Madresfield Court, and Mr. Moore third. In the class for two bunches of Black

Hamburgh Grapes Mr. Moore, St. Neots, was first with splendid examples; Mr. G. R. Allis second with good bunches, and Mr. Cranfield third. Mr. Empson was first for two bunches of Muscat of Alexandria Grapes, staging a highly creditable pair; Messrs. Forbes and Cranfield being second and third in the order of their names. Mr. James was awarded the first prize for a dish of Figs grown out of doors with fine fruits of Black Ischia. Mr. James was again first in the class for a dish of dessert Plums, staging highly creditable fruits of Lawrence's Gage, the second, third, and fourth prizes going to Messrs. Burgess, Claydon, and Maudlin. The competition was remarkably keen in this class, fifteen dishes of Plums being staged. Mr. Claydon, with beautiful fruits of Pond's Seedling, took the premier award in the class for a dish of culinary Plums; Mr. Wilkinson being second, Mr. Allis third, and Mr. Wade fourth. The exhibits in this class numbered ten, so that competition again ran very keen. The class, however, which brought the highest number of exhibits was for a dish of eight dessert Pears, seventeen competitors being represented. Mr. James was awarded the first prize, Mr. Empson being second, and Mr. Hobbs, St. Ives, third. Mr. Empson was first in the class for five culinary Pears, Mr. James second, Dr. Swain, Three Counties Asylum, third, and Mr. Wade fourth.

Vegetables, as may have been expected, were not largely shown, but those staged were most of a very high order of merit. This was particularly the case with the Onions, Carrots, and Turnips. Celery was exceptionally good, and some of the Red Cabbages staged were enormous. In the class for a basket of vegetables in twelve kinds, Mr. Empson was first with a clean well-grown collection, which included Potatoes, Onions, Turnips, Tomatoes, Celery, Globe Artichokes, Cauliflowers, Carrots, Marrows, and Cucumbers. Mr. Burgess was a very good second, Mr. G. Wood being third, and Mr. F. Faints, Hertford, fourth. Mr. Carter was accorded the first prize for a basket of six kinds of vegetables. This exhibit was composed of Potatoes, Onions, Turnips, Tomatoes, Peas, and Cauliflowers. The second prize was won by Mr. Andrews with a good basket. For a collection of Potatoes, to include three round and three kidney varieties, named, six tubers of each, Mr. T. Clark, Huntingdon, was first with The Queen, Suttons' Satisfaction, Uncle John, Lord Tennyson, Reading Russet, and Reading Ruby, all of which were in excellent condition. Mr. Hemmants, Peterborough, was deservedly accorded the second prize.

Messrs. Cutbush & Son, nurserymen, Highgate, arranged a very effective group of greenhouse and stove plants, in which Crotons Queen Victoria, Disraeli, Majesticus, Mrs. Dorman, Dracæna Doucetti, Abutilon Souvenir de Bonne, and Palms were very striking and effective. Messrs. Laxton Brothers, Bedford, staged a collection of blue Sweet Peas and a magnificent cross of white flowers. Mr. Willcock, nurseryman, Bedford Road, Sandy, exhibited a group of foliage plants, in the arrangement of which much taste was displayed; the clean healthy Palms were a particularly noticeable feature in this group. The three last-named exhibits were not for

competition.

BRIGHTON.—SEPTEMBER 5TH AND 6TH.

THE autumn Exhibition, held under the auspices of the Brighton and Sussex "New" Horticultural Society, took place on Tuesday and Wednesday last, when an exceptional display of produce was staged. The Show, which was held in the Corn Exchange and the Dome, was of unusual dimensions; so numerous in fact were the exhibits that it was found necessary to erect three tents to provide adequate space in which to place them. As has been said, the display was in every way a grand one, and when it is mentioned that six exhibits were arranged in the class for a group to be arranged for effect in a space not exceeding 150 square feet, and twenty-nine dishes in the class for dessert Pears, some idea will be conveyed of the magnitude of the Show. The Judges had a very hard task in adjudicating on the stands, but their awards appear to have given every satisfaction. Great credit is due to Mr. Mark Longhurst, the Secretary, Mr. Lewis, and other members of the Committee for the industry they must have displayed in the arrangements of the Show, which were in every way complete.

In the class for six stove and greenhouse plants in bloom the first prize went to Mr. T. Portnell, gardener to Sir A. Lamb, Bart., Beauport, Battle, who staged good specimens of Bougainvillea glabra, Allamanda magnifica, Lapageria rosea, Erica Irbyana, Dipladenia Brearleyana, and Erica Aitoniana Turnbulli. The second prize was awarded to Mr. A. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley; Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Withdeane, being a close third. The competition in the class for six stove and greenhouse foliage plants was keen, Mr. Offer was accorded the premier position; the second and third prizes were awarded to Mr. E. Meachen and Mr. W. Peel, gardener to Miss Todd, Sidford Lodge, Shirley, Southampton, in the order named. For six stove and greenhouse Ferns Mr. Offer was deservedly accorded the first prize with splendid examples, the second prize going to Messrs. W. Miles & Co., nurserymen, Hove; third, Mr. W. Peel. For a specimen foliage plant Mr. Offer was first with fine plant of Croton Warreni, Mr. W. Peel being second, and Mr. Portnell third. Mr. Offer was again first for a specimen flowering plant, showing Lapageria rosea in grand condition, Mr. L. Budworth, gardener to C. Hill, Esq., Rockhurst, West Hoathley, second with a good Dipladenia hybrida; third going to Mr. W. Peel.

In the class for six Tuberous-rooted Begons the competition was

very keen, Mr. Head, The Drive Nursery, West Brighton, being a good first with finely flowcred plants; the second prize being won by Mr. Jas. Dawson, Silverhill, St. Leonards, and the third by Mr. E. Meachen. Mr. E. Mcachen was first for six Fuchsias, showing Grand Duchess Maria,

Mrs. Rundle, and Mrs. Burroughs; Mr. J. Hill, gardener to M. Wallis, Esq., Withdean, being a good second. Mr. Murrell, gardener to Mrs. Esq., Withdean, being a good second. Mr. Murrell, gardener to Mrs. Macdonald, Manor House, Preston, was first for six Zonal Pelargoniums with excellently bioomed plants; Mr. Meachen was second, and Mr. H. Head third. Groups were well shown, six competitors staging exhibits in the leading class. Mr. Wills was awarded the first prize for a beautiful arrangement. Amongst the best of the plants were Palms, Francoa ramosa, Tuberoses, Celosias, Carnations, Crotons, Eucharises, with a groundwork of Ferns. Mr. W. Peel was a very close second. Tuberoses Liliums Crotons, Palms and Amerallies were noticeable in Tuberoses, Liliums, Crotons, Palms, and Amaryllises were noticeable in this exhibit. Mr. E. Meachen was a very close third. In the class tins exhibit. Mr. E. Meachen was a very close third. In the class for a group arranged in a space not exceeding 80 square feet, Mr. G. Sims, gardener to C. J. Inwood, Esq., Dyke Road, Brighton, was placed first for a beautiful group, Palms, Liliums, and Begonias being particularly prominent; Mr. Budworth was second with a somewhat heavy arrangement, and C. W. Catt, Esq., Middle Street, Brighton, being third. For a group of Ferns, Rev. Sir G. C. Sheffner, Lewes, was first, Messrs. W. Miles & Co. second, and Mr. G. Miles third.

Cut flowers were very largely shown, especially Dahlias, which were exceptionally fine. In the class for a box of stove and greenhouse flowers Mr. Portnell was first. This exhibit included Vallota major, Statice Gilberti, and Anthurium Scherzerianum amongst others. Mr. Horscroft, gardener to T. Potter, Esq., Hapstead House, Ardingly, was second, and Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Preston Park, third. Mr. Archer, gardener to Miss Gibson, Hill House, Saffron Walden, was first in the class for a box of cut blooms in twenty-four distinct varieties. Amongst the most prominent in this stand were Allamanda Hendersoni, Eucharis amazonica, Dipladenia amabilis, Lapageria alba, and Ixora Williamsi. Messrs. J. Cheal & Son, Crawley, were successful in the classes for single, Pompon, Cactus, and double Dahlias. In the class for twenty-four single Dahlias they staged a grand collection, amongst which The Bride, Amos Perry, Miss Henshaw, Formosa, amongst which The Bride, Amos Perry, Miss Henshaw, Formosa, Cetewayo, and May Thorpe were conspicuous. Mr. E. Such, nurseryman, Maidenhead, was second. In the class for Pompon Dahlias Messrs. Cheal staged Sunshine, Admiration, Isabel, Favourite. and Arthur West in exceptionally good form. Mr. Humphries, nurseryman, Chippenham, was second, and Mr. E. Such third. Amongst the best of Messrs. Cheal's Cactus blooms must be mentioned Robert Cannell, Black Prince, Delicata, Duchess of York, Sir Roger, and Josephine. Mr. Humphries was second, and Mr. Such third. In the class for twenty-four Show and Fancy varieties Messrs. Cheal & Son showed, amongst others, Wm. Rawlings, J. T. West, Goldfinder, Mrs. Jefford, Mrs. Kendal, and Crimson King. Mr. Mitchell, gardener to Sir Jas. Colquhown, Bart., Hastings, was a good second, and Mr. Jas. Dawson third. The classes for herbaceous flowers were very keenly contested. Messrs. Garroway, Bath; Goldsmith, gardener to Sir E. Loder, Horsham; Manton, gardener to Mrs. Clifford Bonner, Bolney; and E. Such being amongst the most successful competitors. Roses were fairly well shown by Messrs. Garroway, T. Durrant; Young, Eastbourne; Geo. Piper, Uckfield, and Woollard, Lewes The table decorations were very beautiful, and highly creditable to the various exhibitors.

The display of fruit was a grand one, the entries being large in almost every class. The Grapes were fine, the bunches as a rule being of good size, symmetrical in shape, and of perfect finish. Peaches were also good, the colouration in some of the fruits being quite exceptional. Melons were shown in excellent condition, as also were Plums and Green Gages. In the four classes devoted to Apples the entries reached the good total of sixty-four, and the fruit being of superb quality the competition ran very high and close. But it was in the class for a dish of dessert Pears that the exhibits reached the highest total, there being twenty-nine dishes staged. Some fruits of Souvenir du Congrès, shown by Mr. Spottiswood, The Gardens, Queen's Park, Brighton, were deservedly awarded the premier position. They were in excellent condition and beautifully finished. The second prize was accorded to Mr. Goldsmith, and the third to Mr. J. Collins. In addition to these prizes some of the exhibits were of such merit that the judges strongly recommended that extra prizes should be given. The number of fruits to compose a dish in the above class was six, so that the exhibits took up a very large amount of tabling.

Vegetables were not staged in such great numbers as fruit, but the quality throughout left little to be desired. This was particularly the case in the classes for French and Runner Beans, these being shown in strong force and first rate quality. Beet was grand, clean shapely roots being staged. There were five collections staged in the class for nine distinct kinds of vegetables, some good produce being exhibited. The first prize went to Mr. Garroway, Bath, who staged Autumn Giant Cauliflowers, the Lyon Leeks, White Plume Celery, Webb's Giant Runner Beans, Oxonian Tomatoes, Abundance Potatoes, Duke of Albany Peas (perhaps the only weak point), and Pragnell's Exhibition Beet. Mr. A. Ward, Muntham, Horsham. was placed first for a collection of vegetables in six kinds. This exhibit consisted of Vicar of Laleham Potatocs, Perfection Tomatoes, Sutton's Al Onions, Snowball Turnips, Mammoth Cauliflowers, and Intermediate Carrots, which together formed a highly creditable exhibit. The special prize offered by Messrs. J. Cheal & Son for a collection of vegetables brought only one competitor, Mr. Sands, gardener to T. Bannister, Esq., Hayward's Heath, being successful. In the class for a collection of Potatoes in six distinct varieties Mr. Kemp, gardener to R. S. C. Dickens, Esq., Horsham, was placed first out of the nine competitors, the exhibit being an excellent one in every way. The following varieties were staged by the winner: Sutton's Best of All

Satisfaction, Beauty of Hebron, Early Puritan, Schoolmaster and Snow-

Miscellaneous exhibits, although not very numerous, were good. Messrs. J. Cheal & Sons arranged a large table with Apples, Pears, and Dahlias. Amongst the best of the Pears were Williams' Bon Chrêtien, King Edward, and Belle de Bruxelles; and of Apples Queen, Cox's Orange Pippin, Yorkshire Beauty, King of the Pippins, and Mère de Ménage. Messrs. E. D. Shuttleworth & Son, Peckham Rye, and Fleet, Hants, showed a charming table of plants, prominent amongst which were Crotons, Carnations, Liliums, and Ferns. Messrs. Balchin and Son, Hassocks Nurseries, had a stand devoted to bulbous roots, which produced an excellent effect; and Messrs. Tilley Bros., Brighton, one of bulbs and horticultural sundries.

ROYAL AQUARIUM.—SEPTEMBER 6TH, 7TH, AND 8TH.

An exhibition of early Chrysanthemums, Dahlias, and Gladioli was held at the Royal Aquarium, Westminster, on the above dates. The principal class for Chrysanthemums was for twenty-four bunches, not less than three flowers in each bunch. There were two competitors, and the first prize went to Mr. E. F. Such, Maidenhead, for a charming collection of fresh blooms. Mr. Davis was second. Mr. H. Shoesmith, gardener to W. Hodgson, Esq., Shirley Cottage, Croydon, was first with twelve blooms of Madame C. Desgranges, showing fairly developed flowers for the season. Mr. W. C. Pagram, gardener to A. F. Hobhouse, Esq., The Whin, Weybridge, was awarded the second prize. Mr. Shoesmith was given the third prize for a dozen blooms of Mrs. Burrell. For twelve blooms of any large flowering variety except Madame C. Desgranges, Mr. J. Agate, Havant, was first. The second prize went to Mr. A. McMillan, gardener to Jas. Curie, Esq., Trinity Cottage, Edinburgh.

Mr. D. B. Crane, Archway Road, Highgate, secured the premier prize for twelve Pompons, three flowers of each, Miss Debenham, St. Peter's, St. Albans, being second. Mr. W. C. Pagram was first with six bunches of Madame C. Desgrange, and Mr. Shoesmith second. The same exhibitors secured the prizes for six bunches of any yellow variety of Madame C. Desgrange. There were also only two competitors in the class for six blooms, distinct, these being Mr. McMillan and Mr. Agate. The prizes were awarded as their names are given. Mrs. Walter Mole, High Street, Hemel Hempsted, was first for a stand of Chrysanthemums for table decoration; Mr. W. Smith, Romford, second; and Mr. D. B. Crane third. A silver medal was also awarded the last-named exhibitor for twelve bunches of Chrysanthemums.

Dahlias formed the bulk of the exhibits. There were two competitors in the class for twenty-four bunches of single Dahlias, these being Messrs. J. Cheal & Sons, Crawley, and Mr. F. W. Seale, Sevenoaks. Mr. G. Humphries won the first prize for twelve bunches of single Dahlias, Mr. E. F. Such being second. Messrs. Keynes, Williams & Co., Salisbury, secured the first prize for twelve bunches of Cactus Dahlias, showing fine blooms. Messrs. J. Burrell & Co., Cambridge, followed closely with a stand of fresh flowers, the third prize going to Messrs. Cheal & Sons.

Pompon Dahlias were very good in all classes. For twenty-four bunches Messrs. J. Cheal & Sons were placed first for a splendid stand of flowers. The most conspicuous in this collection were Marion, Cecil, Whisper, Eva, Sunshine, Admiration, and Ariel. Mr. C. Turner, Royal Nurseries, Slough, was a close second with very fine flowers, the third prize going to Messrs. Keynes, Williams & Co. Messrs. J. Burrell & Co. had the best stand of twelve bunches, Mr. G. Humphries following. In the amateurs' and gardener's classes Mr. J. J. West, gardener to W. Keith, Esq., Brentwood, was first with six bunches of Pompon Dahlias, the second prize going to Mr. Richard Burgin, Eynesbury, St. Neots. The last-named exhibitor had the best six bunches of singles in this section, Mr. E. Mawley, Rosebank, Berkhamstead, following; the third prize going to W. Mist, Esq., Ightham, Sevenoaks. Mr. West was first with six bunches of Cactus Dahlias in this division, Mr. Mawley being second, and Mr. William Hopkins, New Passage, Bristol, third.

The Show and Fancy Dahlias were remarkably fine and even. For sixty blooms of not less than thirty varieties Mr. C. Turner was placed first with an excellent stand. Messrs. Keynes, Williams & Co. followed closely, showing splendid flowers, the third prize going to Mr. J. Walker, Thame. There were five competitors in this class. Messrs. Keynes, Williams & Co. were, however, first for thirty-six blooms, distinct, amongst which William Powell, Pelican, James Cocker, T. W. Girdlestone, Rebecca, and William Rawlings were conspicuous. There were two blooms of Arthur Ocock, and labelled thus, in this collection, but this matter appears to have been overlooked by the Judges. Mr. J. Walker, Thame, was second, the third prize going to Mr. C. Turner.

Walker, Thame, was second, the third prize going to Mr. C. Turner.

Messrs. Saltmarsh & Son, Chelmsford, secured the first prize for
twenty-four Dahlias, Messrs. Humphries and Rawlings following. Mr.
West was placed first with twenty-four blooms in the gardeners' and
amatcurs' division, Messrs. A. Ocock and Burgin following in order of
their names. Mr. Ocock was first with eighteen blooms, the second
prize going to Mr. West, and the third to Mr. W. Mist. Mr. Thomas
Vagg, gardener to J. Theobald, Esq., M.P., Bedfords, Havering, near
Romford, was first with twelve blooms, distinct; Messrs. J. Gurney
Fowler, South Woodford, and W. Hopkins being second and third.
Messrs. Gurney Fowler, T. Vagg, and W. Hopkins secured the prizes
for six blooms.

Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, were the only exhibitors of a collection of Gladioli, but for which the first prize was awarded. The spikes were, on the whole, very fine. Mr. C. J. Waite, gardener to Col. the Hon. W. P. Talbot, Glenhurst, Esher; and Mr. C. Osman, South Metropolitan District Schools, Sutton, Surrey,

secured the special prizes offered by Messrs. Sutton & Sons for a collec-

tion of vegetables.

Miscellaneous exhibits were not so numerous as we have seen them at the Aquarium. Messrs. J. Laing & Son had a large collection of hardy flowers, for which a silver medal was awarded. The same firm also sent a very fine collection of Apples and Pears, comprising about ten dishes (silver medal). Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, staged a splendid collection of Dahlias of various kinds, arranged in a most effective manner. A silver-gilt medal was awarded. Mr. W. Piercy, West Road, Forest Hill, S.E., sent some early flowering Chrysanthemums. Messrs. Kcynes, Williams & Co. staged Show and Fancy Dahlias, as also did Messrs. Saltmarsh & Son. Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, The Palace, Wells, Somerset, was awarded a silver medal for a dish of remarkably fine and well coloured Peasgood's Nonesuch Apples, the heaviest of which weighed 22 ozs. Mr. A. Rawlings, Romford, Essex, had a number of Dahlias, and a silver medal was awarded. Messrs. Perkins & Sons, S. Mortimer, T. S. Ware, and other growers sent some new Dahlias to be inspected by the Floral Committee; but when our reporter left no certificates had been awarded.

FRUIT FORCING.

Peaches and Nectarines .- Larliest Forced Trees .- These are assumed to consist of very early varieties which were started from December 1st to the new year. The trees have now shed their leaves, and, if infested with red spider or brown scale, they may be syringed with water at a temperature of 140°. It must not, however, be used injudiciously; if too hot it will injure the young wood and buds, and if lower in temperature it is innocuous as regards scale and red spider about to hybernate. The trees should be loosened from the trellis and tied in bundles for facilitating cleansing operations, then wash the woodwork with soap and a brush, also the ironwork, reaching every angle and crevice. Limewash the walls, and if required paint the wood and ironwork. Pruning will consist of thinning the shoots where crowded or too weak for carrying fine fruits, no shortening being necessary, except for shoots unduly long or for the production of growths for extension. The trees may be washed with a softsoap solution, 3 ozs. to a gallon of water, or dressed with an approved insecticide, being careful not to dislocate the buds. Tie the trees to the trellis loosely, leaving sufficient room for the swelling of the branches and shoots; remove the loose surface soil down to the roots, and supply a top-dressing of rather strong turfy loam with a fourth of well decayed manure admixed, and afterwards sprinkle a handful (about 4 ozs.) over a square yard of the following mixture: bonemeal three parts, and kainit one part, leaving it there. Avoid heavy surface dressings, they only exclude air and render mulchings of little value by burying the roots too deeply. If the lights have been removed they need not be replaced until the weather become colder and the borders have been thoroughly moistened by the autumnal rains.

Second Early-forced House.—The trees are shedding the leaves, but there must not be any attempt at their forcible removal. When the leaves have fallen treat the house and trees the same in every respect as

detailed in the preceding paragraph.

Succession Houses.—Any trees that have a tendency to over-luxuriance should, as soon as the wood gets sufficiently matured, have a trench taken out about one-third the distance from the stem the trees cover in extent of trellis and quite down to the drainage, so as to detach all roots, and this may be left open for a fortnight and then be filled in firmly; or when the leaves give indications of falling the soil may be removed down to the roots with a fork and picked from amongst them, laying in the roots in fresh compost, and making quite firm. Good loam, rather stiff, with about a sixth of old mortar rubbish, form a suitable compost. A watering being given the roots will soon work freely in the fresh material, and the fruits invariably set and stone well afterwards. The above plan is more especially necessary with young trees, the taking out of the trench being very effectual in assisting them to ripen the wood thoroughly. Lifting and root-pruning generally should be deferred until the leaves give indication of falling, for if practised too early there is danger of causing the sudden collapse of the foliage and the shrivelling of the wood.

Late Houses.—The bright weather has greatly assisted late Peaches and Nectarines, which are not only much earlier in ripening than usual, but something wonderful in size and beauty, and where proper supplies of water and nutriment have been provided during growth the fruits are singularly juicy and high flavoured. Gladstone is unquestionably one of the finest late Peaches, and though not high coloured has a rather firm flesh and travels well. Late Peaches will, no doubt, be scarce this year through their ripening being accelerated by the hot summer, and the wood is more advanced in ripening than in ordinary seasons. A free circulation of air and the necessary supplies of water are necessary, but a rather drier condition at the roots is desirable when the fruit is ripening. Keep the growths thin, stop any growing shoots to about 15 inches and all laterals closely to one joint as growth is made.

Pines.—Young Pine plants always present a luxuriant appearance at this season under proper treatment, this arising from the beneficial effects of natural causes so important in cultivation. Those influences being now on the wane, greater care will be necessary in the management to prevent the growth becoming soft, and measures should be taken to consolidate it by a drier atmosphere, and, if necessary, artificial heat. Syringing will only be needed occasionally, and it should be done early in the afternoon of bright days. Water must only be given when absolutely necessary, then afford a plentiful supply of weak liquid manure in a tepid state. The bottom heat should be kept steady at 85°, or between 80° and 90°. Particular attention must be paid to the ventilation, which is very important at this period of the year. Plants in a luxuriant condition should have air at 80°, above which ventilate liberally, especially on warm sunny days, and close the house for the day at 80°. The night temperature ought to be maintained at 65°, allowing 70° to 75° by day artificially.

Fruiting plants must not further be detained in structures indiscriminately, but should be brought together in a house suitable for finishing the fruit well. Plants that are intended for starting into fruit early in the year should be selected from those that were started last spring, and be arranged, not later than the end of this month, where they can rest for six weeks. Those on which the fruit is swelling must be encouraged with a liberal amount of heat and moisture, keeping the night temperature from 70° to 75°, and that in the daytime from 80° to 90°, closing the house at 85° with sun heat.

THE KITCHEN GARDEN.

Ridney Beans.—Frosts have already injured Runner Beans growing in rather low positions, and if this important crop comes to grief soon then the late Kidney Beans will be all the more appreciated. Water has been needed by the latter lately, and a light moulding up helps to keep the plants unright, and steady. In many cases it would now well keep the plants upright and steady. In many cases it would pay well to board round the breadth of plants and to cover with either spare pit lights or with mats during cold nights. More Beans should also be sown in 9-inch pots, these being filled with rich loamy soil. Place nine seeds in each pot, and put the latter either in a cold pit or in the open for a time, transferring to shelves in forcing houses before cold weather sets in. Sion House is still one of the best for pot culture, but Ne Plus Ultra and Canadian Wonder are also switable. Ultra and Canadian Wonder are also suitable.

Cabbage.—Plants obtained by sowing seed about the middle of July are plentiful and strong, and unless thinned out will soon spoil each other in the seed beds. They may not be much too early, and the first favourable opportunity should be taken to plant out a good breath. first favourable opportunity should be taken to plant out a good breath. The best sites for spring Cabbage are quarters newly cleared of springsown Onions. When the latter are harvested, remove the rubbish and weeds and draw drills 20 inches asunder for the stronger growing varieties of Cabbage, from 15 inches to 18 inches apart being ample for the less vigorous kinds. Water the seed beds and drills a short time prior to planting if necessary. The plants will then draw readily, and may be quickly planted with a dibber. Make the soil firm about the roots, and give a watering. If the ground is ready for the plants prick them out 4 inches asunder each way, and when they touch each other transplant with a trowel to their winter quarters. Club-root, or ambury, is very troublesome in some gardens, and if the plants when drawn are found to have a swelling on the root growths, cut it cleanly off, and then dip in a puddle of clayey soil, soot, lime and water, so as to well coat the root. the root.

Cauliflowers.—Plants from seed sown on a warm border about the middle of August are likely to attain too large a size to winter readily. Pricking them in beds where they can be eventually covered with frames of some kind will check them; but it will be a good plan to sow more seed on shallow beds surmounted by a frame, the lights not being put on much before cold frosty weather prevails. Seed may also be sown on a warm border, the strongest of the plants thus obtained being eventually placed singly in 3-inch pots and wintered in pits and frames. Early Snowball, Early Dwarf Erfurt, Early London and Veitch's Autumn Giant are useful varieties.

Endive.—This succeeds best on warm, light, and not too poor ground. Plants put out now should be located where they can be protected with boards and mats during frosty weather, and should we have a favourable autumn they may yet attain a good size. Leave some plants rather thickly, or from 4 inches to 6 inches asunder each way in

the seed beds, and according as they progress self blanching will take place.

Lettuce.—Strong plants of Black-seeded Brown Cos are very serviceable in the autumn. A few at a time should be tied up moderately tightly, and the hearts will then blanch. Where there are breadths of nearly full grown Lettuce plants of any variety, make some provision for protecting them when frosts prevail. Quite young plants are very much hardier than those nearly full grown. Now is a good time to sow seed of Black-seeded Brown Cos, Hick's Hardy Cos, Hammersmith Green, All the Year Round, and other well known hardy Lettuces on a border

where the plants can remain all the winter.

Parsley.—A scarcity of Parsley proves a source of much worry to a gardener, and every precaution should be taken to guard against failures. The commoner or least curled strains are the hardiest, but these have been largely superseded by more delicate though superior kinds. Strong plants can be rendered hardier and better by being cut over at once, and the crop of young leaves that follow will prove serviceable. Any plants that have not been raised long enough to develop great heads may well be left alone. Before frosts cripple the plants enough should be lifted and either replanted in a frame or pit in good soil, or else in deep boxes or pots filled with good loamy soil.

Select strong plants, pull off the strong outer leaves, and replant somewhat thickly. For a time longer they may be kept in the open, or if in pits or frames uncovered, as it is only during the most severe weather that protection is needed. Branches of fruit trees sometimes afford sufficient protection to save the Parsley underneath when all the rest has been killed. It is advisable, therefore, to form beds or a few circles under some of the moderately low trees by the side of garden walks.

APIARIAN NOTES.

NOTES FROM THE MOORS.

WE are now enjoying beautiful weather, and although most of the Heather is past, there is still much for the bees to add a little more weight to their already abundant store. Two months have elapsed since the bees were brought here, an enormous amount of Heather and Thyme being in bloom; but for the first month the weather was so stormy and of a wintry character that the hives declined in weight, the bees in a great measure getting no more honey than was sufficient to carry on breeding. From the time they were set down until September 4th scarcely a day passed without one or more swarms issuing, and queens are still piping yet. I have proven much, but learned little, although matters are widely different from what is generally taught. These, with other things connected with bees, including Punics, I shall refer to at an early date, which will be both instructive and interesting to be known. I am anyious to get home with the interesting to bee-keepers. I am anxious to get home with the bees, but the great heat in the hives, and honey being still carried in in considerable quantity, preclude the possibility of doing so for some time. The present is the longest Heather season on record.

Bee-keepers will be looking to their own interest if they during this month make sure that queens are all youthful and fertile. Remove all superfluous drone comb, substitute full sheets of foundation, and feed with sugar till the hive is filled with worker comb. Bees winter better on sugar than honey, so bee-keepers have the option of securing more honey and healthier hives.

Pollen—Bees Flying.

I have been much interested at seeing the bees break the rule of gathering pollen from one sort of flower or grass only. I have witnessed them frequently work alternately on different species of both flowers and Grasses.

Some years since I gave my observations and opinion upon this subject to the effect that bees were guided to their hive by possessing a knowledge of the points of the compass, and not that of any land or other mark. I have for some time past been giving the subject more thought and attention, and my opinion is that magnetic influence is the principal guide of the bee, both outside and inside the hive, and that the eyes are of most use to the insect in her flights in the field, and that their antennæ regulate every movement.

THE AGE OF THE BEE.

We have had this subject so often under consideration that it is almost useless to say a word more upon it to refute the erroneous impression that bees live about six weeks only, were it not to point out to bee-keepers that these strong colonies are the result of having two queens' progeny living at one time, not by art, but by a natural act of the bees changing their queens without swarming about midsummer. The bees are still further preserved by being kept much within doors through stress of weather, and being well found in stores the season throughout, being exactly in a similar condition to that which we have so long advised to be done by careful manipulations, and introducing young fertile queens at the proper time.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

P. Barr & Son, King Street, Covent Garden, London. — Daffodils, Hyacinths, and other Bulbs.

Benjamin Soddy, 243, Walworth Road, S.E.—Winter and Spring

Flowering Bulbs.

E. Webb & Sons, Wordsley, Stourbridge.—Bulb Catalogue.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Violas (C. B.).—We are glad to hear that Violas prove so satisfactory in your garden in a large manufacturing town. With deep rich soil and early planting they succeed almost anywhere where flowers can grow. Your letter shall be forwarded to Mr. William Dean.

Exhibiting Celery (Cymru). — You ask if in a collection of vegetables, no "roots" admissible, Celery would be disqualified. We see so many curiosities in schedules and judging that we cannot foresee what strange things may happen, but we know that Celery is not a root crop, and would consequently be ineligible for the class described.

Stocks for Fruit Trees (R. Smith).—The sentence you quote appears incomplete. We understand by it that maiden Apple trees may be had and grown on both the Paradise or Crab stocks, Cherries on the Mahaleb. Paradise stocks, as you probably know, have a tendency to subdue vigour in Apple trees, and the Mahaleb is supposed to have a similar effect on Cherries. The Crab is promotive of free growth in Apples.

Spraying Machine (J. C. C.).—The knapsack pump Eclair with a Vermorel spraying nozzle is an excellent apparatus for distributing the copper solution and Paris green mixture, and is sold by Messrs. Charles Clark & Co., Windsor Chambers, Great St. Helen's, London, E.C., who have advertised the Eclair in our columns. Spraying fruit trees for the prevention and destruction of fungal and insect pests is far less practised in this country than on the continent and other countries, and several crops suffer in consequence.

Transplanting Dicksonia antarctica (J. C. C.).—The plant may safely be moved, just as growth starts in the spring being a good time; but with care they may be successfully transplanted now. Plants in rockwork usually move with a compact mass of roots. With these placed in firm soil, kept duly moist, and the stem syringed, the plant will suffer little from the removal. We have found such plants improve after removal because of new roots having fresh compost to ramify in. We have also known plants cut off at any desired point above ground, and the stems well and firmly inscrted in good soil grow freely and satisfactorily.

Sweet Peas and Asters (A. E.).—It is only in the deepest and best soil coupled with early sowing that Sweet Peas have proved even moderately good this year in the South of England. Asters also need rich moist soil for full development, and, considering the season, the blooms you send are quite as good as could be expected from plants in "cloddy soil." Under more favourable conditions you may expect to have blooms quite up to the market average, but you should endeavour to have them above the average, in fact as good as it is possible to produce them. There is always a demand for the "best" of everything when relatively inferior produce is a drug in the market. Your soil must be brought into a good state of mechanical division, then when it is also enriched it will grow Sweet Peas and Asters well.

Chrysanthemum Leaves Infested with Mildew and Thrips (Amateur). — The leaves not only have been but are infested with mildew, the brownish spots being due to this cause where the fungus has been arrested in growth but not destroyed by the bisulphide of calcium solution. This has probably been too weak, or the leaves may have been damp when it was applied, otherwise it is a specific for the ordium stage of the fungus. It would be desirable to repeat the application for the destruction of the mildew. The only insects we can find on the leaves are the larvæ of thrips, and they are not red but yellow. The perfect insects are not present. They have, however, been on the leaves, for there are several pupa cases, from which they have emerged at no distant date. There is no trace of eggs, so that the present generation being destroyed the plants may remain clean. Dusting with tobacco powder is a good means of keeping Chrysanthemums free from insects and mildew, the tobacco being fatal to aphides and thrips, and the sulphur it contains to mildew and red spider. Anti-blight powder has also been found to keep the plants clean. It would be better known and more largely used if more generally advertised.

Roses and Liliums (F. J.).—The Rose leaves are infested with the black fungus. Burn all the leaves and prunings, and apply a fungicide early in the season. Roses in poor dry soil, or exhausted with age, are more liable to fungoid infestation than are healthy and well-grown plants or bushes. Liliums are usually repotted annually, after the stems have died down in the autumn, removing the old soil and dead fibres, but not the white fleshy roots, the pots being plunged over the rims in cocoa-nut fibre refuse. Many are plunged in cold frames, but more in the open on a thick bed of ashes, provision of some kind being afforded for throwing off heavy rains. We have seen fine Liliums, however, grown without repotting, but simply removing some of the old and adding fresh soil, following with rich top-dressings and liquid support in summer. Under this treatment the drainage must be in an efficient state. Why not try both methods, and thus gain information of the most practical kind? but we should repot the majority of the Liliums.

Apple Benoni (D. E.).—Though you have not seen any mention of this Apple in our columns previous to last week, it has been mentioned all the same and figured. Perhaps you are a comparatively new reader. We reproduce the illustration. The fruit was grown at Chiswick, and the following remarks accompanied the figure:—"The crop was one of the best, and the tree is one of the healthiest growers in the collection, being upright in habit, and hence well suited to borders in gardens. Mr. Barron regarded it as one of the best varieties for following the summer Apples such as Mr. Gladstone, Red Astrachan, and others, and preceding the regular autumn Apples. The quality of the Chiswick

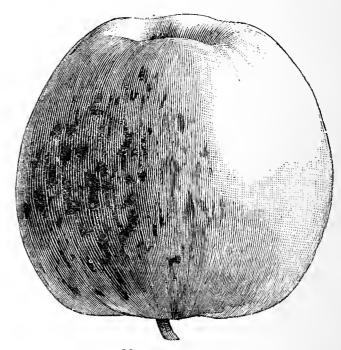

FIG. 33.—APPLE BENONI.

fruit was good, pleasant, and refreshing, but we have tasted fruits richer from Sawbridgeworth, while in Kent we have heard the variety is not regarded as superior. Soils and circumstances have their influence on fruits; but, generally speaking, Benoni may be regarded as a September Apple well worth growing." It is an American variety, and was introduced to this country by Mr. T. Francis Rivers.

Amateurs' Classes (Richard Powell).—According to this definition of an amateur—"A person who cultivates a garden for pleasure and not for gain"—neither of the men to whom you allude was eligible to compete in the amateur classes, as both of them worked for wages. There is another broad distinction in the schedules of some very large shows—namely, that all persons who are not nurserymen are regarded as amateurs, but this is rarely if ever the case in connection with local exhibitions. Why one of the men whose occupation you describe was admitted and the other excluded is a question beyond the power of ordinary intelligence to explain, and we can only refer you to the extraordinary intellects in your locality.

Timber Measurement (M.).—Procurc "Hoppus's Measurer," F. Warne & Co., Bedford Street, Covent Garden, London, it costs two or three shillings, and you would probably find "Nesbit's Practical Mensuration," 3s. 6d., "Key," 5s., useful; it is published by Longmans, 39, Paternoster Row, London, E.C. You ought by aid of the Hoppus to readily master the measurement of timber. In measuring for sale do it yourself; we have more than once detected buyers of timber making mistakes in the girth. The value of timber is very much a local matter, and you will do well first of all to thoroughly master its measurement and then attend a few timber sales to acquire some knowledge of its value. Coppice or underwood also vary according to locality. We have sold Ash and Chestnut in Kent for hop poles for £40 an acre, but the price has fallen of late years. We have also in Sussex sold Oak and Hazel copse wood for £3 and £4 an acre. So you see the range is a wide one. This is a matter requiring full knowledge of local requirements, of markets, and of the purposes for which different sorts of wood may be used. No book would give you such information.

Grape and Rhubarb Wine (J. M. L.).—A very good wine can be made from Grapes which do not attain their perfect maturity in the open air in this country. The fruit should be allowed to hang as long as it is likely to derive any benefit in the way of ripening, and when it is ready the bunches are to be gathered and laid carefully, so as not to bruise the berries. The berries are to be picked separately from the stalks, discarding all that are in any way decayed. Measure the fruit as it is put into the fermenting tub, and to every 15 gallons of fruit add 1 gallon of soft water. Stir and bruise the fruit, and after standing for twenty-four hours, strain and press the fruit through a hair cloth or coarse canvas bag, subjected to pressure. Now test the liquor by the succharometer and bring up the gravity to 120 by the addition of sugar, every pound of sugar raising the density 35 or 36. Let the whole be well stirred, and add 1 oz. of argol to every 3 gallons of must. Stir the must every day, morning and evening, and when the density falls to 80, and the fermentation becomes languid, the cask is to be bunged up, and the wine bottled off in the month of March following. Rhubarb wine is very palatable, but as it contains exalate of lime it is injurious to some constitutions, and should not be regularly used without consulting a medical man. To make 10 gallons of wine take 60 lbs. of the stalks of the leaves of Rhubarb unpeeled. Cut these in pieces and bruise them with a mallet, or pass them between rollers such as a wringing machine without cutting them. Put them in a fermenting tub, and pour 5 gallons of cold water over them, leaving them to macerate for twelve or sixteen hours; then press the whole, returning the juice which has been expressed to the fermenting tub. Add 30 lbs. of sugar, or as much as is necessary to raise the gravity to 110 if a sparkling wine is desirable, and to 120 if a still wine; also 4 ozs. of powdered argol, and enough water to make the quantity of liquor up to $10\frac{1}{2}$ gallons. Cover the tub with a blanket and place it in a temperature of 55° or 60°. Stir it occasionally for three days to encourage the fermentation, and then strain it through flannel into a cask, which must be kept full to the bung till fermentation ceases. As soon as the gravity of the wine is reduced to 40 the cask may be removed to the cellar and the bung fixed firmly in. In a month or six weeks the wine may be fined, and drawn off into a clean cask or returned to the same one after being properly The cask may now be finally stopped close and left till the time of bottling. If a sparkling wine is desired it must be bottled in March following with the corks safely wired; but if a still wine it should remain in the cask at least a twelvementh before being bottled. In the absence of a saccharometer you must be guided by your judgment in the procedure, but an instrument can be had for about 3s. 6d. from Messrs. Cetti, Opticians, Brook Street, Holborn, London.

Names of Fruits.—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. Smith).—A, Brockworth Park. The others not ready for naming. You should attach the number more securely, or wrap each specimen in paper, with the number, not a letter, marked inside. (F. J. Gray).—1, Gloria Mundi; 2, King of the Pippins; 3, Northern Greening; 4, Winter Greening; 5, Sturmer Pippin; 6, Blenheim Pippin. (Richard C. Long).—1, Gloria Mundi; 3, Striped Beefing; 6, Greenup's Pippin. The others too imperfect for naming. (W. Strugnell).—1, Maréchal de Cour; 2, Althorp Crasanne? 3, Easter Beurré; 4, Beurré Sterckmanns; 5, Beurré Capiaumont; 6, Beurré A. Lucas. Graft the trees of all those of which you have sent a list; they are worthless. Pears cannot be named with certainty when they are quite green and hard. (A. H. L.).—1, Louise Bonne of Jersey; 2, Maréchal de Cour; 3, Gravenstein; 4, Duchesse d'Angoulème; 5, Margil; 6, New Northern Greening. Pinning numbers in the eyes of fruits is a very bad practice. (P. Morris).—1, Emperor Alexander; 2, quite decayed; 3, Yorkshire Greening. (F. Jellico).—Lord Suffield; very fine. (W. Spencer Payne).—69, Keswick Codlin; 70, Baldwin. (James Smart).—1, Court Pendu Plât; 4, Small's Admirable; 6 and 9, Tower of Glamis; 7, Blenheim Pippin; 14, Coe's Golden Drop. (J. S. B.).—1, Nouvelle Fulvie; 2, Allen's E

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. M. B.).—Cratægus coccineus. (W. G. S.).—Ranunculus parviflorus, a British plant. We have pleasure in naming plants for regular subscribers. (Cymru).—1, Asplenium flaccidum; 2, Thunbergia alata; 3, Lonicera brachypoda aurea reticulata; 4, Berberis vulgaris; 5, Begonia Evansiana; 6, Summer Savory (Satureia hortensis). (Somerset).—Probably a Solanum, but specimen had only one withered flower; 2, a Pentstemon, but flowers too withered to identify species.

COVENT GARDEN MARKET.—SEPTEMBER 6TH.

WEEDS.

"No one knows the expense of cleaning a foul farm till they have tried it," said a sound practical farmer once, when discussing ways and means for cleaning a dirty farm. Many such farms will be falling in hand this Michaelmas. Entirely are we in sympathy with the landlord, agent, or home farmer who has to take and make the best of them, as has fallen to our lot to do many a time. How any man, but especially a tenant farmer, can suffer land for which he pays rent to become foul with weeds is a matter beyond our comprehension. It is a shameful thing for which there can be no excuse; suicidal on the part of the tenant, harmful to the landlord, and not unfrequently a nuisance to an entire parish, as, for example, in the case of the tenant of a hill farm, whose landlord held him to the conditions of a lease so far as rent was concerned, while the price of corn became ruinously low. The rent was high, the tenant was angry, he foolishly let his land get so foul with Thistles that in the last year of his tenancy they ran to seed among the spring corn in such quantities that in a high wind the seed was blown far and wide over the neighbouring farms.

That farm came into our hands at Michaelmas so dirty that much of it had to be fallowed in the following year, and we were thought fortunate in being able to re-let it after a year of persistent cleaning. Cropping in anything like the regular fashion was out of the question. Ploughs, harrows, horse hoes, cultivators, hand forks, and hand-picking were all brought into action. Couch fires were set going whenever it was possible, much rubbish was carted to heaps and so burnt; by the autumn we had some fair crops of Mangolds and Swedes, and the whole of the land was cleaner and more thoroughly tilled than it had been for many a day. No very close computation of the actual cost was ever gone into. It had to be done, we had several other farms in hand, and were able to spare horses and implements from them occasionally to get through what was nothing else than estate improvement.

It is by no means intended to infer that work thus done was at all thorough and complete. That was impossible. Thistles would be coming from seed for some time subsequently. Worse than Thistles was the Charlock, of which a fresh crop follows every ploughing for years after land is once infested with it. Its seed appears to retain vitality for an indefinite period, in all kinds of soil. A meadow which had been laid down to grass for some ten or twelve years was drained last winter; this summer hundreds of plants of Charlock sprung up over the drains. In dealing with this pest the only safe plan is to destroy every young plant of it upon its first appearance on a farm; once suffer it to mature a crop of seed and its eradication is practically impossible. Much may be done to reduce it by stirring the land repeatedly in autumn after harvest, just waiting long enough each time for the plants to appear, and then shallow ploughing or even horse-hoeing at once. present autumn is most favourable for this and every form of cleaning; not a chance for autumn tillage should be lost, everything else that can be kept in abeyance for it should be. On light land much of the Charlock plant may be destroyed among spring corn by a light harrowing after the corn is well up. This is a critical operation, requiring care and judgment, or the corn suffers. Best of all, for a field foul with Charlock, is to bring it under a six-years course, so that five years out of the six it is in temporary pasture. By using Grasses of vigorous growth, with Clovers in well balanced proportion, and by keeping soil fertility fully sustained, the seeds are very productive, and the disheartening and costly contest with the Charlock is avoided. Here is the mixture which has been found to answer so well in Essex for such pasture :-

On the other hand, when pasture is very foul with Knapweed, Ox-eye, Buttercup, and Yellow Rattle it may become necessary to pare and burn the sod to get rid of the pests. Under good management there is no reason why the land may not then be broken up and relaid down to pasture with a corn crop. Cows will touch none of such weeds, but they may and do eat unwholesome plants which do harm to the milk. Professor McConnell has recently, in the "Agricultural Gazette." called attention to an instance of this at Tawny Hall, Epping, where, in skilful hands, great difficulty has been found all the summer in getting the butter to come. His explanation is so clear and withal so important that we quote it :-- "The excessive drought had rendered it necessary to give the cows access to land which had always hitherto been mowed for hay, and it was noticed that a plant similar to Parsley or Dwarf Hemlock was growing in a portion of this. The cowman recalled to

mind that an old herbalist had told him that this plant would prevent the butter from coming, and it was resolved to try the effec's of shutting the animals out of the parts so affected. The effect was almost immediate, as in a week or so the cream had come back to its normal characteristics. The plant proved on examination to be the Pepper Saxifrage (Silaus pratensis), an umbellifer, and in some of the 'Floras' it is noted as stopping the milk if eaten in a large quantity, and of tainting it if a small quantity is consumed. But it is noticeable that it is not mentioned in any dairy work known to me, while the harm that it does may be enormous. In this case it affected the milk of some seventeen cows all summer in such a way that there was an immense loss of butter, which would not 'come,' and, therefore, was lost in the buttermilk. There was nothing of the nature of a smell or taint, for the butter was first-class af er it was made; but the p'ant seemed to affect the cream globules in such a way as to prevent them from uniting."

WORK ON THE HOME FARM.

Poultry require special attention just now in preparation for winter, and next spring also. As the egg supply falls off, and moulting is likely to commence, old hens must be got rid of. The term is appropriate, for if sold they bring about a shilling apiece; exceptionally good hens may be worth twice or three times as much, but anything like a profit on them is out of the question. The best purpose the home farmer can turn them to is to send them to the stock-pot, beginning this as they cease laying. A word of caution is necessary in this matter to the person in charge of the poultry, that none but perfectly healthy hens Twice in our experience has soup been spoiled by a taint are so used. from unhealthy old hens, heedlessly sent to the kitchen with the foolish notion that anything does for the stockpot. A good home farmer makes a point of seeing that all farm produce sent to the kitchen is sound, sweet, and wholesome. But he cannot always be on the spot, and cooks will send at all hours for articles unordered at the proper time. So far as is possible let the bulk of the household supply be sent in early in the day, a second regular journey being made after the afternoon milking. Send up the order-book with the morning delivery, and while quietly striving to enforce systematic action, avoid friction. Remember before all things to keep the promotion of your employer's comfort and convenience in view, and take especial care always to have a surplus supply of everything—no light matter this, but entirely possible. implies no waste, because all surplus produce can be sold, dealers being only too eager to purchase the excellent produce of a well-managed home farm.

Select pullets from March, April, and May broods for supplying winter eggs, as well as for eggs next spring and summer. Take care to have enough to insure a full supply; keep them apart from the chickens kept for killing for table, so that no valuable birds are killed by mistake. If other breeds or more young birds of any sort are to be purchased now is an excellent time to procure them. There are always plenty offered for sale in the advertisements in "Poultry," and we have reason for entire satisfaction with chickens through that agency. Select also stock hidden poultry consider and trackers and trackers and trackers are the satisfaction. birds of other poultry, especially geese and turkeys. As turkey poults come in for table they are much in request, the best birds being killed first, hence the importance of timely selection.

REMARKS.

REMARKS.

27th.—Fine and bright up to 4 P.M., then rain; fine after.

28th.—Dull early with gleams of sun during the moning; bright 1.30 to 3 P.M., then dull to 5 P.M.; rest of the day fine.

29th.—Bright and sunny throughout; fine night.

30th.—Overcast in morning; sun at 10.30 to 2; then overcast, with some sun at times during afternoon; fine night.

31st.—Spots of rain and dark at 9 A.M.; bright sun at 9.45 and till 5 P.M.; then overcast and spots of rain at 5.25 P.M.; fine evening.

1st.—Rain early (2.30 A.M.), dull at 9 A.M., and throughout until 5.15; then sunny; fine night.

2nd.—Dull early; bright sun at 9.45; fine and bright after; fine night.

Another generally fine week; temperature falling slightly, but still a trifle above the average.—G. J. SYMONS.

As we arrive at the autumn it is well to review the difficulties experienced, the successes noted, and the failures, in some instances so painfully apparent, among vegetable crops during the phenomenal spring and summer of the present year. In doing this we cannot fail to be impressed by many significant lessons which must be fraught with useful suggestions for future elucidation. The difficulty of maintaining a constant supply of vegetables was perhaps never more keenly felt than during June and the early part of July, and although since that time this trouble has not been entirely absent (on account of the comparative failure of some crops which are usually reliable ones), yet the greater variety of vegetables in season during late summer, together with a timely, though only moderate fall of rain, and the refreshing effect of heavy night dews, combined to bring about a vastly improved state of affairs.

Vegetable Marrows have been a more abundant crop than I have previously known them to be. From a very early date they have been in evidence on all sides. I find that plants set in the ordinary garden soil, with no other preparation than that of placing a few spadefuls of rich manure underneath, have yielded far better than others growing on raised beds of manure or leaves. This is doubtless accounted for by the fact that much less difficulty is obtained in keeping the former sufficiently moist at the roots during a season of tropical weather, unless the ingenious practice of a Warwickshire amateur gardener is resorted to—viz., that of watering by means of a syphon, which this year has been constantly working on his Marrow bed. Pen-y-byd is, I think, the best variety to grow for table use, the quality being far superior to that of any other.

Peas have by no means been so good as usual. When mulchings and heavy waterings were resorted to well filled pods resulted; but under the best cultural conditions the season was a short one on account of the arid atmosphere which prevailed for a long period. I never remember seeing so few good dishes of Peas staged at cottagers' shows as during the present season. Sharpe's Queen and Stratagem have proved the most productive with me. Early in the season I had several splendid rows of William Hurst, which is an excellent variety to succeed American Wonder or Lightning. The great advantage of sowing Peas in shallow trenches has been clearly apparent, and wherever cultivators have to deal with a light ground I strongly advocate the adoption of this practice, because when the work is well done a greater depth of soil is obtained than in deep trenches, as well as ample facilities for watering.

Turning to Potatoes, a far more favourable condition of affairs can be recorded. Early crops were somewhat undersized, especially in the case of Ashleaf Kidney. Sharpe's Victor was, however, very early and good in every way, the season appearing to suit it exactly, as during wet summers this variety is not superior in quality unless left in the ground till the tubers are fully grown. Puritan and Snowdrop afforded large clean tubers in succession to those first named. Late Potatoes, when grown on deep, well cultivated soils are furnishing grand crops. The tubers are large, clean, and of the highest quality, there being a marked absence of blotches and other disfigurements so frequently noticed when heavy crops are lifted. It is really a most encouraging sign, as the crops are being lifted, to note how easily they are separated from the dust-like soil, exhi-

biting clean, firm skins without a trace of disease. Satisfaction, Late Rose, Best of All, and Brinkworth's Heavyweight are particularly good. The latter variety will, I think, to a great extent supersede Magnum Bonum on account of its superior quality when cooked.

Where Onions escaped the ravages of maggot during the spring months the crops have been good, the bulbs having ripened splendidly. From an exhibitor's point of view perhaps we have seldom been favoured with such a fine Onion season; deep, rich soil, special attention to watering, and abundance of sunshine being the three principal conditions necessary for the production of gigantic bulbs. For home use I know of none better than Veitch's Main Crop and Banbury Improved White Spanish. These two varieties have with me been highly satisfactory, although our soil is by no means an ideal one for the growth of this crop. It is only by deep digging, manuring heavily, and giving frequent dressings of soot that good results can be obtained.

The early and main crops of Carrots must be mentioned as particularly satisfactory. Early Gem proved well worthy of the high praise bestowed upon it. Early Nantes, which we grew to give a succession of young roots, did not behave well, great loss being experienced through a bad attack of grub, which I find is most difficult to keep at bay when the Carrots are thinned as required for use. The holes thus left where the roots are drawn afford a convenient opportunity for the parent fly (Psila rosæ) to deposit its eggs. Where practicable it is, therefore, better to quite clear a sufficient space at each pulling, even though by so doing a few small roots have to be sacrificed. Too much praise can scarcely be given to Matchless Scarlet. From a sowing made on land occupied by Celery last year we have now a bed which brings out many flattering remarks from visiting gardeners. A gritty, yet rich soil with a fine deep tilth is evidently well adapted to the growth of Carrots. Beetroot on an adjoining quarter has also, notwithstanding the season, made good progress, sound roots of the right size for table being plentiful.

The production of really good Cauliflowers has been a matter of great difficulty. Hundreds of plants which during ordinary seasons might have been depended upon to give good heads, have this year either bolted, gone blind, or provided the cultivator with only puny heads. Early London was a great offender in this 1espect; Walcheren and Extra Early Autumn Giant are, however, now supplying good heads, and the older type of Autumn Giant promises to be fairly good, but rain is at present much needed to assist them. The demand for good Turnips has been a thorn in the side of innumerable gardeners. It is only by watering a portion of the crop regularly that we have been able at times to secure presentable roots. Successional batches of Little Pixie Cabbage have proved invaluable by planting them only a foot asunder, and compact heads have been obtained from a limited space at a time when it was by no means an easy matter to induce the coarser growing kinds to heart. Thought and labour were, perhaps, never in greater demand among British gardeners to enable them to successfully cope with the difficulties of the situation than during the past summer, and I believe thousands will join with me in expressing the hope that their brains and physical energy will not again be so severely taxed for many years to come.

Although the labour of summer has been great, the outlook for the coming winter, as far as garden crops are concerned, is promising. Good crops of roots are ready for storing under conditions favourable to good keeping. Borecoles and Broccoli have made firm growth, which is not likely to be easily injured by severe frosts, should they come. We have had opportunities innumerable for destroying each crop of weeds in a young state, and our gardens ought now to be in a clean and sweetened condition, so that with the timely rains of the autumn and frosts of the winter we may look hopefully forward for brighter prospects if not lighter labours in time to come.—H. D.

AN ENTHUSIASTIC VETERAN.

ALL who know him, whether personally or only by report and through his writings, must admit that he answers to the description of my title, not as a mere fanciful dreamer seeing all things through rose-coloured glasses, but as a downright hard worker whose achievements justify his aims, and whose life work has been productive of results by which the community at large has been

greatly benefited.

As a teacher of horticulture, Robert Fenn was one of that staff of grand old gardeners who in the Cottage Gardener did such a noble pionecr work for its advancement. It was over the characteristic signature of "Upwards and Onwards" that most of his striking and original contributions appeared, and though since he retired from actual practice he has not written so frequently, he is as active as ever, and his occasional notes, too, are as welcome as ever to readers of the Journal of Horticulture. They may be brief, but they are very much to the purpose; so effective was that last one on "Anti-blight Powder" that it brought to a climax the long pending intention of a pilgrimage to Sulhampstead (as our leader has it) by two other gardeners whose claims to be regarded

as veterans also are fairly admissible.

The morning after the publication of that article we were on our way to Cottage Farm; a hearty greeting had we from the writer of it on our arrival at Theale Station. We were soon at the cosy home of our host, giving due admiration on our way to the transparent waters of unpolluted Thames in such striking contrast to the pea-soup-like appearance of it that morning in cockneydom; then we enjoyed the pleasant country lane, with its overhanging trees, and the fresh green herbage of the rich pastures on each side of it. Soon were we among the cider casks and seedling Potatoes discussing a point of practice at almost every step, listening to anecdotes of bygone days, telling us of persistent effort and of many a triumph over difficulties. The raising of seedling Potatoes by the veteran appears now to be confined to the crossing of species, a by no means unimportant matter in view of the possibility of an infusion of greater power of disease resistance. In the past it must have been a heavy matter, involving much labour and almost incessant attention. That it was done, and done well, we know; precisely how has yet to be told. One thing that is clear is that Mrs. Fenn has been no mere silent worshipper of her clever husband; she has worked with him, doing her part and something more, for not only has she tested almost innumerable seedlings, cooking, as she told us, as many as 300 of the sorts on trial in a season, but she has evidently entered with her whole heart into the work, watching the progress of each batch of seedlings, and cheering her husband with the loving sympathy of a true wife. As she came down the garden to us, while we were among the Potatoes, we were listening to the story of how in digging up a certain batch of seedlings one was found apparently with nothing but stem and roots. The roots had been followed to the depth of the digging-fork, "handle and all," quite in the contrary direction to the aspirations of "Upwards and Onwards," who was about to give it up as a bad job, when, as he told us, with the cheering cry of "Dig away, Bob!" from his better half came the incentive to go a bit deeper, with the result of the unearthing of a cluster of Yam-like tubers almost a foot in length.

In the garden we saw among many kinds, all free from disease, such splendid varieties as Eliza Fenn, Lady Truscott, Reading Russet, Reading Ruby, and others. There was no blight and no supertuberation, the foliage supported by short Pea boughs, and dressed with the blight-preventing powders, was perfectly healthy. Not a disease spore had laid hold of it, and the tubers were clear-skinned and ripe for lifting. For four consecutive years has Mr. Fenn kept disease off the Potatoes by the persistent use of the powder, puffing it over the growth from the carliest stages of growth onwards till the tubers are sufficiently mature for lifting. He evidently wants no dates for his dressings; he lives among his crops, and anticipates their wants. Hitherto he has used the bellows for this work; but telling us to wait a bit, he ran off down the garden—yes, positively ran—quickly returning with some powder in a fine sieve to illustrate his remarks about the ease of application of the powder to the surface of the leaves, which he is positive is the only part in danger. Certainly there were his Potatoes without a blemish in tuber, stem, or leaf. Has he not sufficient reason to be positive? More than this, he holds that by the maintenance of the foliage in perfect health there is a more full development of tubers and greater bulk of crop, and he

Surely it will be admitted that Mr. Fenn has devoted his life to a work of national importance by the improvement he has wrought in a staple article of food? He has given us Potatoes which are the perfection of size, form, and quality, which are literally flourballs from the present time till the new Potatoes

come in again. He has improved the old hollow-eyed type out of cultivation, and now, as a fitting crown and finish of his work, he is showing in an easy, simple, and certain manner how to prevent disease from attacking the foliage. He has kept his Tomatoes equally healthy, the foliage being a bright green, the growth vigorous, and the crop excellent. To ordinary attention is added an occasional puffing of powder over the whole of the growth, as being all that is necessary to keep off disease.

Evidently both Robert Fenn and his "Missus" are nothing if not original—that was apparent everywhere, even at table where we were regaled with most excellent fare consisting of home-cured bacon, home-made bread and cider, his seedling Cabbage, First-and-follow-on, of singularly delicate flavour, and above all some superb Eliza Fenn Potatoes. After seeing the ample store of jams, and the barrels of various home-made liquors, we saw the fruit trees mostly laden with a heavy crop of fruit. Both young and old trees of "Pay the Rent" had plenty of fruit upon them, as have several other kinds. The trees are everywhere—in the orchard, plantation, garden, and along the margin of the grass land. Some had been headed down and regrafted, no worthless sort being kept, every tree being known and cared for as an individual. Just so is it with the numerous ornamental trees given to Mr. Fenn by his numerous friends; a watchful eye is kept upon every one of them, and needful attention paid to their requirements.

Of the grass and arable land mention will be made in another Of fruit and vegetables much more might be said, for Mr. Fenn has a marvellous fund of anecdote and reminiscence in connection with his life's work most pleasant to hear, and much of which is worth recording. Quite delightful was it to listen to him, as he unconsciously showed how he is and has been held in honour by good men and true. Perhaps one of the greatest compliments ever paid him was when Mr. Paterson, feeling that his end was drawing nigh, sent him all his untried seedlings. They were carefully tested, and the produce of one of them was sent, after Paterson's death, to his son, with a note to the effect that it was valuable, and should be taken care of. That Potato was the famous Paterson's Victoria. Quaint old Chaucer taught that truth and honour were the essential characteristics of a gentleman. In our friend these high and noble qualities are eminently conspicuous, combined with kindly feeling, earnestness of purpose, energetic action, and-well, just a tinge of enthusiasm; they have made Robert Fenn to be held in general esteem, and a man whom the three pilgrims, in common with many others, are proud to term their friend.-EDWARD LUCKHURST.

THERE were three of us. One a gardener developed into a farmer of a somewhat advanced type, also steward, surveyor, farm and garden instructor, and I know not what besides; one a philosopher who would not wear a collar to save his head, and whose cook I would not be for £500 a year; and one a scribe who was made to feel rather small early in the day. He is getting on in years, and his beard is white, but his head scarcely "turned a hair." The philosopher is just the reverse—beard brown, head white. On his being asked for an explanation of the phenomena he came down a crusher, in the words of an old Scottish divine—"Men with white beards and dark hair work most with their jaws, while men with white heads and dark beards work most with their brains." It was useless for the victim to plead his still tongue as against the philosopher's great conversational power; the farmer shook his sides like a John Bull in ecstacies, and the poor scribe appeared to settle into a brown study, not moving his beard till—well, till dinner time. The philosopher was there too, very much there, and made one wonder why his beard had not turned white years ago. Was it dyed? Now the scribe has had his little revenge he will proceed with his narrative lightsomely and according to the weather.

"Why, the man's writing nonsense!" someone says. Yes, he is; and the man who says so is reading it, though he has plenty of substantial fare all around him. "Oh! I am so sorry you were in the village public house the other night," remarked a good lady to have bother. her butler. To which he replied, "Yes, my lady, I was, the first time for twelve months; but where do you think the gossip was when she saw me there?" If I am told of the shoals of faults in this free and easy communication I shall know somebody has "been there," as the cockney gossips say "a reading of it," for which

purpose it was written.

We met at Westbourne Park—not a lordly demesne, but simply the well-known ticket station of the Great Western Railway. It was a hot day, and the philosopher was found wrapped in woolall wool—for he abhors cotton, and thinks it kills people. On his white head he had a thick heavy dark cloth cap—to draw the heat, most people would have thought. Oh, no! "Woollen cloth keeps out the heat and cold alike, and the body exactly at the right temperature to the fraction of a degree." Happy man! But the burly farmer takes his eye—and fills it; the first meeting after more than twenty years. "Why it can't be the same young man of the old days! yet it must be. But how you've grown!" and then it was a comfort for a quiet man to ensconce himself behind a newspaper in the most far away corner possible to escape the battle of the tongues as they fought out the claims of Potatoes and Tulips, for one of the combatants is great on one, while the other seemed "gone" on the other. This Tulip and 'taty war was continued till the end of the journey, and only ceased when the scribe shouted-"There he is! don't you see him on the platform, in the cream-coloured hat? that's Fenn!" He had come to meet the pilgrims. What a change from the man in wool! Here was our host in his white blouse—indeed white, almost from head to foot, looking as cool as a Cucumber, while he gave to his friends the warmest of welcomes, as is his wont. "And now we have to get home," quoth he. "Here is the cart for three, and the waggonette is coming." The cart seemed to tempt the farmer. It was a genuine country article that had, no doubt, carried many a load of Potatoes, and had a seat across it for three. Away jogged Fenn and the farmer, as happy a pair as the man in charge had ever seen safely set down at Cottage Farm.

There are two ways to Sulhampstead from the station. One over the bridge to the left, eventually skirting the park—"Fenn's coach road;" the other to the right through the village of Theale along the Bath Road to the "Three Kings and Jack's Booth"—a wayside house that marks the turning to our rendezvous. And here was made a discovery. When the farmer left London he had as much thought of seeing the Queen as his sister, but here he discovered her as the happy landlady of "Jack's Booth." No, you have not caught us, Mr. Watchful Reader, as the butler was caught—in the public house. We did not go in with the farmer, but on the return journey waited outside for him like strict TT.'s.

Cottage Farm is a truly rural home two miles from the station. As auctioneers would say, "It stands in its own grounds of 15 acres," a picturesque and fertile little property, which has been greatly improved by Mr. Fenn since he purchased it some fifteen years ago. We enter the orchard gate, and find thrifty well fed trees laden with excellent fruit. By a well contrived system farmyard drainage and sewage are conveyed to the trees by channels cut in the grass, the land gently sloping, and the trees in turns are given a treat. Of one tree of Cox's Orange Pippin its owner is particularly proud. He brought it with him from Woodstock, but before then exhibited fruit from it at one of the Royal Horticultural Society's Shows. Mr. Ingram of Frogmore invariably won with "Cox's," but that year Mr. Fenn was told, prior to the judging, he was going to beat the Queen. "No," he replied, "that will never do; tell the Judges from me that Mr. Ingram must have the first prize." It was so decided, but the money for an extra first was sent to the parson's gardener who refused to be placed before the gardener to Her Majesty; "and here," he says, holding up his hand, "is the result of it"—a massive gold ring that his then employer, Mr. St. John, obtained for him. Then the wearer of it goes on to tell that the raiser of the Apple was his friend residing near Slough, and he pressed Mr. Cox to place it in the hands of Mr. Charles Turner for distribution—a scrap of history relating to the best dessert Apple grown in this country.

The barn is a feature at Cottage Farm—a great gaunt old time wooden structure with a thatched roof. It is a museum of curiosities—a conglomeration of bags, boxes, and tubs with cider and wine-making appliances all round. Apples, Pears, Plums, Brambles, and even the purple-fruited Berberries are all turned to account; fermentation is active in tubs and barrels, and the brewer bustles about to show us his work and ways. As blithsome as a boy and happy as a prince is Robert Fenn in his rare old barn.

But I must cease. The gardener-farmer said he should write something, and we must not both tell the same story, or if we do not tell it in the same way, on the latter point of which there is little to fear. He will no doubt tell about the Potatoes and general crops, and perhaps of the home-grown dinner which the philosopher appeared to enjoy as well as his mundane friends. There is perhaps one thing he (the G. F.) will not think about—the early history of our host himself. It was a happy thought that led someone to ask, after a taste of Berberry port, "Where did you spring from, old fellow, and where were you trained?" "Spring from, why I sprang from Bury St. Edmunds, and I should have bought the jail there awhile ago if there had been a bit more land with it. As for training, I was sent to a jeweller's shop in Kensington, and have snatched fruit from a nursery where the museums now stand. But the jewellery trade didn't suit me, and I didn't mean to have it, so commenced saving my sixpences to run away, and run away I did. I spent a fortnight in the London Docks looking for a berth on board ship, but in a weak moment lent all my money, and have not seen the borrower from that day to this. I was sought after, caught, and carried home; then

packed off to Oxfordshire to look after chickens, pheasants, and other pets belonging to a young gentleman. That was Mr. St. John, who became Rector of Woodstock, and I remained with him more than fifty years, rising from boy to man, becoming gardener, steward, and general factorum, doing everything for him within the rubric."

It seems our old friend made himself as useful as he possibly could in every way until he became indispensable. That is the way to get on in the world. It is said he became more like master than man, engaging schoolmasters and curates. We did not ascertain if this were true; but we did ask if he preached. "No, that would have been out of order; but I read the lessons, and I read them now in church on Sundays." He is, to speak colloquially, "one of the old sort"—a monarchy-man, church-and state-man, and in all his acts a gentleman; given to hospitality, ready to help rich and poor alike. He has tried to do good, and has done good in his day and generation. Such is Robert Fenn, the pioneer in the improvement of the Potato, a worthy member of the community, and one of the happiest men alive. He makes his friends happy too, and his "missus" helps him. There was just one bright link missing from the cottage; rosy-cheeked Alice was not at home. She had crowded the place with jams and jellies, then gone to London for a change.—The Scribe.

CATTLEYA AUREA.

This magnificent Cattleya is unusually fine this season, the continual sunshine suiting it admirably. There can be no doubt a strong moist heat and plenty of light and sun are required to grow this species properly, and it well repays the trouble taken in its culture by the gorgeous flowers so freely produced under these circumstances.

CATTLEYA GASKELLIANA.

This favourite species also is now in full beauty, and it is very valuable on account of its flowering after C. Mossiæ is over. There are some splendid types now in cultivation, many of them coming near to C. gigas in size, and very richly coloured. If the plants are removed to a cooler and drier atmosphere while in bloom it will serve the double purpose of ripening the bulbs and conserving the flowers over a longer period than would be the case if they remained in the house where grown.

ONCIDIUM INCURVUM.

This very distinct and pretty Oncidium is now flowering freely. It is one of the best of the small-flowered species, not unlike O. ornithorynchum in habit, but the blossoms are larger and the growth is rather more robust. The spikes on well-grown plants attain a height of fully 30 inches, and are much branched and very elegantly arched. The flowers are white, freely spotted and barred with purply rose, and remain a long time in good condition. It is very easily grown in an ordinary compost, and a temperature slightly higher than that usually given to cool house Orchids.—H. R. R.

ORCHIDS AT HIGHBURY.

According to a daily contemporary, Mr. J. Chamberlain, M.P., unlike many amateurs of floriculture, has ample means at his disposal for the gratification of his hobby. It is stated that Mr. Chamberlain now has about 5000 plants of all kinds, and from all parts of the Orchid-producing world, and, of course, the number is being continually added to. They fill thirteen of the eighteen glass houses ranged along the side of the handsome yet unpretentious residence. When Mr. and Mrs. Chamberlain are in London a box of beautiful blooms is sent every week for the decoration of their house in Prince's Gate. In addition, two flowers of the kinds best adapted to the buttonhole are sent every day, and it is with one of these that the famous politician generally makes his appearance in the House of Commons.

DISA LACERA.

This has repeatedly been described as the "blue Disa," and generally excites some interest. The flowers are small, of a bluish purple hue, and are produced on a slender scape without leaves. Alone it is not a very conspicuous plant, but associated with others the flowers have a good appearance, owing to their distinct colour, though this is by no means the brilliant blue some might be led to

expect from glowing descriptions given in past times of the blue Disas at the Cape. It has, no doubt, been carefully determined, but several reliable authors mention D. lacera as having white or whitish flowers. A few weeks ago I saw a plant of it in full flower.—Specialist.

AN EXPERIMENT WITH SHANKING GRAPES.

The above heading will no doubt catch the eye of some readers who have racked their brains to find a method for preventing shanking in Grapes. Let me at the outset disclaim any pretension of having solved the problem, because the same treatment applied under different conditions might produce totally different results. The Vines under notice are probably about forty years old, with their roots in a narrow inside border passing to an outside border. The varieties are Black Hamburgh except one Muscat Hamburgh and one Muscat of Alexandria. The house a lean-to adjoins the hall, which makes the use of strong natural manures objectionable. The outside border, originally a deep oblong space filled with fairly good soil and without any separating wall, is joined to a lawn, the latter having about a foot of light soil resting on a bed of clay. A few years ago an attempt was made to bring the roots nearer the surface. The old soil was taken out down to the clay, and a compost of chopped turf, half-inch bones, and old lime rubbish used in its stead, but with no appreciable effect with regard to the shanking.

Last year about a dozen bunches were left unthinned, and these bunches had not a shanked berry in them. It was at once decided that this year's crop should be left entirely unthinned. Anticipating the extra strain such a proceeding would entail on the Vines, steps

were taken to meet it in the following manner.

In the early part of November the borders were lightly forked over, and a heavy dressing of fresh cow manure applied. This was removed in February, and another supply afforded, which remained till the first week in May, when it was taken off and the borders again forked over. From that time till the fruit began colouring, the undiluted drainings of a cowshed were regularly poured on the borders. Tuesday and Friday in each week were the appointed

days for this purpose, and adhered to.

The result of this treatment is a magnificent crop of good bunches with medium-sized berries (no puny stoneless ones), excellent in flavour, but, as might be expected, deficient in colour. Against this defect I may add that they are much thinner-skinned than any Grapes I ever tasted. There are a few shanked berries here and there, but there are also dozens of bunches without a shanked berry in them, whereas in previous years there was not a bunch but was more or less affected by the disease. That dispensing altogether with the scissors has had something to do with the result I have no doubt; but my belief is that poverty at the root is the chief cause of shanking, and after the above experience I am more than ever inclined to agree with the Scotchman's sage remark that "Muck's the gardener."—Thos. Richardson, The Gardens, Simonside Hall, South Shields.

[We should like to hear what some of our Grape-growing readers have to say on this subject. We are inclined to think that Mr. Richardson, who gives such a clear account of his experiments, may, if he wishes, have Grapes free from shanking on thinned bunches in some not far distant future.]

HARDY FLOWER NOTES.

It is with mingled feelings of joy and of sadness that we view our own and other gardens when September has begun its brief course. The sadness comes unwillingly, but we cannot but fear that frost may come suddenly, depriving some gardens of their beauty. We are fain, however, to drink deeply of the cup of true pleasure while we may. Roses have been blooming with a freedom rarely seen; Dahlias of various types have been brilliant in many gardens, and a beautiful band of flowers of many kinds which the florists art has made almost perfect have come and gone. As we look on these flowers we feel constrained to think with gratitude of the good and true florists who have sought to give better form and colour to the wildlings of Nature. Many of our garden flowers have been improved by art. Look upon the old white Phloxes, and compare them with such varieties as Panama, perfect in form and with larger flowers of purest white; or compare the beauty of some of the old scarlet forms with such fine plants as Flambeau or Toreador, and we are forced to admit the gain is great. Nor is there any real antagonism between the hardy flowers fresh from Nature's hand and those subjected to the florists' art; they dwell happily together. The charming Violetta and the beautiful Violas of the present day are welcome here beside such untutored flowers as the little Viola Zoysi or V. biflora. The garden in the autumn has much of interest besides those plants of improved form. All aglow with colour have been the golden composites which are, perhaps, too numerous, but whose beauty we cannot fail to recognise. Sunflowers, from the great flowered annual forms, which one would think were those of which Browning spoke when he said—

"Fancy the Pampas' sheen!
Miles and miles of gold and green,
Where the Sunflowers blow
In a solid glow,"

to the tall, but miniature-flowered Helianthus giganteus or the graceful decapetalus; Heleniums, with charming flowers, graceful Coreopsis, golden Coneflowers, and those Silphiums which prove not true to their name of the Compass Plant; these, with many others of similar hue and form, seem to have revelled in the sunlight of this brilliant year, and as the sun's rays shine upon them they seem

to be returning some of the brilliancy they have received.

Among the most graceful of these Sunflowers is one which is grown under the name of Helianthus Buttaris (?), and which I saw in flower this year again. The habit of the plant is much like that of H. decapetalus, but it is taller in growth, slightly more graceful, and producing more flowers, which are barely 3 inches across. Looking at the plant one was forced to grieve at the fact that unless it could have been shown as a whole its beauty could never be properly seen at a flower show, and thus its graces could not be revealed to the people at large. Another beautiful yellow composite-for, despite some adverse criticism, I am still disposed to claim some beauty for the plant—is Chrysogonum virginianum, a flower not likely to be much seen at exhibitions, and one which, I fancy, one learns to appreciate from seeing day after day in bloom for months together. Here, in a rather low and damp position, and receiving a good supply of water in the dry season, a plant has, for two or more years, become more and more attractive in my eyes. It is neat and dwarf in habit; in some books the height is given as 6 inches, but here it grows to 10 or 12 inches. The leaves are rather ovate and serrated, and the flowers, though small, being barely $1\frac{1}{2}$ inch across, are pretty in colour, being a bright yellow, approaching orange. It is a native of the United States, but I can find no record of the date of its introduction. The free and continuous flowering habit of C. virginianum, blooming as it does from May onward, will always render it acceptable in the garden of hardy flowers.

While the yellow composites are perhaps predominant in the autumn, we must strive to give other shades of colour and other forms of flower to adorn the borders, and, so far as regards colour, the fine blooms of Rudbeckia or Echinacea purpurea are always objects of admiration. It is gratifying to find that it is being increasingly grown, and that wherever seen it is much admired. flowers, which are about 4 inches across, are what one might call a red purple, and are tipped at the ends with a greenish or grey-green colour. This is a defect, but it is possible that this might disappear in the case of some of the plants raised from seed, and it is to be hoped that this improvement may be attained. The leaves are rather rough and slightly toothed, and the plant grows in some cases 5 or 6 feet in height. There seem to be at least two distinct forms grown under this name, and the plant is said to vary much from seed. Any that I have seen may be divided into two varieties, one with broader leaves and petals, and more robust in growth, and Some three another considerably inferior, although very pretty also. or four Echinaceas are in cultivation, but purpurea, or what passes as such, is the one most frequently met with. It thrives freely in any good open soil, and can be increased by seeds or division. More might be said about these desirable plants, but others must have

notice at the present time.

Exceedingly useful in the autumn, and valuable from its contrast in colour and form with the composites, is one of the numerous varieties of the Veronicas—V. corymbosa, which, with its corymbose spikes of deep purple-blue flowers, is extremely attractive and distinct. The name is given with all reserve, as the Veronicas are in hopeless confusion; but it came to me from a Dumbartonshire garden under this name, which is quite applicable. I should, however, be glad if anyone who can recognise the plant from this brief description can give me any further information about it, and correct the name if erroneous. It must not, however, be confounded with V. corymbiflora, a dwarfer species or variety, and one of the most valuable of our autumn flowers for the rock garden. V. corymbosa grows here rather less than 2 feet in height, but in strong soils should grow rather taller. The leaves, which are of the usual Veronica type, are bright green above and slightly downy below. It grows freely in ordinary soil, and requires no care. According to Paxton, V. corymbosa is synonymous with V. polystachia, which, it appears, was introduced in 1817, but whence no information is given. A note on hardy flowers at the beginning of September, when this is written, would be incomplete without at least a passing reference to the simple beauty of the hardy Cyclamen in full blossom on the rockery. Here the marbled foliage and charming flowers of

C. hederæfolium and C. græcum form objects of the greatest beauty. They grow well under the shade of trees or at the base of rockwork, and are benefited by the addition of lime to the soil. No one can fail to admire the grace of these little flowers, drooping their heads from stems uplifted above the marbled leaves. The only depreciating remark that can be applied to them is that the flowers "are small." This is true when compared with the greenhouse varieties of C. persicum; but beauty does not exist only in large flowers, and the modest worth of these hardy "Bleeding Nuns" will endear them to all who grow them.

It has fallen to the writer more than once to speak in favour of the Meadow Saffrons, and once again he would plead for recognition of their value. Early as they have been this season, coming when other flowers were plentiful, they have yet been very attractive in their various forms. The rosy purple flowers of Colchicum autumnale have been far surpassed in beauty by the rose-coloured C. byzantinum, which is almost perfect in form, while this again has been eclipsed by the ruby flowers of C. speciosum rubrum and C. veratrifolium of Tulip-like size; and these, in turn, have yielded to the superior charms of the magnificent C. speciosum maximum, the gem perhaps of all with the exception of C. Sibthorpi, which I have not as yet had the good fortune to possess, but which I hope will adorn my garden another year. Very beautiful, too, have been the double forms of C. autumnale, the rosy purple one forming a charming tuft through a carpet of the foliage of Anemone coronaria, and the double white flowering later and coming into bloom with the beautiful Crocus speciosus, the first of the genus to flower this autumn here.

The earlier Michaelmas Daisies have been for some time in flower, and with other plants have softened the glare of the yellow flowers; while the Kniphofies or Tritomas, which are flowering unusually well in my garden this season, have added variety to the scene.—S. Arnott, Dumfries.

SOFT VERSUS HARD COLD WATER.

I AM sure many readers of the Journal have been waiting anxiously to see whether Mr. Dunn would accept "W. P. W.'s" invitation, and give us the benefit of his ideas, and I am equally certain many must be astounded to read them in the face of present day facts. I would not have thought it possible to find anyone who would dare to advance such a theory as Mr. Dunn's in the horticultural press. I am inclined to think your correspondent has only put forth a small skirmishing party, while his heavy guns are still in the rear. I may perhaps be a somewhat dull reader, but after going carefully over Mr. Dunn's communication twice I fail to find a single point which will hold water. I am one of those cultivators who do believe cold hard water is something more than slow poison to plants, and will now relate a few stubborn facts.

When I first started on my gardening career it was impressed upon me very forcibly never to give Cucumbers, Vines, and plants water which had been taken direct from the tap, but always to make sure it was somewhere near the same temperature as the house, and for that purpose we used to add hot water out of the boiler. I came to look upon this addition of hot water as absolutely necessary, but was destined to change my ideas. Having entered a market growing concern, what did I see? Simply nothing else but cold water being used, and the crops—well, they were far superior to anything I had seen in private gardens. I have seen such results where the plants and trees have only received cold hard water that for a long time past—to adopt a soapy phrase—I have used no other. I do not mean to say I drench my houses during the dead of winter, but after March it is invariably applied to all the plants growing therein. Our Cucumbers are "hosed up" during the summer months every morning at 6 A.M., the borders and whole house from roof to floor completely drenched. We are compelled to use it at this early hour because it comes from the main of the water company, and after the carts commence watering the roads our pressure is considerably reduced. Is the water cold? So cold that one's thumb gets quite numb with it. In the afternoon the houses are drenched through again. This is all the "soft" water the Cucumbers receive. I have never grown better fruit or heavier crops. I have a friend who is obliged to rise at 4 A.M. to get his houses "hosed up" before the water carts start.

grown better fruit or heavier crops. I have a friend who is obliged to rise at 4 A.M. to get his houses "hosed up" before the water carts start.

The Palms grown for market and nursery purposes are all treated to a similar routine in many of our large establishments. I know one very large firm who use the hose at the end of March, and keep using it continuously till the following winter. Even Mr. Dunn must admit the Palms sent into Covent Garden Market are unsurpassed for colour and general appearance. It is very evident some plants thrive a long while on Mr. Dunn's "slow poison." I doubt very much whether the Heaths so largely grown by some firms ever have soft water; their engines pump it into tanks, but the men use it as fast as it is pumped, so it cannot be

exposed to the air for any length of time.

I will now quote an instance of Grape culture. At one of the largest Grape growing establishments in this country, where tons of fruit are grown and sent to various parts of the country, and even to New York, hard cold water is alone used, and there are few Vines cropped so heavily. The houses have to be strutted up owing to the weight of the crop. In this particular instance rain water is not saved, and absolutely no water is given to the Vines but that lifted by engines.

I could enumerate many more instances in different branches where the much despised cold hard water has to be used, and is used most successfully. I entirely differ with Mr. Dunn as to plants treated with hard water looking pale and sickly. I do not find it so. The majority of my Chrysanthemums are watered with the hose, and they do not present the appearance your correspondent would have us believe they do under such treatment. Mr. Dunn's experience with insect pests is also somewhat novel, especially when I remember plenty of Peach houses where the foliage is kept green and healthy by no other means than cold water. I take it I have proved by actual practice that Mr. Dunn is "whimsical," and certainly in my opinion his ideas on the subjects of which he writes are out of date.—J. B. R.

CAMPANULA NITIDA ALBA.

C. NITIDA, or C. planiflora as it is sometimes called, has been in cultivation for more than a century. It is a North American species,

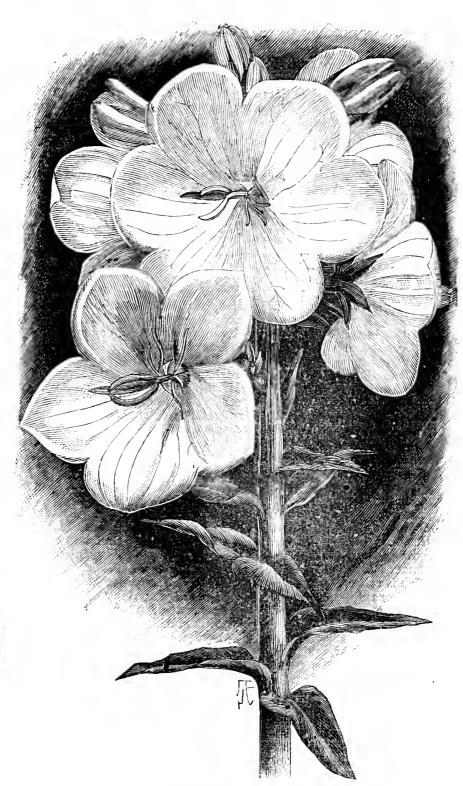

FIG. 34.—CAMPANULA NITIDA ALBA.

and differs considerably in habit and appearance from most of the European species. The short stiff leaves are arranged in dense rosettes. From these rise the spikes, 6 to 9 inches high, of large salver-shaped flowers. The latter, which open one at a time, are about 2 inches in diameter, and of a fine violet colour with a smooth shining surface. The plant is peculiar for the rigidity of all its parts. It succeeds well as a pot plant when grown in a mixture of good loam and leaf soil with a few pieces of soft sandstone intermixed. In many places it can be grown successfully in the open border or rock garden, but some growers have a difficulty in keeping it in these positions. C. nitida alba differs only from the type in having white instead of violet flowers. The illustration (fig. 34) has been prepared from a plant that was recently flowering in the Royal Gardens, Kew.—A. B.

NATIONAL ROSE SOCIETY.

EVERY man has a perfect right to his own opinion, whether he be Mr. Grahame, his anonymous friend, or "E. M." Now my opinion on the Mr. Grahame, his anonymous friend, or "E. M." Now my opinion on the question of Mr. Grahame's circular is briefly this. That the result of the inquiries made in that circular having been published in one of your contemporaries since I last wrote you on the subject, no further correspondence on my part is needed.—E. M., Berkhampstead.

[Nor, we think, on Mr. Grahame's part either, and the present discussion is now closed.]

ROSE THE BRIDE.

ACCORDING to my experience The Bride is a stronger grower than Niphetos, and in some respects a fuller and better Rose. In growth and the construction of its flowers it closely resembles its parent, Catherine Mermet. The greater number of petals in the flower than Niphetos possesses is in favour of its lasting longer, but the flowers have not the pure whiteness of Niphetos. The greenish tint, however, is not objectionable in either wreaths or bouquets. We have lately had occasion to use it for these purposes, and good full flowers are lovely. It will never supersede Niphetos in my opinion for market purposes, for although it is a stronger grower it does not flower so profusely; in fact, it possesses the character of its parent in this respect in a marked degree. -Rosa.

ROSA POLYANTHA (FAIRY ROSES).

THESE charming Roses should be extensively grown if only for their marvellous autumn flowering qualities, for they are particularly bright in appearance at this period of the year. If well treated they make strong bushes, the ends of every shoot being crowned with a profusion of bloom, embracing in their varieties shades of colour varying from pure white to yellow, pink, and deep scarlet. For bedding and massing purposes they are admirably adapted; yet up to the present their qualities in this direction have been overlooked. For forcing purposes, for bouquets or buttonholes, they are also useful, and should be extensively used by persons interested.

The following are the best varieties, yet there are many others well worthy of cultivation:—Anna Marie de Montravel, purest white, well formed; Golden Fairy, nankeen yellow, a miniature Wm. Allen Richardson; Etoile d'Or, canary yellow; Mignonette, soft rosy pink, very beautiful; Georges Pernet, rosy peach; The Pet, pure white, very large clusters; Blanche Rebatel, bright carmine.—J. E. MERRYWEATHER.

A NEW HYBRID ROSE.

A RECENT number of the "Garden and Forest" contained an illustration of a "New Hybrid Rose," with which the following particulars were given:—"In the year 1891 Mr. Jackson Dawson fertilized a flower of Rose Wichweigen with a little of Carlot Toward Towar of Rosa Wichuraiana with pollen of Général Jacqueminot, and in December he planted four seeds which resulted from this cross. The seedlings appeared in January, 1892, were grown in pots during the summer and wintered in a cold pit. All bloomed in June of this year, which is rather remarkable, since few seedling Roses bloom before the second or third year. These plants differ materially, although they all show to some degree the trailing habit of the seed parent. One of them has single pale pink flowers, borne in clusters, and is intermediate in habit between the two parents. Another one bore double flowers of a pale flesh colour, which did not open well, owing to damp weather. The third one has a prostrate habit, with rosy pink flowers borne in clusters of four or five from every joint of its last year's wood. It received a first-class certificate from the Massachusetts Horticultural Society at its Rose Show in June. The fourth plant (which is the one referred to as being illustrated) is not as prostrate in habit as Rosa Wichuraiana, and its broader leaves have a glossy surface. The solitary flowers are very double, and in shape and colour resemble those of Souvenir de la Malmaison, although they are smaller. The plant continues in bloom a long time and promises to be very useful.'

VEGETABLE CULTURE IN ADVERSE SEASONS.

DURING the past two seasons the cultivation of vegetables has been a difficult task, and whilst the struggles with the dry weather are fresh in the minds of gardeners in their efforts to keep the table well supplied with tender produce a few notes on some of the most useful kinds

may be of service. Evidently many gardeners have succeeded in producing first-class produce, judging from the excellent dishes staged at the shows during the past summer, and no doubt equally good vegetables have been grown in various parts of the country and not taken to shows. Gardens lying in low positions have had the advantage of those on higher ground, and in many cases the latter slope as well. In such the retention of moisture is of paramount importance. Exceptionally dry springs, accompanied with cutting east winds, followed by months of drought, are the most unsuitable to the free start of the f unsuitable to the free growth of vegetables. What, then, does recent

experience teach us? I think two most important lessons-namely, the necessity of deep cultivation and mulching.

By deep cultivation I do not mean turning up the subsoil and placing it on the surface, especially where it is of a cold retentive nature, but thoroughly loosening and mixing with it garden refuse, if in a charred state so much the better, and then turning over the surface soil upon it. This, if done when the ground is tolerably dry, during the autumn or winter months, and allowed to remain with a rough surface so that the weather can act upon it, will produce a good seed bed in spring. Never work the land while it is in a wet condition, or the evil effects will be felt during the whole of the following season.

Mulching during the dry months of summer will prove to be of the greatest value. Mulch with manure, decayed leaves, half-decayed straw, or grass from the lawns after mowing; failing these form a dust mulch by continually plying the Dutch hoe between the crops. This is of more value on light soils than continued drenchings of cold water from

POTATOES.

As Potatoes are the chief mainstay of every garden I will deal with them first. This is the proper time to select the seed tubers for next year, and great care should be bestowed upon them. Medium-sized sets are the best, and if placed thinly in boxes or cool sheds, and kept safe from frost during the winter, but given as much light as possible, a good

beginning will have been made towards the next season's work.

The ground will next require attention. If stable manure is to be used apply it in the autumn or early spring, thoroughly mixing it with the soil to a good depth, whether it be light or heavy; but, if heavy, leave the surface as rough as possible. The weather acting upon it will pulverise and make it suitable for planting in due time.

Previously to planting the seed tubers should be examined, and if more than one or two shoots are prominent reduce by removing them to that number. If seed is scarce they may be cut in two leaving one

to that number. If seed is scarce they may be cut in two, leaving one sprout on each section; but I prefer to plant medium-sized whole tubers with sprouts on them a quarter or half an inch long, not pale in colour, but dark green. If the soil is heavy spread over the surface cinders and leaves of any kind. If artificial manures are to be used, sprinkle them in the drills before planting, and a small quantity of dry lime is of service in keeping worms away and the skin of the Potatoes clean. To avoid disease plant in rows 24 inches apart for early and 30 inches for late sorts, the former 12 inches asunder in the drills, and the latter Close planting often means the reverse of a heavy crop of fine tubers. Remove some of the haulm in a young state if any of the roots appear crowded with it. Well ply the hoe between the rows early, and keep the crop clean.

Early sorts may be planted in February if protection can be given from frosts during the first part of May; but the middle of March is soon enough in exposed situations, and not later than the 20th April for late sorts. A change of seed is highly beneficial. All should be lifted and stored during dry weather if possible. Some of the best varieties are Ringleader, Early Puritan, Rivers' Royal Ashleaf, and Myatt's Ashleaf for early use. Second early: Windsor Castle, Early Regent, Snowdrop, and Beauty of Hebron; Triumph, Magnum Bonum, and Clarke's Maincrop Kidney for late use, with Vicar of Laleham as a coloured companion. It is a good cropper and shapely.

PEAS.

This is a very important crop, and a wise selection of varieties must be made, with good ground for growing them. We sow early sorts on warm, sunny borders, midseason and late ones in trenches, not as prepared for Celery, as I think these are usually made too deep. If the trenches for Peas are 8 inches deep in the first instance they will do. Throw out the soil on each side evenly, place in a good dressing of well-decayed manure, and well mix it with the soil at the bottom of the trench. If left in an undisturbed mass, and a hot season follows, the manure dries up, but if well incorporated with the soil it does not. One inch of soil must be placed in the trench afterwards and trod down a little. Upon this sow the seeds evenly and thinly, covering with 2 inches of earth; thus an open trench is left 5 inches deep. In the summer I prefer to cover the seeds deeper. When the Peas are 2 inches high or so, if they appear to be at all crowded, thin them out a little before drawing the soil to each side of the rows. This will prove a good means of support. Staking ought not to be delayed. The sticks should be put in very firmly, according to the height of each variety, not omitting to use a few small branches. If any variety is thought to be behind the time at which produce is wanted, topping the plants will cause them to pod more quickly.

Avoid watering Peas unless it can be constantly attended to. Even

then I doubt its benefit. Better than watering is mulching after a good rain. Leaves, half-decayed manure, or lawn grass should be placed on the surface of the soil on each side of the rows to a depth of 2 inches. There is no question as to the benefit the plants derive from this operation, but it should not be too long delayed, or its use will be of little avail. If the rows are 6 to 9 feet apart, with such crops as Potatoes, Cauliflowers, or Spinach between, the sun acts on both sides, and fuller

crops of Peas result.

There are so many varieties that a good selection should be made. Of first earlies Laxton's Earliest of All, Dickson's First and Best, William I.; of second earlies Champion of England, Duke of Albany, and Royal Jubilee; for late use Veitch's Perfection, Autorat, and Ne Plus Ultra are good. No garden should be without the last named, as it withstands mildew till the crop is nearly all gathered. Sowings may

be made in the autumn, but I prefer to sow in pots or turves in spring and plant out in favourable weather if early Peas are urgently required. Ashes, soot, and lime scattered around the rows in spring will prevent slugs destroying the plants. Mildew is often very troublesome, during a dry summer especially; the best preventive is to sow those sorts which resist it the best, and avoid the use of cold water.—G. GARNER.

(To be continued.)

PARAGRAPHS ABOUT THE PARKS.

REGENT'S PARK.

As most people who have a geographical knowledge of London and its suburbs arc aware, Regent's Park is situated in the north-western portion of the metropolis, and is of easy access from all parts. Visitors from the north arriving at King's Cross, St. Pancras, or Euston Stations, can reach Regent's Park in a few minutes, either by the Underground Railway to Portland Road Station, or by omnibus along the Euston Road. Similarly those who arrive in the metropolis from the south side will find that many 'buses from Charing Cross and the Strand pass this park, in which may be found the famous Zoological Gardens, and also the Gardens of the Royal Botanic Society. The park is a large one, and is a popular resort of many Londoners.

The summer bedding in Regent's Park is always well done, and this year proves no exception to the rule. Some borders and occasional beds may, of course, be found in various parts of the park, but the principal bedding is to be seen near the entrance, a few hundred yards from Portland Road Station. Immediately inside the gates the visitor comes upon a series of beds well filled with plants. Traversing the walk on the right a number of standard and pyramid Fuchsias sunk in the turf in clumps attracts attention, the plants being well grown and profusely flowered. These are usually a feature here, and are greatly admired. Opposite to a group of Fuchsias is a clump of foliage plants comprising tall specimens of Dracæna lineata, Bamboos, Cycas revoluta, and Tree Ferns. Being slightly shaded by trees, these have done well during the past summer, and doubtless imparted a cool appearance, if such were possible, on the oppressive days of August. Last week when I saw the plants they were as fresh looking as when under glass.

A noticeable feature in this park, as it is in others in and around the metropolis, is the excellent manner in which plants are arranged in the beds. Now and then some fastidious person takes exception to certain combinations, but these instances, as they should be, are rare. Taken as a whole the bedding in the London parks is exceptionally well done, and many a gardener might glean a few useful hints by paying an annual visit to them. The plants, moreover, flourish amazingly considering the fact that the atmosphere is not always of the purest kind, and as regards the arrangements but little fault can be found. These remarks apply to the park now under notice, and Mr. W. Jordan, the Superintendent, has cause to be proud of the result of his labours this year.

There are some charming beds on each side of the walk to which allusion has been made. One filled with Begonia semperflorens rubra and Königa maritima variegata and Dactylis glomerata variegata is very attractive and worthy of imitation. A similar shaped bed filled with Begonia semperflorens rosea and Mesembryanthemum cordifolium variegatum is also good. The Begonias are covered with pink blossoms, which form a pleasing contrast to the yellowish foliage of the Mesembryanthemum. By the way, it is noted that the various forms of Begonia semperflorens are used extensively for bedding in all of the metropolitan parks, and for which purpose they are apparently well adapted. These Begonias are likely to prove dangerous rivals to the tuberous-rooted section.

At the end of the walk referred to a large corner bed on the right is noticeable for the manner in which the plants are arranged. The background is filled with huge Palms, over the leaves of which Tropæolums have grown, and are flowering profusely: Near to the front are masses of Lilium tigrinum, standard Fuchsias, Ivy-leaved Pelargonium Abel Carrieri, Begonia semperflorens rosea, and Veronica Andersoni. These plants are placed in bold clumps, which show to perfection their characteristics and adaptability for the purpose. Those persons who are fond of neat, formal combinations would perhaps find little in this bed to admire, but to others who, like myself, prefer artistic arrangements, there is much that is worthy of admiration.

Leaving this corner group and turning to the left more beds of various shapes may be seen: They are all well filled with plants of different kinds, and for the second week in September are most effective. Two beds in particular, however, attract one's attention, these being what a lady would term "lovely." One of these beds presents a fairy-like appearance. It is round in shape, and would remind one of a bride's bouquet had it been raised a little. During the whole of my travels in gardens I have never seen a similar arrangement. The centre is filled with Dactylis glomerata variegata and Lilium lancifolium album, amongst which were plants of Asparagus plumosus, the sprays of the latter giving the whole a light graceful appearance. The bed is edged with a row of Begonia Worthiana, outside which is a ring of deep green Saxifraga. The opposite bed to this, of a similar size

and shape, is devoted to Begonia semperflorens rosea and Königa maritima variegata, from which rise plants of the charming Eulalia gracillima.

The vases filled with flowering and ornamental foliage plants are not the least striking feature in this park. This year these must have caused much labour in watering, but it has apparently been well done, for the plants have made vigorous growth. A huge clump in the centre of the "flower garden" is particularly noticeable. This is perhaps 15 or 20 feet high, there being a very large stone vase in the centre of a raised bed, although this is hidden from view. The vase is filled with variegated Abutilons, Eucalyptus globosa, fine Zonal Pelargoniums, and Grevillea robusta, the sides being draped with Tropæolums, Ivy-leaved Pelargoniums, and other drooping plants. Around these come Palms, Abutilons, huge Zonal Pelargoniums full of bloom, and various other plants, the whole making a striking effect. There are several smaller vases, and these likewise make an imposing display.

Reference should be made to two clumps of succulents, Saxifragas and Sedums, which doubtless interest many visitors. These are formed near two walks and beneath the shade of trees. All the plants, moreover, are named, the labels being well and distinctly written so that anyone might without difficulty ascertain the appellation of any particular plant. The ground in each bed is covered with Sedums and Saxifragas, amongst which S. lactea and S. Aizoides, are conspicuous, and from these rise clumps of Agave americana and its variegated variety, Echeverias, Sempervivums, and other succulent plants. All are arranged with excellent taste, and if less showy than some of the other bads are none the less interesting.

Much more could be said in regard to the bedding in Regent's Park, but space is limited, other parks have yet to be mentioned. A note should be made, however, of the many charming beds of Celosias, which at this period of the year are exceptionally bright and attractive. Lilium tigrinum is also used with good effect in many beds, and the same may be said of other Liliums. Early Chrysanthemums, too, must not be overlooked, and it would be well if these were as extensively used for bedding purposes in private gardens as they are in the parks. They also make a splendid show on the numerous borders, and likewise do huge clumps of Nicotiana affinis and various autumn flowering plants.

FINSBURY PARK.

This is another popular open space of northern London, and is situated close to Finsbury Park station on the Great Northern Railway. Tram cars and 'buses also pass the park by the Seven Sisters Road and Green Lanes, which may be easily reached from the centre of the metropolis. It is much smaller than Regent's Park, but the bedding is always effective, and to Chrysanthemum growers Finsbury Park has long been known. The culture of the Chrysanthemum is encouraged here. A huge glass structure nearly 100 feet in length is now being erected as a show house for the plants by the London County Council. When finished it will be a very fine building, and one in which the plants, of which more than 3000 are grown, will be seen to advantage. For the benefit of the uninitiated it may be mentioned that this structure for the Chrysanthemums is situated near the Manor House entrance, which tram cars from the city and other points pass every few minutes during the day.

Much of the bedding in this park is to be found not far from the Manor House. On entering at this point the visitor is brought face to face with an imposing bed of green and purple-leaved Cannas, Gladioli in variety, Eulalia gracillima, and other plants, the edging being composed of Chamæpeuce, Cineraria maritima, and Begonia semperflorens alba. Near by are several beds devoted to carpet bedding, and the Alternantheras are richly coloured this season. A series of beds of different shapes flank each side of a walk which lead to the right from this entrance, and these are filled in charming manner. Two beds devoted to Begonia Worthiana, pink and white Pelargoniums, with dot plants of Acacia lophantha, and edgings of blue Lobelia are most attractive. It is impossible to describe the pretty effect which these beds produce, and to realise the value of the combinations they must be seen.

Cannas are well employed in this park, and with the addition of Verbena venosa make several simple though attractive beds. Begonia semperflorens rubra is also used with good effect, the foliage being a rich bronzy colour in the open air, which enhances its appearance considerably. A bed planted with B. semperflorens atro-purpurea and variegated Pelargoniums likewise commands attention, and the same applies to beds filled with pink Ivy-leaved Pelargoniums, dark Tuberous Begonias, and dot plants of Grevillea robusta. Fuchsias are freely used in some beds, and in others single Petunias are flowering most profusely. These are easily grown plants, and, as a ru'e, they are most effective during the end of the summer and in the autumn.

In what is known as the "Surprise Garden," from the fact that visitors not acquainted with its whereabouts come upon it somewhat suddenly when near the lake, some good bedding is noticeable. This garden is on the top of the hill, and is surrounded by masses of shrubs, a broad wall passing through the centre. The beds on each side arc similar in shape and size, and are planted alternately with the same

kind of plants. Those at the back are chiefly filled with Cannas, Sweet-scented Tobacco, and other tall plants, the beds near the front being devoted to dwarfer plants and carpet bedding. The latter is very fine, the designs being well worked and the foliage of the plants richly coloured. One bed is so good that it may be individualised. The ground is covered with Antennaria tomentosa and the design made with Alternanthera versicolor and A. aurea nana. The centres of the division are occupied with Dracenas and Grevillea robusta, and there are also dot plants of Sempervivums and Pachyphytums. An edging of Echeveria secunda glauca completes the arrangement, which is most effective.

Other beds in this portion of the park are also specially attractive, and are much admired by visitors. A circular bed of Begonias, Grevillea robusta, and Ageratum is noticeable as being an excellent arrangement—simple though effective. The same can be said of a Begonia semperflorens rubra, Veronica Andersoni, Ageratum, with an edging of blue Lobelia and Mesembryanthemum cordifolium variegatum. Some beds planted with Centaurea candidissima and Verbena venosa are also pleasing in appearance, and one filled with pink Ivy-leaved Pelargoniums pegged down, mixed with Acacia lophantha and Begonias, is unusually showy.

Dahlias are grown in huge clumps, and are flowering well this year, the double forms being particularly good. The borders are very gay with large masses of Portulacas, Phloxes, Helianthuses, Liliums, and other autumn flowers, whilst during the summer the annuals are generally seen to advantage here. On the grass some fine clumps of the autumn flowering Crocuses are noticeable, these being in full flower. Notwithstanding the trying summer Finsbury Park has well maintained its reputation for bedding this year, and the whole reflects credit upon Mr. Melville the Superintendent.—OBSERVER.

ABOUT APPLES AND PEARS.

As there is nothing more important in connection with hardy fruit growing than the knowledge of local suitability, it may be well to say that we are midway between Durham and Newcastle, or between the Tyne and Wear. This also might be noticed, that we are some ten days later than are districts that lie on the southern suburbs of Edinburgh. The years 1891 and 1892 being each cold and wet makes the present year's results of more than average value, as it has proved to us which varieties of Apples and Pears require the least sun to mature their fruit puds. Hereabouts, where there has been failure, it has not been owing to heavy cropping last year, as we were not so favoured, but solely due to weakness in resisting frost or to unripe wood following the previous sunless season.

The Cellini, which I consider the hardiest of all Apples, has once again demonstrated that it knows nothing of bad years. With us this useful Apple is an unfailing bearer. Regarding Lord Suffield, which is frequently alluded to as subject to canker, it is surprising to find how short a distance between orchards evidences this failing. On my place it does remarkably well, whereas with my neighbour, who has a thinner soil with a dry gravelly subsoil, Lord Grosvenor is his continuous sheet anchor. I prefer Lord Suffield, as the fruits are more shapely, and up to the present on my forty sixteen-year-old trees they remain healthy and clean. Stirling Castle is also a great favourite, but, being a tree of slow growth, it not only (like Lord Suffield) requires a free stock but may be planted closer than many others. Of course, both these Apples also do well on the Paradise, but for market growing I prefer the former. This year Potts' Seedling, another sterling variety, has been a failure, and I am of the opinion the failure has been solely due to insufficient sun last season. The more vigorous trees have not only been quite barren but the fruit on those more matured has been much short of its true character. Here Warner's King has failed through the same cause, the trees making far too much growth for bearing after such conditions. Bramley Seedling has likewise had no chance this year, but from what I saw of it at Mr. Merryweather's Southwell nurseries, this most certainly is an Apple that I shall not willingly discard.

Following such a summer as the present these two grand Apples will, I expect, next year amply compensate. After ten years' fair trial I am quite out of heart with Worcester Pearmain, but I am glad to find, with a more congenial home in the sunny south it continues to give satisfaction. It crops far too lightly for market purposes in this neighbourhood. Just noticing that Beurré de l'Assomption, Souvenir du Congrès, Marie Louise, and Marie Louise d'Uccle Pears have done best on the wall, and that the latter with Williams' Bon Chrêtien and the Hessle have done best in the open, I shall at present conclude, leaving a few further remarks on Apples to a future occasion.—Joseph WITHERSPOON.

SCARCITY OF DESSERT APPLES-BENONI.

AMONGST fruiterers in the southern towns there has been for the past few weeks a great demand for good dessert Apples. Quarrendens and Irish Peach were soon over. The last-named is not much cared for, being too soft and not bright enough in appearance. No matter how good in quality an Apple may be, if it has not colour as well it does not meet with favour in the market. Growers for sale have not in the past paid nearly as much attention to dessert varieties as they have to those belonging to the kitchen section. The result is that where really good cooking Apples could be bought for 1s. 6d. per bushel, dessert sorts were

fetching 6s. for the same quantity. A large grower and dealer had to commence selling his Blenheims and King of the Pippins three weeks ago. Even Cellini has been in great demand. All the Worcester Pearmains and Lady Sudeley were snapped up at once. A variety named Nanny Apple meets with much favour. Dr. Hogg describes it as being found about Havant and other districts in West Sussex and the borders of Hampshire. It is an Apple deserving attention; it has a bright cheek and is really good in flavour. Dr. Hogg says it is in use during October. This year it was used in August — another proof of the peculiarity of the season. Pineapple Russet deserves more attention than it receives; it has a flavour peculiarly its own. The tree is a straggling grower, and does not fruit freely until it attains some age.

There is a splendid opening for an enterprising person to plant dessert Apples to follow the earlies and be out of the way of the usual autumn and winter kinds, such as Cox's Orange Pippin. One of the best dessert Apples that I know for filling the blank in late summer is Benoni, the American variety figured last week. With me it carried an extremely heavy crop of handsome fruit. In shape it resembles well grown fruit of King of Pippins, but is perhaps rather broader at the base while it is heavily striped with red on a yellow ground. It was ready to gather this year early in August. The fruit is crisp yet sweet, in fact it has almost all the properties required in a degreet Apple in fact it has almost all the properties required in a dessert Apple. The habit of growth is of the right kind, upright, yet vigorous. It is just the sort to plant numerously in a limited space, and with a prospect of a good return for capital and labour expended.—E. MOLYNEUX.

FERTILISERS AND FEEDING STUFFS BILL.

THE following correspondence has been sent to us on the above measure, and we place the letters before our readers. There are obviously two sides to the question, and both of them important :-

> 30, Wood Street, Cheapside, London, E.C. 21st August, 1893.

SIR,—As Solicitor for the Nursery and Seed Trade Association (Limd.), which was formed for the protection of their trades, I have been requested to inquire whether the "Fertilisers and Feeding Stuffs Bill," which has been before the Standing Committee of Trade, is likely to become law this session, and whether it applies to horticultural manures. If the latter is the case, I am instructed to point out to you that such manures are sold by the wholesale and retail seedsmen, florists, and nurserymen in packets, varying in price from 6d. to £1, in the same condition as they receive the same from the manufacturers of such manures

If the Bill does apply to such horticultural manures as sold in packets, and every retailer is bound to give a certificate according to the first section of the Act, please permit me to point out that the trouble in so doing will be so great that it must put an end to the retail packet trade. I am also instructed to inquire whether it is not possible that the Act can be amended by providing that the certificate by the retailer shall be dispensed with if the packets are sold with the name and trade mark of the manufacturer thereon.

It will be impossible for a retailer of such packets to have them

analysed at his own cost.

I enclose you the names and addresses of the President and Committee of the Nursery and Seed Trade Association (Limd.), and I am requested to ask whether you are willing to receive a small deputation from them upon the subject in question if the proposed Act of Parliament is intended to include horticultural manures. Your reply will be esteemed a favour.—I am, Sir, Your Obedt. Servant, CHARLES BUTCHER.

The President of The Board of Agriculture,

4, Whitehall Place, S.W.

Board of Agriculture, 4, Whitehall Place, London, S.W 24th August, 1893.

No. 23,877.

SIR,—I am directed by the Board of Agriculture to advert to your letter of the 21st inst., addressed to the President on behalf of the Nursery and Seed Trade Association, and in reply I am to say that the President was inclined to view with favour a proposal to exclude sales of very small quantities of horticultural manures, say not exceeding half a hundredweight, from operation of the Fertilisers and Feeding Stuffs Bill; but the general feeling of the Standing Committee, to which the Bill was referred, was so distinctly adverse to any such limitation that an amendment moved in that direction was negatived without a division.

The Board have reason to think that the matter will again be brought forward at a later stage of the Bill, and in that event the matter will certainly command very careful consideration at the President's hands. In the circumstance the Board do not think it is necessary that the Association should be put to the trouble of personal attendance. They are well aware of the importance attached in many quarters to secure such limitation of the operation of the Bill as is above suggested, and the fact that the Association concur in thinking that some such arrangement is necessary will be kept fully in mind.—I am, Sir, Your Obedient Servant, T. H. Elliott, Secretary.

Charles Butcher, Esq., 30, Wood Street, Cheapside, E.C.

[This measure, brought forward by the President of the Agricultural Department (Mr. Gardner), was on Wednesday, Sept. 6th, revised by the Grand Committee of the House of Lords, Viscount Cross in the chair.

Mr. Gardner watched the proceedings. On the motion of the Lord Chancellor it was agreed that the seller of any artificial fertiliser shall state in the warranty he will have to give under the Bill that the percentages of nitrogen, phosphates, and potash contained in the product are "at least" what he has promised. On behalf of the Agricultural Department, the Earl of Ribblesdale proposed a new sub-section giving middlemen the same rights against wholesale dealers as retail buyers will have against them. This was unanimously agreed to, and several minor changes having been made, the Bill was returned to the House.

A DAY AT BUNYARDS'.

READERS of Blackmore in general, and those connected with fruit in particular, are well aware that in the Medway Valley there are many acres of land whereon fruit is grown for the market. Times and manners have changed somewhat since "Alice Lorraine" was written, and it is quite possible that there are no Martin Lovejoys now to be found in that fertile vale, but as good fruit is grown as Martin grew, and there is far more of it. Close to the particular portion of the valley where Maidstone lies are the various nurseries of Messrs. Bunyard & Co., and they are a very remarkable example of the law of development which has affected fruit growing in England. The principal nursery adjoins Barming station on the L.C. and D. Railway. Mention of this line is generally accompanied by a gird at its directors; but I refrain from following the example, not because I have not experienced hard seats and slow time, but because it would be a waste of space. I can only say that if you are going to pay the Allington nurseries a visit book to Barming from Victoria or the City on some Thursday morning when there is an extra attractive number of the Journal to study, then perhaps the weary time will be beguiled and the nurseries reached with the natural sweetness of your disposition unsoured.

Barming is a quiet station, and there is no need for surprise if a visitor finds that he has the whole platform to himself and the entire staff to wish him a cheery good morning (as though he were in the habit of going to Bunyards' every day) and take his ticket. If he crosses the line and passes through a little swing gate he is in the nursery and amongst the fruit at once. I suppose I need hardly say that this is an improvement upon going to Maidstone and having to work back two or three miles by road. This has been done, but never without a profound and comprehensive disgust taking possession of the doer after the truth had come home to him. Before the round of the nursery is completed most people have had enough pedestrianism for a time without tacking on the unnecessary miles. There are now about 100 acres, besides land elsewhere under Strawberries and shrubs. Mr. George Bunyard is an able and far-seeing man. He has kept himself on the front of the wave which has swept ignorance and prejudice before it and taught that good fruit can be grown in our own country as well as abroad. He has built up a huge and prosperous business by sound knowledge, great yet prudent enterprise good work and unwearied perseverance

enterprise, good work, and unwearied perseverance.

Allington without Mr. Bunyard can hardly be called itself, and my visit happened to be paid when a temporary but distressing indisposition prevented him from doing the honours of his nursery. But he has a manager of admirable qualities in Mr. Buss, who is well fitted to take command when his chief is hors de combat. Incidentally I might remark on the good spirit prevailing between employer and employed in the Bunyard nurseries. "I have first-rate men," "We have a first-rate master." Such are the expressions of mutual esteem and respect that are heard; and there is little doubt that the existence of these cordial relations has much to do with the excellent qualities of the trees sent out. Mr. Bunyard has set his heart on supplying the best material, and his assistants do their best to support his wishes.

THE CORDON-STANDARDS.

In making a few jottings of the nursery and its contents, I will draw attention first to a class of tree that has become very popular and grows yearly in favour. "Amateurs' standards" is the term by which the trees are known at Allington. They might be called cordon-standards, in their younger days at all events, for then they combine the two systems. Most fruit growers are aware that the stems of standards on the Crab stock are feathered for a year or two in the nurseries in order to thicken them, and that eventually the shoots are removed. The amateurs' standards here referred to are budded on the Paradise stock, and fruit spurs form on the stems, yielding produce while the head is developing. It might almost be said that stem and head act as a brake on each other. The branches have no tendency to become luxuriant owing to the check imparted by the fruiting of the stem spurs. They develop steadily and sturdily; but when they have gained strength, solidity, and maturity, the brake begins to act the other way, the stem shoots weaken, and eventually they are cleared, leaving the standard with a good head of fruiting branches. This is the theory of the matter, and the practice well supports it. The trees are never staked. There are great numbers of them standing up stiff and straight in different parts of the nursery lined with fruit, and it is not surprising that visitors take to them.

THE "GRIDIRONS."

The Bunyard gridirons are very different articles to those of the ironmonger. They are dwarf trees with two horizontal shoots right and left, from which spring uprights a foot or so apart. These are cordonised, to coin a word, the side shoots being pinched and spurred so as to keep

the trees thin and admit abundance of air. There are plenty of these fruiting freely, the Apples on the Paradise, and the Pears on the Quince, many varieties being represented. Owners of villa gardens would find such trees admirable for forming a dividing line between flower and vegetable quarters, while in larger places they would play the part which espaliers do now in some instances, coming in very useful for the sides of walks, and for filling up blanks on walls. This is an excellent class of tree, not taking up a great amount of room, but giving a little freer play for inherent energy than horizontal cordons.

SOME WONDERFUL MAIDEN PEACHES.

Mr. Bunyard's practical manager takes great interest and pride in his work, but I doubt if there is anything which he regards with greater complacency than a large quarter of maiden Peaches. These young trees, budded last year, have been stopped and have pushed about a dozen shoots each, the whole framework covering a space 3 to 4 feet across and high. They have made wonderful progress, and must have enormous root power. The shoots are very stout and clean, and triple buds are plentiful. It is not easy to credit that such strong planting material could be evolved so quickly, but the facts are there. With good management after planting these could very quickly be developed into well furnished fruiting trees, and that at a first cost almost absurdly low.

THREE PROMISING NEW PEARS.

There were two new Pears fruiting well to which I would call special attention, because from their seasen of maturity, fine appearance, and good flavour they should prove valuable in private, and perhaps also in market gardens. One is called Beurré Mortillet, and I find it referred to as follows in the firm's catalogue of last year:—"Very large; exhibited very finely by Messrs. Veitch at Crystal Palace Show, 1890; not yet proved; very handsome." It is proving to be an acquisition on trial. It is ready in September and October, and has excellent quality. The fruit is very large and richly coloured; it is peculiar in appearance, having very prominent fleshy folds at the stalk. But the second novelty, Marguerite Marrillat, is still more promising. It is also, 1 understood, a continental variety, introduced by the Chelsea firm. It is ready now, and is very luscious and melting. It is very large, heavy, and brightly coloured, ridgy, and uneven in outline. The variety bears freely, and makes a fine cordon. It will be surprising if this does not become a very popular Pear. It is finer in appearance than Williams' Bon Chrêtien, and does not "go" like that favourite sort. A third Pear novelty worth mentioning is Dr. Jules Guyot. This has a Williams' look about it, but is claimed to be an improvement on Bon Chrêtien, being larger, finer in appearance, and free from spotting.

THE NEWER APPLES.

I may as well begin with Bismarck, for if I did not I should soon drift into it. There is one stretch of about 2000 which is very impressive, the trees being vigorous and healthy, merging naturally, as is the way of this grand variety, into a pyramidal habit. The planting bushes are very fine. There is plenty of large and richly coloured fruit, but a great deal of it has been almost cooked by the excessive heat. Lady Sudeley is conspicuous by its upright, stay-at-home habit, and by its peculiarity of bearing towards the tips of the shoots, requiring hardly any pruning, merely thinning. It has borne its beautiful fruit well this year. Wealthy is grand both in size and colour. A seedling of much promise has been raised by crossing Cellini and Blenheim. It has large fruit of the well-known Blenheim form and full of ruddy colour. Young bushes are cropping well, and the fruit, I was informed, keeps till after Christmas. Of another Apple which is under trial much cannot be said at present. It is a Tasmanian, sent over by a brother of Mr. McIndoe. It resembles Grenadier in growth and Bismarck, so it is said, in fruit. It is so precocious that according to report it bears well on wood of the previous year. Well, we shall see. May it realise the rosiest anticipations, and prove to be another Bismarck.

THE OLDER APPLES-TREES AND FRUIT.

The firm showed at the Agricultural Hall what splendid exhibition trim they are in this year, and they have some magnificent fruit still to come. I am going to say a word about some of the most popular sorts, here referring to the tree, there to the fruit. One batch of two-year-old Potts' Seedling, 6 to 7 feet high and furnished with stout side shoots, numbers about a thousand, and there is about the same number in a quarter of Gascoyne's Seedling, standards, with fine heads developing. Of standard Bramley's there are about 3000, all excellent trees, and it is interesting to note this grand orchard variety fruiting very well in a young state on the Paradise, but it will not do this on some heavier soils. Two-years-old Yellow Ingestries—or Summer Golden Pippin as it is called in Kent—is largely grown both as a bush and standard. There are thousands of Ecklinvilles; this is not the great Irishman's best year, the fruit being scabbed and specked, but our Kentish friends know its great merits too well to desert it. Pyramidal Grenadiers are grand trees, and the fruit is enormous in size as well as being perfectly clean. As grown at Maidstone it is a high class Apple.

Lane's Prince Albert only needs mention, for it is invariably good, but planters should not ask for this as a standard. It is naturally suited for bush culture and to get it up is worked on the Goff. Colonel Vaughan is fruiting finely as a cordon. The fruit is of unusual size, beautiful in colour, very juicy and refreshing. It is a dessert variety worth growing. Frogmore Prolific is in admirable order, and so are New Hawthornden

and King of Tompkin's County. Mention of the last two reminds me how widely they differ in their adaptability to cordon culture. New Hawthornden, with Grenadier, Lord Suffield, Stirling Castle and others, make admirable cordons, but the King will not stoop to so modest a position. Cox's Pomona and Baumann's Red Winter Reinette display the most brilliant of colours. Two high-class dessert varieties which ought to be better known are Rosemary Russet and Egremont Russet. The former comes in with Sturmer and has delicious flavour, while the latter has soft yellow flesh of very agreeable quality. Worcester Pearmain is in magnificent condition. There never seems to be enough of this variety to meet the market demands, and 8s. a bushel is the tempting return which two well-known growers have received. Market men are taking this hint and planting extensively. Golden Spire, Queen Caroline, Lord Derby, Mère de Ménage, and Washington form an excellent quintette to finish with, and all are finely represented. Of the last named, with its beautiful appearance and good flavour, there are some splendid pyramids and it also succeeds as a standard.

STOCKS-MANURE AND WEEDS.

There have been some complaints of the stocks not doing well this year, but, despite the drought, those at the Allington Nurseries are in splendid condition. The Nonesuch has done better than the English Paradise. There is a piece of 35,000 recently budded that forms a striking sight. The ground is well fed. A great deal more value is attached to cloth bits (not shoddy) than most people would give, and a far higher price is paid for it than the majority would be inclined to part with. It is a sustaining and lasting manure. As to weeds, Mr. Buss's proud claim that a barrowload could not be found in the whole 100 acres was readily admitted. The land is thoroughly clean, and the whole place in admirable order. Good soil, kept free from weeds and judiciously fed, is one of the secrets of Mr. Bunyard's extraordinary success.—W. P. W.

[Mr. Bunyard has sent us very fine samples of Kentish fruit, with others of the same varieties grown under less favourable conditions. The former may be taken to represent profit in fruit culture, the latter the reverse—the produce it may be expected of exhausted trees that cumber the ground.]

SUBURBAN SPARROWS.

"DAVIES DUFFRYN" (page 214), wishes to know how sparrows behave in the suburbs of towns. The cheeky birds in my garden are quite opposite to those in Mr. J. Witherspoon's. His sparrows appear to be pets, but mine are decidedly pests. They eat, or pull in pieces, what they ought to leave, and leave untouched what they ought to eat. They appear disgusted with caterpillars, and to have no taste for aphides. They attack yellow Crocuses voraciously, and either do not like to see two flowers open at the same time, or prefer seeing the petals littered on the path. It is the same with Primroses, which the scavengers will not let alone.

They play havoc with the buds of fruit trees of all kinds—"a worm in them!" say their sentimental friends. So far as I am concerned it might as well stop there as the buds be torn off; but I do not believe in this worm theory. It seems a handy refuge for the destitute who do not know what else to say. Were there worms in the Crocus petals?

I bought four dozen young fruit bushes about ten years ago, and have certainly not had 4 lbs. of fruit from them during the whole of that time. If the scoundrel sparrows do not tear off all the buds in spring they take all the fruit that appears long before it is ready for use. It is wrong and cruel to shoot the birds, say their warm defenders, and fruit should be netted against them. Then is it not wrong to deprive them of food and starve them to death? I should prefer to be shot quickly than starved to death slowly; but we cannot shoot in small suburban gardens, where the sparrows appear to be alike masters and scourges.

They take away filth, says their champion. Are flowers and fruit filth? These they assuredly take or destroy, and they do not interfere with caterpillars and insect pests. Mr. Witherspoon is no doubt a very clever man, but he clearly does not understand suburban sparrows, and if he had them to deal with I suspect he would not care in the least

who diminished their numbers.

There are also, as I know, thousands of sparrows not of the caterpillareating kind in the country, but they devour Peas and grain voraciously, and strip fruit trees and bushes of buds. They are an intolerable pest in many places, and a price has to be put on their heads. Even bird lovers and humanitarians who see this depredation of the shoals of birds raise no protest against the practice any more than they would against killing rats and mice if they did half so much mischief as the sparrows.

If these could be evenly distributed all over the country there might be less to complain about, but I am inclined even then to imagine that a number could be disposed of with advantage. I have read somewhere of a happy time when every rood of land maintained its man, and am inclined to think that one sparrow to the rood would be ample, and that one could be very well dispensed with. My unfortunate share is approximately about 200 to that extent of land, and I should be well pleased for Mr. Witherspoon to have the whole of them if I were sure they would change their tactics with the change of scene, or under the good influence of his well-behaved pets, for I do not wish him any harm.

—An Afflicted Suburban Amateur.

THE WEATHER IN LONDON.—Fine dry weather still continues in the metropolis and the south generally. Saturday last, however, was decidedly cooler than it had hitherto been for several days. Since then the nights have been rather cold. At the time of going to press it is bright and clear.

- DURHAM, NORTHUMBERLAND, AND NEWCASTLE HORTI-CULTURAL SOCIETY. — We are informed that the officials of this Society sent a beautiful wreath on the occasion of the funeral of Lady Armstrong, at Rothbury, on the 6th inst. Mr. Elliot and Mr. Bertrand, Lord Armstrong's head gardeners at Jesmond and Cragside respectively, were among the chief mourners. Lady Armstrong took great interest in gardening, and possessed considerable knowledge of plants and their culture.
- Honours to a French Horticulturist.—We understand that Mons. Edouard André has been appointed as Chevalier of the Order of Leopold. M. André is a landscape gardener, a traveller, a botanist, a Professor in the National School of Horticulture at Versailles, and one of the editors of the "Revue Horticole."
- —— REV. LEONARD BLOMEFIELD.—The death of the Rev. Leonard Blomefield, who was the oldest Fellow of the Linnean Society, took place recently. Mr. Blomefield was in bygone days known as Leonard Jenyns, he having assumed the name Blomefield at a later period. Mr. Blomefield, who was elected a Fellow of the Linnean Society so far back as 1822, was ninety years of ago at the time of his death.
- AN INTERNATIONAL EXPOSITION, it is stated, will be held in the city of San Francisco, State of California, beginning on January 1st, 1894, and continuing for six months. The classification will include Department A—Agriculture, food and its accessories, forestry and forest products, agricultural machinery and appliances, horticulture, viticulture, and pomology. Mr. M. H. dc Young is the Director-General and President of the Executive Committee.
- —— CHEAP APPLES.—Fruit is said to be so plentiful in Lincolnshire this year that growers are experiencing the greatest difficulty in disposing of the produce of their orchards. The markets are so glutted, especially with Apples, that the sales in many cases have not realised sufficient to pay the expenses of sending to market. Plums also have been a bad trade, and those that were damaged at all by wasps have been practically rendered unsaleable. The average price of Apples is about 2d. per stone. This, however, applies to inferior fruit; the better samples realising fair prices.
- PANSIES.—Is it generally known how rapidly Pansies reproduce? I broke up an old bed a fortnight ago, and made a new one with the seedlings I found in it. Some of these are already in flower, and the bcd promises in another fortnight to be a mass of bloom. Of course they have been having as much water and almost as much sun as they could possibly require.—A. C.
- —— CHEAP MUSCAT GRAPES.—It is stated on good authority that fair samples of Cannon Hall Muscat Grapes were sold in a fruiterer's shop in the metropolis the other day for 8d. per pound. The Grapes had been grown in Jersey, and although the bunches "were rather small," it is said that the berries were large, "the colour fairly good, and the flavour well developed."
- IMPROVING THE QUALITY OF FRUITS.—Nothing is more common, in conventions of fruit growers, than to hear one man say of a certain variety that it is tasteless and worthless, while the following speaker may laud that variety as one of the highest flavour and best quality. The truth is, says "Mcehan's Monthly," that ripening fruit is an art, which is only to be learned by intelligent experience. Some kinds of fruit require to be gathered a little before ripe, in order to produce the highest flavour, while others require to be dead ripe on the trees before they are gathered. Again, to get the best quality some require to be ripened in a dark and cool place, while others require a warmer and lighter situation. All this has to be learnt by experience, and one of the pleasures of amateur gardening is to study these points, with the view of the production of the best class of fruit.

- GARDENING APPOINTMENT.—Mr. R. Griffiths, from Glewston Court Gardens, has been appointed gardener to Miss Bernard, Over-Ross House, Ross, Herefordshire.
- PLUM CULTURE IN CALIFORNIA.—Some people in this country have but a very faint impression of the immensity of the fruit interest in California. Take, for instance, the Plum. One single grower, says the "Hanford (California) Journal," has 544 acres planted with the Prune variety. On this tract alone are 66,000 trees.
- Gardening in India.—It is stated "that Mr. J. M. Henry, for the last fourteen years Superintendent of the Baroda State Gardens, has now been transferred wholly to the landscape department, and will devote the whole of his time to that work, under the direction of Mr. W. Goldring, who remains in England for eighteen months before returning to India to carry out the many new parks and pleasure grounds H.H. the Gaekwar contemplates making throughout his extensive territory for his people."
- Potash and Peach Yellows.—Mr. B. Von Herff, 93, Nassau Street, N.Y., contends that a want of potash in the soil produces frequent and disastrous results to the Peach grower. All diseases or any disease troubling the Peach grower can be found in soils abounding in potash; and, moreover, it is so well known that the manifestation known as Peach yellows, and similar manifestations in many other trees, are produced by root fungus, that there is no need to call in the lack of any mineral ingredient to account for them. When it comes to the question of a good fertiliser for the Peach, kainit or potash salts may take a place among valuable articles. Anything that may aid in checking fungus growth may be useful aside from fertilising properties. Kainit may do this. Even boiling water poured freely around the roots of fungus-infested trees has been found excellent.
- DISEASES OF GLOXINIAS.—In France Gloxinias have been considerably injured by various diseases. The exact nature of the troubles does not seem to be very well understood, as some are supposed to be due to fungi, and others to bacilli. The remedies proposed are not always efficient, but good results appear to follow the use of some of them. The presence of so much disease can partially be explained by the fact that when the young plants are moved from the propagating house to their flowering quarters the sudden change in temperature weakens them and lowers their powers of resisting disease. The change should be made as gradual as possible. Another suggestion, according to the "Garden and Forest," is found in the fact that Gloxinias which are grown in new houses, or in houses before unoccupied by them, are quite free from disease, while their successful cultivation is an utter impossibility in houses which have been filled by them year after year. Great care in growing only healthy plants will undoubtedly soon become a very important factor in their cultivation, for these plants now appear to be the prey of an ever-increasing number of enemies.
- SAND-BINDING GRASS.—The Marram Grass (Psamina arenaria). the seed of which was first introduced into the colony of Victoria by the Government Botanist, Baron von Müeller in 1883, has been proved to be the most effective sand stay ever planted. Practical evidence can be seen of its value in the miles of sandhills now reclaimed by the Marram plantations, sown under the direction of Mr. S. Avery, the park ranger. So complete has been the reclamation of the lands, says a New Zealand paper, that, where a few years ago not a sign of vegetation was to be seen, there now exists a succulent Grass, eagerly devoured by cattle, and growing to a height of 4 feet. Marram Grass is practically indestructible -burning, cutting, or eating off only makes it thrive-whilst in exposed shifting sand it propagates as surely as in the most sheltered position. The Grass for transplanting has been supplied by the Port Fairy Borough Council not only to the Governments of Victoria and New South Wales, but to numerous municipal bodies and private individuals in all the Australian colonies, New Zealand, and Tasmania, and in no single instance has it failed to thrive. The Grass is supplied at the actual cost of digging, packing, and carting to the wharf or railway station, Port Fairy, which does not exceed 25s. per ton. The following directions how to plant Marram Grass have been prepared by the park ranger :-The Grass to be planted in rows at a distance of 6 feet apart, the space between the plants to be at least 2 feet. The depth to which each plant is put into the sand depends on the nature of the sand. If in sand not likely to drift for two or three months, 9 inches will be deep enough; but in very loose and shifting sand the Grass should be placed from 12 inches to 15 inches deep. A "plant" consists of as much Grass as a man can conveniently hold in his hand.

- —— DEATH OF MR. CHARLES VERDIER. Rosarians and others interested in horticulture will regret to hear of the death of Mr. Charles F. Verdier, which occurred a week or two ago. A gentleman who knew Mr. Verdier for forty years writes that "he has died ripe in years and honours."
- —— SPECIES OF OAKS.—According to an American contemporary, "Prof. H. M. Ward states that there are probably more than 300 species of Oaks (Quercus), of which the majority belong to North America, Europe, China, Japan and other parts of Asia. There are none in Africa south of the Mediterranean region, nor in South America or Australia. Some remarkable species are found in the Himalayas, and many in the Malayan Archipelago."
- DESTROYING WEEDS.—Several correspondents have written to "Meehans' Monthly" recently, as to how to destroy noxious weeds. Poison Ivy, Dock, Canada Thistle, and Dandelions are the subjects of these varied inquiries. Intelligent gardeners know that no plant can live long without leaves. If, therefore, a plant is cut off to the ground soon after making leaves in the spring, it is generally destroyed at once; but sometimes another or second growth will appear, of a more or less weak character, and if this is again cut, the plant will surely die. Nothing is easier than to destroy these weeds when this principle is kept in mind. The writer of this paragraph has known a whole half acre of Canada Thistle entirely eradicated by having a boy cut them beneath the ground with a knife early in spring. Very few produced leaves the second time, but these were again cut as soon as perceived, and the result was to eventually destroy every plant.
- ENGLISH CARNATIONS IN AMERICA.—Writing from Wellesley, Massachusetts, to an American contemporary, "T. D. H." says :- The English type of Carnation has failed in every trial here, undoubtedly owing to the marked dissimilarity of climate and also to the fact that in each country varieties suited to a special plan of culture have been selected. In that country the plants are layered in the autumn, wintered in a cold frame, and grown in pots the following season for the next winter's bloom. Here also selection has been in the line of a particular mode of cultivation, but the plant is different and characteristically American. Cuttings are rooted in January, planted out of doors in May, and are in bloom by the second week in July. I recently had the pleasure of seeing a splendid collection of Miss Fisher, white; Hector, scarlet; and Nobscot, scarlet, in bloom and loaded with flower buds, while along with these were another lot of imported varieties layered last autumn, which were very much later and did not look at all promising. There are no good rose-coloured varieties as yet, but two on trial look encouraging. These are Ada Byron and Nicholson. An elegant yellow-flaked variety also promises to be a good summer bloomer. If neatly staked, as these plants were, they make a fine appearance, and at the same time the flowers are kept from injury by heavy showers of
- APPLES IN AMERICA.—The following extract from a transatlantic contemporary will give readers an idea as to what the Apple crop is in America this year: - "The prospective crop of Apples, commercially considered, as indicated by returns of our correspondents for July, will be light, and in many sections a complete failure. The high returns in June from districts then in bloom have been materially lowered for July, the set has been poor, and the drop, still continuing, severe. Thus in Maine and New York the percentages are lowered twenty-two and nineteen points respectively. These States are by far the most important of the eastern Apple district, and failure there makes the sustained percentages of New Hampshire, Rhode Island, and Connecticut of little significance as regards surplus production, though it are also shown in Vermont, Massachusetts, and Pennsylvania. In New Jersey, Delaware, and Maryland a fair to good crop is expected. The percentage in the latter State, however, has been reduced sixteen points by the dropping of immature fruit, and is liable to still further reduction from the same cause. Virginia has sustained her percentage, and will probably have half a crop. In the Ohio Valley and Missouri fruit belt things have gone from bad to worse. The frequency of the word 'failure' in the notes of the correspondents throughout these sections ominously emphasises the exceedingly low condition, as shown by the percentages. Michigan has declined twenty points since the June report. The high condition of Apples in the Pacific coast region still continues, and a good crop is confidently expected. The fruit is dropping somewhat in Oregon, where the decline since June, though slight, has been greater than in Washington and California."

—— PRICES FOR POTATOES.—It would appear that in some parts of the country farmers are obtaining fair prices for their Potato crops. An auction of 150 acres of growing Potatoes was recently held at the Stewponey Hotel, in the Stourbridge district, when 9 acres of Bruce and Magnum Bonum Potatoes realised £17 5s. per acre, these being offered by Mrs. Giles of Ashwood; and 111 acres of Magnum Bonum and kidney Potatoes, belonging to Mr. T. Dorrell of Enville, made £17 per acre; and 11 acres of Magnum and Stourbridge Glory Potatoes, belonging to Mr. G. Elwill, £15 5s. per acre.

- THE EVENING PRIMROSE AS A VEGETABLE.—The "Lyon Horticole" has a long and interesting chapter on the great value as a vegetable of the common Enothera biennis, the very common weed known as Evening Primrose. Though introduced, it says, from America as early as 1614, it has only recently been known as a kitchen vegetable. It says that it is becoming wild in France, and is known by the common name of Donkey Flower. It questions the accepted origin of the name, and contends that the botanical name is rather derived from onagra, and not, as generally supposed, because the roots exhale the odour of wine. From the shape of its roots it is called in France the Leg of St. Anthony. However, it is as a vegetable that we have to do with it. If the seeds are sown as soon as they ripen young plants grow at once, and the plant throws up flower shoots early next year. This is the case with all plants known as biennials; but if we save the seed and sow it in the spring at the same time as we do Salsafy, Parsnips, and similar biennials, the plants make roots only that season instead of flowers. The author of the paper compares the roots with the Salsafy in value. It is stored away for use from November to April. Under good culture, it states, the roots develop to quite a large size. It also states that it is far superior as a vegetable to the recently introduced Stachys from Japan.

- ROOT FUNGUS.—Intelligent raisers of trees and plants must be familiar with the work of root fungus, and with its effects on the foliage. In most cases the result is to turn the leaves from deep green to a golden yellow, as in the Peach, the Norway Spruce, and the White Pine. In the Carnation the glaucous grey green is changed to a sea green, and so on with other things. The rapidity with which the mycelium, or "spawn," as gardeners term it, travels under ground is wonderful. In a bed of Carnations planted out in early spring for removal in the fall to the Carnation house the writer saw a circle containing a few less than 100 plants infected, and which had to be This fungus had started from some half-decayed wood, and then had radiated some 15 feet to the circumference of the circle infesting every Carnation root in its march, and this 15 feet had been all developed in four months certainly, and probably much less judging by the fact that the leaf tint had all been completely changed. Just how the change is effected so as to give the yellows to the Peach, Spruce, Pine, and other plants, is not known. No trace of the original fungus can be found in the woody structure, yet the wood impregnated with some deleterious substance is capable of carrying the disease to other plants by inoculation. But the fact remains that root fungus is the primary cause.—(" Meehans' Monthly.")

- A CROP OF FINE APPLES.—Wells Palace and some part of the grounds are surrounded by a moat and high wall. Against a sunny portion of the latter, and within a few feet of though well above the water, Mr. J. B. Payne, the head gardener in charge of the place. some years since planted several Apple and Pear trees. From the first these trees thrived and fruited well, and I have seen several good crops of fine fruit on them. Apple Peasgood's Nonesuch has repeatedly been very fine, but this year the crop quite eclipsed anything seen on the tree before, and, as far as my experience goes, anything of the kind ever seen elsewhere. Early in August I counted sixty-two fruits on the tree, every one of which were quite equal to taking prizes at leading shows in the west of England. Recently Mr. Payne exhibited twelve of the fruits at Bath, and it may safely be asserted, nothing else in a generally excellent Show attracted so much attention. At one time I saw not less than a dozen policemen discussing the merits of this particular dish of fruit, and the member of the force who happened to be in charge of that end of the tent was quite delighted when a medal, in addition to the first prize, was awarded to Mr. Payne. Those twelve fruits weighed in the aggregate 15 lbs., the heaviest being 16 inches in circumference, and weighing 22 ozs. All, in addition to being large and well formed, were richly coloured. Mr. Payne has good cause to be proud of his production. -W. lggulden.

- School Gardens.—I was much interested in Mr. Wright's article on this subject (page 201). He correctly remarks that it is not a "novel idea," for I well remember thirty-seven years ago the schoolmaster of the national schools at the village of Rocester in Staffordshire. Mr. Jenkins, suggesting to some of us lads that we should make flower borders round the playgrounds. As space was limited and many wished to take part in the work it was arranged that a lad of the "first class" (no "standards" then) should make and keep the portion allotted to him; having his "chum" for assistant. I remember it gave some of us a good deal of pleasure, and brightened up the barren yards during the summer. Nor were the girls forgotten, for we made their borders too. About a dozen of us each had a plot of ground in a field for growing vegetables, but there was not any provision for instruction, so we were dependent for this on our respective "dads." Truly this is very meagre compared with the splendid facilities afforded to the present school boys of Surrey, still it was a step in the right direction; and probably one of the earliest attempts to instil a love for gardening into the minds of the youths of the working class, and as such is, I think, worthy of being placed on. record.—T. S., Henbury Hill.

CLERODENDRON TRICHOTOMUM.

WHEN flowers of this fine hardy Clerodendron were exhibited by Messrs. J. Veitch & Sons, Chelsea, at the recent Agricultural Hall Show they attracted much attention, and the Floral Committee of the Royal Horticultural Society awarded a first-class certificate. As a rule the blooms appear in September, and, as will be seen by referring to the illustration (fig. 35), they are produced in terminal cymes. They are white with a reddish purple calyx, and are fragrant.

Clerodendron trichotomum is native of Japan, and was introduced many years ago, but it does not appear to be generally grown. It is a vigorous growing shrub, frequently attaining a height of 8 feet in sheltered positions. The leaves are dark green and comparatively large, being about 6 inches in length and proportionately wide. This species is sometimes described as a greenhouse plant, but it is quite hardy, and forms a striking feature in a shrubbery at this period of the year.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 12TH.

THERE were comparatively few exhibits at this meeting, and the attendance was not very large. Fruit was, however, well represented, and there were some good collections of Roses and Dahlias. Orchids were likewise fairly well shown.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); Messrs. John Lee, T. F. Rivers, Harrison Weir, G. Bunyard, J. Cheal,

W. Warren, A. Dean, H. Balderson, J. Smith, G. Norman, W. H. Divers, G. Wythes, T. J. Saltmarsh, and J. Wright.

Mr. W. H. Divers, The Gardens, Ketton Hall, Stamford, sent a seedling Peach raised from the Byron Nectarine, fruits medium sized, round in the standard like Green Misnance for the standard greatly and the standard greatly and mottled like Grosse Mignonne, a freestone of excellent quality, ripening several days later than Lord Palmerston. The variety is named Duchess of York. An award of merit was unanimously awarded, another year's trial being thought advisable before granting a first-class Messrs. Robert Veitch & Son, Exeter, sent their new Peach Late Devonian, rather small dark coloured fruits grown in the open air and not in the best condition, some being distinctly over-ripe. No award was made. Mr. J. Miller, The Gardens, Ruxley Lodge, sent dishes of splendid Peaches grown against an open wall, and a cultural commendation was unanimously awarded.

Mr. Walter Weir, Acton Park Gardens, Wrexham, sent bunches of his new Grape Cape Muscat, berries black, ovoid, of good size, and well coloured. It is a very refreshing Grape with a combination of Muscat and Black Hamburgh flavour, and the crackling skin of Lady Downe's Seedling. The seed was received by Mr. Weir from the Cape, hence the name given to the variety. The bunch somewhat resembles Alicante. An award of merit was unanimously awarded, and still higher honours

may be in store if better specimens should be forthcoming.

Mr. J. B. Payne, Palace Gardens, Wells, sent twelve magnificent fruits of Peasgood's Nonesuch Apple, gathered from a tree trained against a cold, damp stone wall supporting a terrace, aspect south-east. The tree has been planted seven years, and covers a space 17 feet wide and 14 feet high. The crop this year was thinned to sixty-two fruits, none weighing less than 1 lb. The fruits sent would much exceed that weight, and were beautifully coloured. No other kind of fruit had been found to succeed against the wall. A bronze Banksian medal was unanimously recommended.

Messrs. W. E. Browne & Son, The Nursery, Wells, sent a dish of very large Apples named Monster Pippin, for a certificate, but it was determined to be Warner's King; also a dish of Bartlett's Glory a splendid Apple resembling Cellini in appearance, but much larger and firmer, six fruits weighing 7 lbs.; in season from November till January. It was raised by a market gardener, whose name it bears (award of merit).

Messrs. T. Rivers & Son sent a box of Golden Transparent Plum, a seedling of good size and delicious flavour, a freestone, full of honey-like juice. It was regarded as the richest yellow Plum ripening at this season of the year, and a first-class certificate was awarded.

Dr. P. H. Emerson sent a collection of Melons grown in the open ground in a sheltered garden near Broadstairs, Kent. Belgrade (Cantaloup) was small, but better in quality than many that have been before the Committee as grown under glass. A vote of thanks was accorded, also to Mr. W. H. Pitcher, Albury House, Surbiton, for firm fleshed Tomatoes, and to Mrs. Crawford, Galton, Reigate (Mr. W. Shawgrove, gardener), for ripe and good second crop fruits of Strawberries Black Prince and Vicomtesse Hericart de Thury. Mr. Shawgrove also sent seven Pears, grand fruits of Doyenné Boussoch, Beurré d'Anjou, Marie Louise, Beurré Diel, Maréchal de Cour, Doyenné du Comice, and

the ordeal at Chiswick as good croppers with handsome tubers of high quality when cooked.

A number of coloured illustrations of fruits by Mr. Oster, draughtsman to Messrs. J. & A. Cheal, were placed on the table. Some of the fruits were very well represented, and with practice Mr. Oster may develop into an excellent fruit artist.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); Messrs. Chas. T. Druery, H. B. May, R. Dean, G. Stevens, Frank Ross, J. D. Pawle, J. T. Bennett Pöe, Charles Noble, and the Rev. H. H. D'Ombrain.

Messrs. H. Cannell & Sons, Swanley, sent a collection of Cactus and decorative Dahlias comprising many new varieties of merit. The best amongst these were W. H. Myers, Duke of Clarence, Mrs. Douglas, Mrs. Hawkins, Maid of Kent, Princess Christian, Robert Maher, Claribel,

FIG. 35.—CLERODENDRON TRICHOTOMUM.

Fondante de Cuerne. A cultural commendation was unanimously awarded. Rev. J. H. Brown, Bedstone Rectory, Shropshire, had splendid fruits of Lane's Prince Albert Apples, not in the best of colour, but unusually large, well meriting the cultural commendation recorded. Mr. W. Bannister, The Gardens, Cote House, Westbury-on-Trym, sent twelve dishes of Pears, well grown, but not nearly so large as Mr. Shawgrove's (cultural commendation).

Messrs. T. Rivers & Son staged twenty-five dishes of fruit, including Apples, Pears, Plums, and Peaches, very fine specimens indeed, some being seedlings, and a silver Knightian medal was unanimously recommended; also to Messrs. John Laing & Sons, Forest Hill, who sent ninety dishes of Apples and Pears, the leading varieties being represented in a bright and good condition.

Messrs. Sutton & Sons sent splendid Onions of the variety A1, which received the highest number of marks of merit in the Chiswick trials, and a first-class certificate was at once awarded; also for dishes of their Windsor Castle and Triumph Potatoes, after passing with credit through

Kentish Invicta, and Cannell's Gem. An award of merit was adjudged for the last named variety, and a small silver Banksian medal was recommended for the whole. Messrs. W. Paul & Sons, Waltham Cross, sent a charming collection of Roses, including ten boxes of blooms, as well as various miscellaneous bunches. The flowers were delightfully fresh for the time of year, and it is not often that one sees such fine blooms in September. Particularly good were L'Ideal, La France, Clio, Pride of Waltham, Mrs. Jowitt, Grace Darling, Danmark, Star of Waltham, W. A. Richardson, White Lady, Ella Gordon, Eclair, Marie Van Houtte, and Duke of York, the last named being a new China Rose. A silver Flora medal was recommended. Messrs. T. H. Crasp and Co., Clyne Valley Nurseries, Swansea, sent some bunches of Asters and Celosias, the flowers being fresh and brightly coloured. A bronze Banksian medal was recommended. A box of new single Dahlias came from T. W. Girdlestone, Esq., Sunningdale, and for four of these awards of merit were adjudged. They were Golden Locks, Phyllis, Demon, and "M.C.C."; descriptions of these will be found elsewhere. The best of

the other varieties were Puck, Cinderella, Jack Sheppard, Yankee, and Splash. Mr. May, gardener to Captain Le Blanc, Northaw House, Potter's Bar, sent a dozen blooms of Dahlia Mrs. Le Blanc, a fine double

white, but no award was made.

Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, sent a box of hybrid Streptocarpus, the blooms, which were rich and varied in colour, having been cut from plants grown from seed sown in January of this year. The same firm had a box of Rhododendron javanicojasminiflorum hybrids, the most conspicuous of which were Monarch, Empress, Lord Wolesley, Aurora, Ophelia, Princess Royal, and Souvenir de J. S. Mangles. A vote of thanks was accorded for these charming flowers. A collection of Cannas came from the gardens of the Society at Chiswick, and the flowers of these were exceedingly bright. The best were Gloire d'Empel (Vilmorin), Alphonse Bouvier (Lemoine), Star of '91 (Allan), and Quasimodo (Vilmorin). An award of merit was adjudged for the latter, which is described elsewhere. Messrs. Stuart and Mein, Kelso, had a few bunches of Pentstemons, and Dr. P. H. Emerson, Claringfold, Broadstairs, sent some Tuberoses that had been grown in the open air.

Messrs. Dobbie & Co., Rothesay, contributed a collection of Violas, French Marigolds, and single Dahlias, and a silver Banksian medal was recommended. Amongst the Violas Sunrise, Rob Roy, Lucy Ashton, White Duchess, Lemon Queen, Dawn of Day, Duchess of Fife, and J. B. Riding were the most conspicuous. The Dahlias were attractive, especially Wilie Fyfe, Marion, Lucy Gray, and James Cook. The same firm sent a collection of new type of "Single Cactus" Dahlias, which attracted attention. These flowers are small with narrow petals, and are richly coloured. Roses and hardy flowers were well shown by Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, and a silver Flora medal was recommended. Among the Roses La France, E. Y. Teas, Eclair, Madame de Watteville, Duchess of Albany, and Général Jacqueminot were most noticeable, although the whole of the flowers were very fresh. An award of merit was adjudged for Noisette Rose Adeline Viviand Morel, which is described below. Messrs. Paul & Son also had two boxes of Phloxes, and an award of merit was given for Moliere, a very bright and distinct variety. The same firm also sent plants of Clematis Davidana, an herbaceous species that is not seen so frequently as it might be.

ORCHID COMMITTEE.—Present: Messrs. S. Courtauld (in the chair); Jas. O'Brien, J. Douglas, A. H. Smee, W. H. White, E. Hill, T. W. Bird,

H. Ballantyne, J. Jacques, and Dr. Masters.

Messrs. Sander & Co. had one of their familiar collections—choice, bright, and interesting. Habenaria carnea, for which they received a certificate a fortnight ago, was prominent in it; and there was also a pan of H. militaris, affording an opportunity of a comparison between the two forms as to size. H. carnea is about twice the size of the other. They also had Aërides Lawrenciæ, Warscewicziella Wailesianum, Miltonia Morelliana, and Cypripedium L'Unique (Lindleyana × Schlimi alba). The St. Albans firm also exhibited Bilbergia Saundersi and Cucuma Bakeriana in bloom (silver Flora medal). C. L. M. Ingram, Esq., Elstead House, Godalming (gardener, Mr. Bond), sent Cypripedium Adonis × (hirsutissimum × Curtisi) and Cattleya Alexandræ, Linden's Messrs. Hugh Low & Co. had a charming little group, in the magnificent Stanhopea Amesiana was very conspicuous. Its which the magnificent Stanhopea Amesiana was very conspicuous. ivory white glistening flowers, with their powerful and delicious Hyacinth-like perfume, were extremely beautiful. Cypripedium Brayanum, C. picturatum, and several other attractive forms were also in the collection, at the back of which was Lilium nepalense, the chocolate, green-tipped species, for which the firm received a certificate four years ago (silver Banksian medal). Messrs. Veitch & Sons contributed four Orchids, for three of which they received honours—an excellent record. They are described below. N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne (gardener, Mr. Murray), sent Cattleya-Lælia Clive. R. J. Measures, Esq., Cambridge Lodge, Camberwell (gardener, Mr. Chapman), sent Cypripedium Schomburgkian, C. Hebe, and several others (bronze Banksian medal). T. Statter, Esq., Stand Hall, Manchester, received a vote of thanks for an interesting collection of Cattleyas, including Leopoldi, Stand Hall var., Parthenia X, Victoria Regina, Statteriana, and others.

CERTIFICATES AND AWARDS OF MERIT.

Canna Quasimodo (Vilmorin).—This a grand Canna sent from the gardens of the R.H.S. at Chiswick. The flowers are large, bright scarlet

with a well-defined yellow margin (award of merit).

Cypripedium × Aphrodite (Veitch & Sons).—A very remarkable and beautiful hybrid, the result of a cross between C. Lawrenceanum and C. niveum, the former being the pollen parent. The dorsal sepal is almost orbicular, the petals short and extremely broad, being about an inch across, the lip short and blunt. The colouring throughout is white or ivory, suffused with rose and dotted with chocolate. The form exhibits a peculiar combination of the form and colour of the parents (first-class certificate).

Cypripedium Clotilde Moens (L'Horticulture Internationale).—A cross between C. Leeanum and C. Haynaldianum, distinct, but leaning to Leeanum in general expression. The dorsal sepal is white with a central bar of brownish red, the basal portion green. The twisted petals are green towards the base dotted with brown, the apical area light

purple (award of merit).

Cypripedium Leonæ (H. S. Leon, Esq.).—A cross between C. callosum (pollen parent) and C. insigne Chantini. It is noteworthy for its very long broad lip, the central portion of which is green dotted with

brown, the margins pure white. The petals are blunt and the lip

reddish brown (award of merit).

Cypripedium ano-superbiens (Sir Trevor Lawrence, Bart).-This, a cross between C. cenanthum, and C. superbiens, is a very bright and handsome form. The prevailing colour is a brownish red, this suffusing petals and lip. The former are broad and spreading, the latter somewhat pointed. The dorsal sepal is broad and beautiful, being heavily lined with chocolate dots and suffused with rose. Margin pure white (award of merit).

Dahlia Cannell's Gem (H. Cannell & Sons).—This is a small flower of the Cactus type, colour deep red. It is described as a "Pompon Cactus" (award of merit).

Dahlia Demon (T. W. Girdlestone) .- A handsome single Dahlia of

a very rich dark maroon, with a fine yellow disc (award of merit).

Dahlia Golden Locks (T. W. Girdlestone).—A very bright yellow single Dahlia, with flowers of perfect form and a good size (award of merit).

Dahlia M.C.C. (T. W. Girdlestone).—A distinct single Dahlia, and one that is likely to become popular. The flowers are large, and the colour a pretty mixture of gold and scarlet (award of merit).

Dahlia Phyllis (T. W. Girdlestone).—This is a pretty single variety with flowers of good size and form. The ground colour is a dull white

flaked and spotted with magenta crimson (award of merit).

Læliv-Cattleya Epieasta (J. Veitch & Sons).—Another bigeneric hybrid, and very bright. The parents are Cattleya Warscewiczi and Lælia pumila, the former being the pollen parent. It has the Lælia The flowers are large and brilliant, the sepals and petals being

rosy mauve, and the lip rich purplish carmine (award of merit).

Lælio-Cattleya Nysa (J. Veitch & Sons).—The same pollen parent was used for this—viz., Cattleya Warscewiczi, the female being Lælia crispa. The sepals and petals are soft pinkish lavender, the crisped lip purplish

carmine (award of merit).

Phlox Moliere (G. Paul & Son).—This is an attractive variety with

fine trusses of flowers, and a rich pink shade (award of merit.)

Rose Adeline Viviand Morel (G. Paul & Son).—This is a charming Noisette Rose with miniature rich yellow blooms, margin of petals tinted carmine (award of merit).

FRUITS.—A first-class certificate was awarded to Messrs. T. Rivers and Son for Golden Transparent Plum, awards of merit to Mr. W. H. Divers for Duchess of York Peach, also to Mr. Walter Weir for Cape Muscat Grape, and to Messrs. W. E. Browne & Son for Bartlett's Glory Apple, as described in our report of the Fruit Committee.

At the afternoon meeting Mr. J. Douglas read a paper on "Garden Phloxes and Pentstemons," which was listened to by rather a small though appreciative audience. There were not so many of these flowers exhibited at the meeting as might have been expected, and had there been more they would have done well to illustrate Mr. Douglas' remarks, which it need hardly be said were of a practical nature.

PINKS.

THIRTY years ago the Pink was in its zenith of glory, but since that period it has gradually declined, until at the present time one can seldom sec a good collection. It is very difficult to account for this change; but I am inclined to think it has been caused by the introduction of so many new plants. At the present day many people do duction of so many new plants. At the present day many people do not know anything at all about the show or laced Pinks. Most gardeners grow a few border varieties to yield blooms for cutting, and beyond that no special attention is paid to the plants. There is quite as much enjoyment to be derived from growing a collection of Pinks as from Carnations. There is a variety of colours and markings to obtain that will give the true florist plenty of labour to attain.

September is the proper season to commence their culture, and to be a successful Pink grower it is necessary to start with young plants. In bygone days the old florists used to carry out most elaborate directions when preparing the soil for their Pink beds; but I think the major part of those directions can be dispensed with, for, given a good fertile soil enriched with manure, there need be no difficulty as far as soil is concerned. At the same time poor ground requires the addition of some rich manure. The latter should be dug in some weeks previous to planting; but where this has not already been done it must be attended to before the plants are obtained. A cold wet soil requires a little more manipulation than a light one. Raised beds are the best in such places, and if 6 inches above the level of the ground it will be ample. Some people plant their Pinks in October, others even wait till the spring, which is a mistake. I like planting in September for two reasons; firstly, because the soil is generally in good condition then, and the plants can make new roots before severe frosts set in; and secondly, because most of the plants obtained from nurseries are ready during this month.

The plants may be 12 inches asunder each way. Place each plant a little deeper in the soil than it was before, and press the latter firmly. A light mulching of short manure will help the plants. Should the frosts cause any of the Pinks to rise out of the soil the grower must press them down again. I append the names of a few reliable varieties:—Boiard, Beauty of Bath, Beauty, Emerald, George White, Godfrey, James Thurston, Modesty, Irene, Ernest, Mrs. Campbell, Nellie, Pilot, Rosy Morn, and William Paul.—Jas. B. Riding.

NATIONAL CHRYSANTHEMUM SOCIETY.

I do not know who is responsible for the wording of the last paragraph re N.C.S. on page 224 of your last issue, but the impression it conveys is distinctly incorrect, as my offer was in response to a personal invitation by the Secretary. Kindly correct.—Chas. E. Pearson.

CHRYSANTHEMUM SHOW AT BORDEAUX.

THE 118th Exhibition of the Horticultural Society of the Gironde will be held on the 11th to the 18th November next. It will be devoted to Chrysanthemums and fruit, in the former of which are classes provided for plants in pots, seedlings not already in commerce, cut blooms, &c. Entries must be made by the 30th prox. The Secretary is Mr. G. Michel.

EARLY FLOWERING CHRYSANTHEMUMS.

Visitors to the recent Aquarium Show, and especially such as are interested in the Chrysanthemum, must have felt much disappointment at the meagre and far from satisfactory display that the early varieties made on that occasion. When we think that we have now hundreds of varieties to choose from, is it not strange that the exhibits were almost wholly confined to old-established sorts? As is usual at the September Exhibition, there were a few of the later sorts prematurely pushed into bloom to provide examples for the Show board; but this is a mere comment by the way.

In the best collections novelties were scarce, and the competitors seemed to prefer to rely upon varieties of old standing, the principal ones being the Desgranges family, Early Blush, Mrs. Jolivart, St. Mary, Golden Fleece, Fiberta, Mrs. J. R. Pitcher, Higham, Mr. Selby, Little Bob, Blushing Bride, Pynaert van Geert, and the like. The only flowers of modern introduction were Arthur Crépey (a small yellow Japanese), Gustave Grunerwold, Samuel Barlow, and Mr. E. Rowbottom, the last two receiving first-class certificates.

Perhaps the prize list was not sufficiently attractive to induce exhibitors to stage the best new varieties of recent introduction, but even if it had been I cannot help feeling that it is anything but encouraging to arrange Chrysanthemums beside the glowing brilliant colours of the Dahlia and Gladiolus. It makes them look tawdry, washed out, dingy flowers, and out of place with such gay companions close at hand. Seen beneath a dull November sky of the orthodox peasoup-coloured hue the Chrysanthemum is intensified in colour, or is apparently so, and possesses a charm which it never seems to have at any other season of the year. It is invaluable then; but when Dahlias, Asters, Gladioli, and other flowers can be had in galore, the question arises, Are Chrysanthemums wanted? I for one cannot help thinking— No! and the more strongly if the dull unattractive washed-out blooms we saw on the solitary table devoted to Chrysanthemums at the Aquarium last week represent all that is fairest to look upon in the way of early flowering Chrysanthemums.-P.

THE ROMANCE OF A GARDEN.

In an fold-fashioned garden, sufficiently modernised to prevent the existence of too much shade at the expense of light and air, we are at once, as I often feel myself, in the present and in the past. Surrounded, not too closely, by the venerable trees which our grandsires planted and our fathers greatly loved, each of these perhaps having through long associations with human experiences a history of its own, we breathe a tranquillity as if of other days. To watch from day to day, as the lover of Nature who possesses such a garden can always do, the development, so beautiful in its indefinable gradations, of plants and flowers; to witness the Enotheras or Evening Primroses unfolding their beauties when they are touched by the cool, freshening, energising twilight, while they kept folded by day under the influence of the sun; to behold in early dew-glittering hours of summer the fresh splendours of the Lily, the Carnation, and the Rose; this, more than all Romeo and Juliet romances, constitutes, to my consciousness, the purest poetry of life. It is not long since a great general, to whom I have often spoken, with his perfect approval, of the mental elevation which horticulture can confer, said that flowers were to him the very fragrance of an existence that had seen much of strife, and the conceptions to which I have given expression are the echo of his words.

At no period are our gardens more luxuriant in their aspect than At no period are our gardens more luxuriant in their aspect than during the tranquil season of autumn. Then the dark Roses, no longer scorched by the withering heat of summer, assume their exquisite velvety hue, not difficult to discern, but difficult to define. Then, in my own garden at least, every aged tree is covered to a height of 15 feet with the glorious blossoms of the great Tropæolum, the Scarlet Runner, and the fragrant Sweet Pea, the last mentioned blooming—in consequence of the prevention of seed pods—from the end of June in consequence of the prevention of seed pods—from the end of June till the beginning of December, when the frost comes suddenly and cuts it down. Here also, at this season, border Carnations, the yellow Germania, crimson Clove, the pink-hued Raby Castle, and the fragrant white Gloire de Nancy, combine with the autumnal Roscs by which they are surrounded to produce a splendidly artistic effect

The Carnation has been described by the Dean of Rochester as "First Lady-in-Waiting to the Rose;" but during the last month, notwithstanding all her efforts to keep pace with her, the queen of flowers has been completely in the shade. Twice during the seasons of summer and autumn does the Rose assume the royal sway; during her period of repose the Carnation reigns supreme. But both have powerful rivals in Lilium auratum and Lilium speciosum, which contribute powerfully to the fragrance and beauty of the garden in their season.— DAVID R. WILLIAMSON.

LITTONIA MODESTA.

ALTHOUGH this Littonia is said to have first flowered at Kcw about forty years ago it does not appear to be generally grown in gardens,

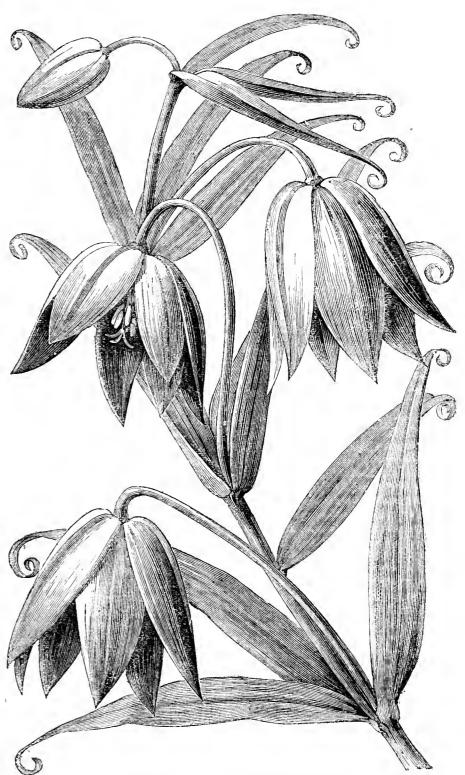

FIG. 36.—LITTONIA MODESTA.

inasmuch as a young gardener writes to say that he has "never seen a specimen, and should like an illustration of it to appear in the Journal." We comply with the request, and add a few particulars concerning the

Although nearly related to the well-known Gloriosa superba, this little plant is quite distinct enough to take generic rank, and though of an unassuming character as its name indicates, it is of graceful habit, and the freely produced flowers are brightly blurred. Littonia modesta is a native of Natal, where it was found by Mr. John Sanderson during a journey in 1851 from Port Natal to Maritzburg. In habit it is much like the Gloriosa, having tapering leaves terminating in a tendril-like point, which aids it in climbing stems or twigs. The flowers are borne in the axils of the leaves, are drooping, and bright orange coloured. The tubers are of peculiar shape, brownish, and have been compared to a Spanish Chestnut, and the manner of growth is very curious. It has been grown in a stove and in cooler quarters, but an intermediate temperature and sandy soil seem to suit it best.

"ART OUT OF DOORS."

This is the title of a work by Mrs. Schuyler van Rensslaer, and produced by T. Fisher Unwin in a form which reflects the highest credit upon the skill of the publishers. Those who have any acquaintance with New York will at once perceive that the authoress is, by name at least, connected with families of genealogies sufficiently traceable to have become historical in the oldest of the United States.

The book is written in the spirit of an enthusiast, and in a style which is flowing and agreeable, though here and there are traces of journalese that might have been corrected with advantage before the issue of the collected articles. Why, we ask, has the good old-fashioned word "mark" gone completely out of use now-a-days in favour of the words "emphasize," and "accentuate?" Nobody "marks" or "intensifies" an idea or feature in these advanced days, he always "emphasizes" or "accentuates" it. There is everything to be said in favour of enriching a language with equivalents, but in the effort to make the new comers take root writers use them with a persistency that becomes monotonous, and without always a delicate sense of what is appropriate. It may be becoming in Mr. Gladstone when making some of his oratorical flights to vary his diction with such high sounding terminology as those words above mentioned, but in more simple styles such as this one treating of gardening the older ones would have been as good or better. So, too, with many writers on gardening; no opportunity is lost of dragging in the word "environment" by way of making a small subject bigger, instead of being content with the words "surroundings," "situation," position," or the simple word "place."

Mrs. Schuyler van Rensslaer, as we said before, writes very pleasantly

Mrs. Schuyler van Rensslaer, as we said before, writes very pleasantly and voluminously upon the subject of landscape gardening, which is clearly a favourite one with her. She lays down, too, certain principles, but they are usually of a very broad and indefinite sort, and so variable with the conditions of each case as to be scarcely of any service to a novice. Indeed, without diagrams it is difficult to see how such an intricate subject could be made intelligible except to an expert. The first condition is that the materials upon which the landscape artist has to work are known. In the absence of this, the most that can be done is to indicate the most glaring faults to be avoided. As Mrs. Van Rensslaer says, the art is a difficult one, being the offspring of these latter and more highly cultured days, and therefore still in its infancy. There must be much more æsthetic cultivation of the people before the landscape-gardening enormities of the present become offensive and unpalatable. In her condemnation of the use of masses of highly coloured plants everywhere, she is amply justified, as it is but rarely that these are sufficiently subdued. Her quotation of a French artist's definition of ordinary peoples' idea of gardening is quite in keeping with the interest she shows in promoting the art. This is "the clearing up of spontaneous vegetation followed by the accumulation of strange and dissimilar objects."

In the chapter entitled "A Word for Books," Mrs. Van Rensslaer makes out a very good case in opposition to those who attack the scientific names of plants as being unwieldly and unpoetical. In some cases the vernacular names may be superior to the scientific, but in most cases they are no better or even inferior, and of course are unintelligible beyond their own frontiers. It is difficult to see why "goose foot," or "fat hen" is more euphonious than Chenopodium, or "Flower of the West Wind" than Zephyranthes. Indeed the scientific names being Latinised are better suited for the sweetness and dignity of verse than the local ones. Want of familiarity, that is want of knowledge, forms in nearly every case the ground of objection to them.

"Art Out of Doors" is written for Americans and for the climatic conditions prevailing in the United States, and therefore cannot be accepted by English people except in a qualified way. It is, however, very agreeable and instructive reading for those who are interested in the domestic life of our kinsfolk across the water, as we can note therein how the habits of our ancestors have become modified by the force of altered circumstances upon a new continent.

HORTICULTURAL SHOWS.

DERBY.—SEPTEMBER 6TH AND 7TH.

This was the annual meeting of the Derbyshire Agricultural and Horticultural Society. The entire Show was an improvement on former meetings, and the horticultural department was 50 per cent. better than it was last year. The display was certainly excellent, admirably arranged in three tents, so constructed that while each tent contained mainly a separate section, all three were connected, and the entire exhibition could be inspected as a whole under one roof, or rather, connected series of roofs. This is a first-rate plan at a combined meeting of horticulture and agriculture especially, but it is also worthy of adoption for any horticultural exhibition.

of adoption for any horticultural exhibition.

The exhibits in the section for gentlemen's gardeners were arranged in a commodious circular tent, the centre being devoted to plant groups, tastefully enclosing a bold mass of Palms. The effect as a whole was

exceptionally fine, the Palms forming a capital background to every group, while giving due importance and height to the centre. Admirably was the entire space filled in response to a generous offer by the Committee of twice the amount hitherto given. Class 1, open to all England, brought five groups into competition, the whole of them displaying much skill both in culture and grouping. The first prize was well won by Mr. J. Ward, gardener to G. H. Oakes, Esq., Riddings House, with a charming group, in which lightness, elegance, and tasteful blending of colour was exceedingly well done. There was very little blossom, the rich foliage of Crotons, with the brighter hue of Grasses, and the greenery of Palms and Ferns, combined in perfect taste to form an artistic arrangement entirely worthy of the £20 awarded it. Mr. Cypher of Cheltenham came second, a really good second, the veteran exhibitor having no reason to be ashamed of being beaten by so able an adversary as Mr. Ward. Mr. Webb, Kelham Hall, Newark, was third with also a fine group, having Palms and green Dracænas springing out of a well blended undergrowth of Ferns, Grasses, Caladiums, and small highly coloured Crotons, and most remarkable of all was the fourth prize group from the fact of the winner being Mr. Shakespere of Tibshelf, a working collier.

For twelve stove or greenhouse plants Mr. Finch of Coventry was first with large, well-finished specimens, Erica Marnockiana, Crotons Prince of Wales and Queen Victoria, Erica Atoniana Turnbulli and Ixora being the most noteworthy as noble specimens in perfect condition. Mr. Vere, gardener to — Gisbourne, Esq., Allestree Hall, was second. He also had a first prize for grand specimen Lycopodiums. For a collection of Ferns Mr. Ward was first with some magnificent plants, the perfection of high culture and finish; Mr. Vere being second, a Pteris argyrea in his group being very striking. There were only two entries for baskets of plants, both being so good that the merit was almost equal. Mr. Ward was first and Mr. Vere second. Roses were not well represented, only six stands being shown. For twelve, Mr. Robinson was first, Mr. Carrington second, and Mr. Henson third. Most of the blooms were inferior, and none call for special mention. In the class for six blooms the same three exhibitors were in competition, the first prize going to Mr. Henson, the second to Mr. Robinson, third Mr. Carrington. Dahlias were also in moderate numbers, calling for no special mention. Mr. Carrington was first with a grand dozen of doubles, second for six, and first with a good stand of Cactus Dahlias. Mr. Henson won a second, third, and fourth prize in this class, and Mr. Robinson two thirds. Mr. Carrington was well to the front for twelve Zonal Pelargoniums, Mr. Henson taking first prize for double Pelargoniums. Verbenas and Gladioli were moderately shown, and with Asters Mr. Robinson's first prize stand had some perfect blooms. For hand bouquets Mr. Robinson took first honours, Mr. Henson second, Mr. Carrington third, and Mr. Bolas fourth. Mr. Bolas also second, Mr. Carrington third, and Mr. Bolas fourth. had first for a tastefully dressed epergne.

In the fruit classes Grapes made a grand display, most of the bunches being exceptionally fine and well finished. For two bunches of Black Hamburgh Mr. Campbell had perfect samples, large in bunch and berry, of splendid colour and finish. Mr. Woodward was second with fine well shouldered bunches, Mr. M'Vinish a close third, and Mr. Evans fourth. Mr. M'Vinish had two grand bunches of Muscats, and was an easy first, Messrs. Innes & Co. of Littleover being a good second, Mr. Billings third with small highly coloured fruit, and Mr. Campbell fourth. For black Grapes other than Hamburghs Mr. Campbell's two bunches of Gros Maroc were magnificent, the berries being enormous. The champion prize for the finest two bunches of Grapes in the Show was also awarded to these splendid examples of skilful culture. Mr. M'Vinish was second with his excellent Alicante, and Messrs. Innes & Co. were third with enormous bunches of Gros Guillaume. For white Grapes other than Muscats Mr. Billings was first and Mr. Read second. In the competition for the Mayor of Derby's (W. H. Marsden, Esq.) special prizes Mr. M'Vinish was first with splendid bunches of Black Hamburgh, Muscat of Alexandria, and Alicante, Mr. Campbell being second, and Messrs. Innes third.

Mr. Ward's first prize Tomatoes were twelve perfect specimens, Mr. Webb was second, and Mr. M'Vinish third. They are mentioned here as they were placed among the fruits. Pears were a small class. There was a fair display of Melons, Mr. Billings taking first honours with a fine example of Reid's Scarlet-flesh, Mr. Evans being first with a greenfleshed variety. Mr. Ward's fine plate of Peaches easily won the first prize; Mr. Webb was second, and Mr. Woodward third. Mr. Campbell had a first prize for the only plate of Nectarines shown. Among other fruit Mr. Read's Pond's Seedling Plums are worthy of special mention; they were shown in his first prize collection of fruit.

Collections of vegetables made a good display, a common fault being in the usual direction of excessive size. Mr. Ward was first, Mr. Read second, and Mr. M'Vinish third. Collections of eight dishes of Potatoes were a remarkable feature, the whole of the six entries being splendid examples of skilful culture. The names of the prizewinners were not appended, but the first prize went to eight grand plates of Reading Ruby, Wormleighton Seedling, Prizetaker, Sutton's Seedling, Reading Giant, Reading Ruby, Satisfaction, and Windsor Castle.

Section 2, for persons not employing a gardener, contained some produce of much excellence. Taking them as we went round, the most noteworthy were hand bouquets decidedly superior to those in the first or gardeners' section. Roses were more numerous in this class. Dahlias were very fine, the first prize flowers of Mr. J. Wood being grand specimens. There was also a creditable display of Asters, Gladiolus, Pansies, Marigolds, and baskets of cut flowers. Grapes were well shown,

so, too, were Apples, Cucumbers, and Tomatoes. The vegetables shown in this section were highly creditable, most of the classes being well filled, many of the vegetables being good in quality, but the Cauliflowers were too large. Collections of herbs were excellent.

In the cottagers' section there was an imposing display of vegetables, upwards of fifty plates of Potatoes being among the more conspicuous features. Cabbages, Carrots, Parsnips, Turnips, Vegetable Marrows, and Onions all being superior examples of high cultivation, and the collections of vegetables, of which there were nine, were also of remarkable excellence.

BIRKENHEAD AND WIRRAL.—SEPTEMBER 7TH AND 8TH.

THIS Exhibition, in connection with the Agricultural Show, was held on the above dates at the Bidston Show Ground, and was a decided advance on previous years, both as regards the entries and the general excellence of the exhibits. Fine weather prevailed on the first day, and

in consequence the attendance was very large.

For five foliage and five flowering plants, Mr. A. Brown, gardener to Geo. Webster, Esq., was first with a very good collection, the best flowering plant being Ixora coccinea, and foliage, Croton Rothschildianum. Macgregor Laird, Esq., was a good second. For a group of plants arranged for effect, Mr. J. Bounds, gardener to A. L. Jones, Esq., Aigburth, took first honours, Mr. E. Bradshaw second, and Macgregor Laird, Esq., third. They were much after the style of the smaller groups which have been from time to time commented upon in the Journal. For three stove or greenhouse plants in bloom, Mr. A. Brown was first, having a fine Ixora coccinea. For a similar number of foliage plants the same exhibitor was again successful, also for one greenhouse plant in bloom, one stove plant in bloom with a very fine Dipladenia, one foliage plant, three Ferns and one Fern, three Tuberous Begonias, three Pelargoniums, and one Fuchsia, a most creditable performance, those competing against him having plants of the highest The second prizes were taken by Macgregor Laird, Esq., for the three foliage plants, greenhouse plant in bloom, three stove and greenhouse plants in bloom, and three Tuberous Begonias. Mr. J. Bounds was second for three Ferns, the prize for one Palm going to Mr. J. W. Totty, gardener to W. Laird, Esq. Mr. A. J. Stanley, gardener to J. R. Callander, Esq., took the prize for three Coleuses, and Mr. J. Bounds for table plants. Bounds for table plants.

Cut flowers, particularly Dahlias and Asters, were splendidly shown, and the competition was keen. For the best bouquet the first prize was won by Mr. S. Johnson, the second going to Mr. J. Williams, gardener to C. J. Procter, Esq., the latter winning in classes for sprays for ladies and buttonhole bouquets for gentlemen. Mr. R. Brownbill, gardener to J. C. Sinclair, Esq., was successful with six Roses; Mr. C. Terry, gardener to C. H. Skelsey, Esq., had the best three blooms. For twelve Cactus Dahlias Mr. A. J. Stanley was an easy winner, his blooms being fresh, solid, and very fine in colour. Mr. J. H. Bennett was second. The same exhibitor was also first for six Cactus Dahlias. The prizes for twelve Dahlias and six other than Cactus were taken by Mr. J. Lee twelve Dahlias and six other than Cactus were taken by Mr. J. Lee, the second going to Mr. J. Clarke. The prizes for six Gladioli, six Asters, and six outdoor cut flowers went also to Mr. Lee. For twelve Asters J. Howell, Esq. (gardener, F. Davies), was first; and for six Asters and twelve varieties outdoor cut flowers Macgregor Laird, Esq., was successful. The prizes for Hollyhocks and Everlasting Flowers went to Messrs. T. Brocklebank and Williams. The awards for twelve, six, and three varieties of cut flowers grown indoors fell in each instance to Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, with a choice collection, the second prizes going to Messrs. Brown and

Bounds.

For six dishes of fruit Mr. M. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, was first, the collection being very fine in every respect. The second prize was won by Mr. G. McCreadie, gardener to J. W. Haigh, Esq. For a collection of hardy fruits the first prize was secured by Mr. C. Worker, gardener to Mrs. Blomfield. Second Mr. Hannagan. Mr. R. Brownbill won with two bunches Black Hamburgh, small in berry, but well coloured. Mr. Ferguson, gardener to Mrs. Paterson, Rock Ferry, was second. For two bunches of Grapes, any other black. Mr. J. Bichards, gardener to Mrs. Friend, was first any other black, Mr. J. Richards, gardener to Mrs. Friend, was first with fine Madresfield Court, Mr. R. W. Hudson being second with same variety. The first prize for two bunches of Muscats was well won by Mr. J. Barker gardener to Alderman Raynes, Rock Ferry, with well finished samples, whilst Mr. McCreadie won for any other white with Buckland Sweetwater. With six Nectarines Mr. Hannagan was the only exhibitor. In the class for Peaches Mr. R. Pinnington won with a grand dish of Gladstone, large in size and fine colour. The prizes for scarlet-flesh Melons went to Messrs. Ferguson and Pinnington, and for green-flesh to Messrs. Hannagan and Pinnington. Apples were especially fine, the prizes for six dessert going to Mr. John Clarke, six Lord Suffields to Mr. W. B. Burnham; whilst for six of any other culinary variety the first and second exhibits of Peasgood's Nonesuch, staged by Messrs. Williams and Hannagan, were much admired. Messrs. Ferguson and Lee won with dessert Pears, and Mr. T. Watkinson with Plums.

The collections of vegetables were all of the highest merit and made a most extensive display. For eight distinct kinds Mr. S. Salisbury, gardener to C. H. Carson, Esq., secured the leading prize, the Cauli-flowers and Carrots being particularly fine. The second prize went to Mr. J. Williams for smaller produce. In the open class for eight distinct kinds, Mr. McCreadie was successful also with a fine exhibit. Tomatoes were well shown, there being eighteen exhibits entered in class for twelve fruits. Mr. McMaster, gardener to Sir Ughtred K. Shuttleworth, Ganthorpe Hall, Burnley, was successful with fine, fresh and even fruits of Perfection. For six, T. Brocklebank, Esq., was placed first. Potatoes made a great display, being of excellent quality throughout. For twelve white rounds and same number of kidneys the prizes went to Mr. James Ismay, and for corresponding classes for coloured Potatoes to Mr. Thomas Woolrich. Onions, Leeks, and Shallots were in abundance, the prizes going to Messrs. McCreadie, Richards, J. Piggott, Mrs. G. Cooke, and Mr. Woolrich in the order named. Beans, Peas, Celery, Cucumbers, Cauliflowers, Vegetable Marrows, Lettuce, Cabbages, Beetroots, Parsnips, Turnips and Carrots were well shown.

Messrs. Webb & Sons of Stourbridge were awarded a gold medal for

an extensive assortment of agricultural seeds, vegetable seeds and dried specimens of various Grasses, which made an imposing stand. Another representative stand was arranged by Mr. H. Middlehurst, Manchester Street, Liverpool, and a silver medal awarded. Messrs. Dickson (Limited), Chester, also took honours with a tent filled with choice collections of stove and greenhouse plants, Dahlias and herbaceous cut flowers, which were much appreciated. Other exhibitors were McHattie & Co., Chester, with a display of seeds and natural Grasses.—

R. P. R.

EARL'S COURT.—SEPTEMBER 13TH.

A VBRY attractive display was got together on this occasion, the drawback being that it was too large, so much tabling being in demand that the marquee was too full to afford much room for promenading, and even under this condition of affairs overflow space had to be found in another part of the building. Dahlias were a great feature, the groups of them being extremely beautiful. Asters, Helianthuses, and hardy flowers generally were also in good force, and the fruit exhibits

were an attraction in themselves.

There were three stands in the principal Dablia class—that for sixty blooms, Show and Fancy, and Mr. C. Turner followed up his Palace victory by scoring with an excellent stand, his flowers being in splendid condition. They were very smooth, even, fresh, and well coloured, the best being William Keith, Mrs. Saunders, John Hickling, George Rawlings, Grand Sultan, Kathleen, Richard Dean, and Clara. Messrs. Keynes, Williams & Co. had distinctly smaller flowers, and they were perhaps hardly so smooth as those of Mr. Turner, but in other respects they were excellent, colour and cleanliness being irreproachable. They were excertent, colour and creaminess being interpolations. They were placed second, and the third prize was given to Mr. Mortimer, a point being strained in his favour, as he had James O'Brien (self) and Duchess of Albany (self), which are duplicates, in his stand. Messrs. Saltmarsh & Son had a beautiful stand of twenty-four, the flowers being Saltmarsh & Son had a beautiful stand of twenty-four, the flowers being Saltmarsh. delightfully fresh, clean, and fine. Perfection, Harry Keith, Peacock, and Colonist were extra good. Mr. Arthur Rawlings was second, and Mr. G. Humphries third.

In the amateurs' class for twenty-four, Show and Fancy, Mr. J. T. West, gardener to W. Keith, Esq., Cornwalls, Brentwood, won with an admirable box, the flowers being very smooth and even. Mrs. Gladstone, Geo. Rawlings, Harry Keith, Lustrous, and Prince Bismarck were a few of the best. Mr. Hobbs, St. Mark's Road, Euston, was second, and Mr. Vagg, gardener to W. Theobald, Esq., M.P., Bedfords, Romford, third. With twelve, J. G. Fowler, Esq., Glebelands, South Woodford won, and he had an admirable box, all the flowers being shapely, fresh clean, and bright. Mrs. Gladstone and Maud Fellowes were perhaps the two best. Mr. W. Hopkins, New Passage, Bristol, was second with

smaller blooms, and Mr. Cooper, Chippenham, third.

Messrs. Keynes, Williams & Co. had the best of four stands of eighteen Cactus or Decorative, nearly all their varieties being of the true Cactus type. Delicata, Lady Penzance, Apollo, Sir Roger, Bertha Mawley, and Gloriosa were particularly noticeable. Messrs. Cheal and Sons followed, their best being Robt. Cannell, Ernest Cannell, Kaiserin, Sir Roger, and Bertha Mawley. Messrs. Burrell & Co. were third. The best amateur's box of Cactus was that from Mr. Brown, gardener to M. W. Morris, Esq., Oak Lodge, Horley, who had very fine clusters of Kynerith, Professor Baldwin, and Delicata amongst others. Mr. J. Stredwick, Silver Hill, St. Leonards, was second, and Mr. West third. The latter was first with Pompons, Messrs. Cooper and Stredwick following. All were very good stands, Mr. West's flowers being charming in the extreme. There were four collections of twenty-four charming in the extreme. Pompon varieties in bunches of ten (nurserymen), the best being that of Mr. C. Turner, whose flowers were in perfect condition. Eric, Rosalie, Mars, Eurydice, Rowena, and A. West were exceptionally good. Messrs. Cheal & Sons were a close second with delightful clusters, and Messrs. Keynes, Williams & Co. were third. Only one stand of twelve singles turned up out of seven entries, and that came from Mr. Girdlestone. It was a beautiful box, and well merited the first prize.

Prizes were offered for a collection of Dahlias grouped for effect,

and they made a magnificent display, all being arranged with taste and informality. Messrs. Cheal & Sons were placed first and the award was undoubtedly correct, although Messrs. Keynes, Williams & Co. made a good fight. The Crawley firm had employed singles and Pompons with admirable taste. Messrs. Paul & Son, Cheshunt, were third.

Mr. Wythes appeared to have made a special effort in the class for a

collection of stove and greenhouse flowers, and won with consummate ease. He had splendid clusters of Nerine Fothergilli major, a new and beautiful blush-coloured Dipladenia named Lady Louisa Edgerton, Dendrobium Phalænopsis Schröderiana, Aërides Lawrenciæ, Hymenocallis macrostephana, and several Bouvardias. It was a splendid box. Mr. J. Prewitt was second; and Mr. Gibson, gardener to T. F. Burnaby Atkins, Esq., third. Messrs. Paul & Son won with a collection of Michaelmas Daisics; Messrs. Burrell & Co. being second, and Mr. Such third. Messrs, Burrell were first with Sunflowers, being followed by Messrs. Paul and Such. Three out of four stands of hardy annuals were disqualified, and to the other, that of Mr. Salmon, the third prize was awarded. Messrs. Saltmarsh & Son won with Asters; Mr. Walker being second, and Mr. Humphries third. Mr. Such won with early Chrysanthemums, having large and beautiful bunches; and Mr. Vince,

Highgate Cemetery, was second.

There was some excellent fruit. Mr. Woodward, gardener to R. Leigh, Esq., Barham Court, Maidstone, won with three dishes of Peaches, having splendid fruit. Mr. Carr, gardener to Mrs. Clarke, Croydon Lodge, second; and Mr. Potter, gardener to Sir Mark Collet, Bart., Kemsing, third. Mr. Sanders, The Gardens, Paulton, Romsey, Hants, had the best single dish, a grand one of Sea Eagle; Messrs. Woodward and Wallis (gardener to Ralph Sneyd, Esq.), being second and third with the same variety. There was only one dish of second and third with the same variety. There was only one dish of Nectarines, this coming from Mr. R. Edwards, Sevenoaks, and the second prize was awarded. Mr. Woodward won with three dishes of dessert Apples, having Cox's Orange fairly good, and Ribston and Washington excellent. Mr. P. Cavanagh, Roehampton, was second, and Mr. Potter third. There were seven other competitors. Culinary varieties were still better. Mr. Woodward won again, having magnificent fruit of Stone's Peasgood's and Warner's King. Mr. Nicholson. cent fruit of Stone's, Peasgood's, and Warner's King. Mr. Nicholson, gardener to J. W. Melles, Esq., Chingford, was second; and Mr. Cavanagh third. Mr. Woodward had some splendid Pears, and won easily from Messrs. Potter and West, gardener to H. J. Wigram, Esq., Salisbury. The Maidstone grower had splendid fruit of Pitmaston, Marguerite, Mairillat, and Souvenir du Congrès. Mr. MeIndoe, gardener to Sir J. Pease, Bart., M.P., Hutton Hall, Guisboro', won with a collection of cooking and market Plums; and Mr. Potter was second. Mr. McIndoe scored two other victories with Plums, winning with three dishes of both dessert and cooking varieties. excellent fruit in both. The minor awards went to Mr. T. A. Hester,

gardener to W. G. Dawson, Esq., Plumstead, and Woodward.

The non-competing exhibits were extensive and beautiful. Mr.

J. Walker of Thame had a splendid collection of Dahlias and Asters, for which he received a silver-gilt medal; but many would have liked to see him tackling Mr. Turner in the sixty class. Mr. Mortimer also had a large collection of Dahlias, and received, as he deserved, a silver medal. Messrs. J. Laing & Sons put up one of their best efforts in the way of Begonia groups, the material and the arrangement being of equal excellence (gold medal). Mr. Turner supplemented his victories in competition with a fine display of Show and Fancy Dahlias (silver medal). Miss Cole received a silver medal for table decorations. Mr. T. S. Ware put together a very fine collection of Dahlias, Cactus, single and Pompon, arranged in a pleasantly informal manner, and very beautiful (gold medal). Mr. J. R. Tranter showed Asters and Dahlias (bronze medal). Messrs. J. Veitch & Sons had a box of their beautiful hybrid Streptocarpus, and a first-class certificate was awarded for the excellence of the strains. Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, The Palace, Wells, received a silver medal for a very fine dish of Peasgood's Nonesuch Apple grown on a cold damp wall. Mr. Maher, gardener to A. Waterhouse, Esq, received a bronze medal

Messrs. Cannell & Sons were represented by a brilliant collection of dwarf Cannas (silver medal). Messrs. Saltmarsh & Son were awarded a bronze medal for Asters and Dahlias. Mr. Walter Salmon, the "postman florist," had a beautiful collection of Dahlias and other flowers (silver medal). Mr. T. A. Hester had a very extensive display, comprising ornamental Gourds and forty-five dishes of Apples (silver-gilt medal). Mr. Wilkins, Inwood House Gardens, Henstridge, had some magnificent Onions—Somerset Hero, Prizewinner, Ailsa Craig, and Lord Keeper being very noteworthy (silver medal). Messrs. Paul & Son, Cheshunt, were awarded a silver medal for a large and fine collection of Apples and Pears. Messrs. S. Spooner & Son had an excellent display of Apples and Pears (silver-gilt medal). Mr. Such received a silver, and Mr. Humphries a silver-gilt medal for Dahlias, both representative collections. Mr. Poupart, of Twickenham, sent Apples, Pears, and Plums, which were very fine (silver-gilt medal).

HARDY FRUIT GARDEN.

Strawberries .- New plantations will require the soil loosening between the plants with the Dutch hoe, not only to destroy crops of seedling weeds that spring up rankly after showers, but also to encourage the growth of the plants as much as possible before winter.

Late Planting .- Plants for furnishing a fair amount of fruit next season may still be planted, but such should have been specially prepared for the purpose, either by being rooted and kept moist in pots or turves, or well-rooted isolated plants obtained from between the rows. Such plants, carefully and quickly inserted, will be little if at all inferior to those planted earlier. If sufficient plants are not by these means secured the best of the smaller-rooted runners may be lifted and replanted 6 inches or so asunder in nursery beds, where they may remain through the winter, planting permanently in rows in the spring. plants placed out late in open quarters or rows often succumb to adverse weather, because they are not established enough to bear in winter and spring sudden climatic changes.

Cleaning Strawberry Quarters.—Except where fresh plantations have not already been formed, and all the plants required secured, it is not advisable to delay removing the runners and cleaning between the rows to this late period. Even when many plants are wanted much may be done to relieve the stools by detaching the runners immediately the young plants have become rooted. Remove all weak and crowded plants, especially clearing away those from near the old stools, so that the latter may receive a fair share of light and air to mature the Weeds often grow too freely in Strawberry beds, but they should be cleared away.

Mulching.—To replenish the impoverished state of the ground between the oldest stools somewhat, and assist the plumping up of bold crowns during the autumn, it is desirable to afford a light mulching, about an inch thick, of partially decayed stable manure. A similar

application may also be afforded new early-planted beds.

Outdoor Figs.—Gather ripe Figs as they become ready, which may be known by the fruits drooping, the skins being slightly cracked and juice exuding therefrom. In this condition the fruits are delicious. Stop all shoots which are extending too far or for which there is not sufficient space to lay them in without being shaded by others. Thin crowded shoots, removing weak spray and strong, gross, soft growths. Retain all short-jointed shoots unstopped, as these, well ripened by exposure now to sun and air, will prove to be the most fruitful parts in the succeeding seasons.

Outdoor Vines .- Attend well to the roots of Vines now ripening fruit on walls, so that they do not suffer from lack of moisture, occasionally supplying liquid manure or soapsuds as additional support. White Grapes will need plenty of light to assist them to ripen, black varieties colouring best under the slight shade of foliage. Expose the current year's wood to light and air in order to ripen it and plump up the buds. Reduce lateral growths as becomes necessary.

Stopping Secondary Growth on Wall Trees. - Summer pruning duly carried out on Plum, Apple, Pear, Cherry, and Apricot trees will have resulted in many cases in secondary growth being made, this starting from the upper buds of shoots that have been shortened. If the summer pruning was dealt within an intelligent manner no harm results from new shoots starting and elongating from the upper buds at this season, provided they are stopped to one leaf when six full sized ones have been made. If not checked such shoots go on growing, appropriating an undue share of sap which is intended by the stopping to be concentrated on the lower buds, those developed in the axils of the leaves left at the first or summer pruning.

Preparation of Ground for Planting Fruit Trees.—A friable condition of the soil at the time of planting will conduce much to the readiness with which trees can be planted. It is important, therefore, to commence the work of preparing the ground forthwith. In most cases either deep digging or trenching will be needed so as to loosen the soil to a depth of 2 feet, manure consisting of decayed stable manure being added if poor; but none if the ground is fairly rich and fertile. Early preparation permits of the surface soil becoming ameliorated and the bulk consolidated; besides, where extensive planting may be contemplated there will be considerable advantage in having the sites in readiness, so that planting may be expeditiously performed when the most favourable opportunities arise as the trees are losing their leaves.

FRUIT FORCING.

Vines.—Early Forced and Potted Vines.—There must not be any further delay in the pruning of Vines intended to ripen their fruit by the end of April or beginning of May, and in cleansing the house and Vines, so as to have all in proper working order. Vines in pots should have the laterals cut off close to the canes, but do not injure the main Shorten the canes to about 8 feet, or lower according to the disposal of the plump eyes or the length required, and dress the cuts with Thomson's styptic or patent knotting to prevent bleeding.

Young Vines.—Every encouragement must be given for ripening the wood and plumping the buds. This can only be properly effected when the foliage is kept elean and healthy to the last. Laterals produced after this time tend to retard the ripening of the wood, therefore remove or keep them closely pinched. Where laterals have been allowed to extend considerably they should be shortened by degrees, so as to remove them altogether without starting the principal buds or those on the cane. Maintain a rather warm well ventilated atmosphere until the canes are ripe, which may be accelerated by having a temperature of 85° to 90° from sun heat, opening the ventilators fully at night. Any supernumeraries intended to produce fruit next season should have the laterals cut away to the principal buds, not, however, all at once, but gradually, leaving sufficient lateral length as an outlet for any excess of sap.

Late Houses of Black Hamburghs. - The Grapes are now well advanced in colouring. The ripening must be thorough or the Grapes will not keep well, and to effect this a gentle warmth in the pipes is necessary, to admit a free circulation of air, and to maintain the night temperature at 60° to 65°. A little artificial heat during the day will also be of benefit in allowing of free ventilation and making the

most of sun heat. Hambur, hs colcu, and finish best beneath a gool spread of foliage, as also does Madresfield Court, but it is as well not to encourage lateral growth now; at the same time it must be borne in mind that the tendency to shanking is accelerated by large reductions of foliage, and equally so by sudden fluctuations of temperature. air should be admitted through the top and bottom ventilators until the Grapes are ripe. If there is any deficiency of moisture in the borders it will be better to give a supply now than at a later period, covering with some dry material, so as to prevent damp rising. A free circulation of air, however, is the best safeguard against the Grapes damping, for the fungal germs that produce spotting and decay require a still and damp air for seating and germination.

Outside borders will in most instances be sufficiently moist—if not they must be watered, and unless the weather set in unusually wet they need not be covered at present; but glazed lights, shutters, or tarpaulin should be in readiness for placing over them, so as to throw off continued heavy rains. Where the borders are well raised above the surrounding level, have a good slope, and are composed of porous material over thorough drainage it is not necessary to cover them; but the Grapes sometimes decay wholesale when the borders are very rich

and close and soddened by heavy rains.

Late Muscat Houses.-The Grapes are close upon finishing, but they are not by any means matured, as they will continue to acquire colour and quality as long as the leaves are green. There must not be any attempt at removing the leaves, but allow them to remain until they part naturally at the base of the footstalks from the shoots. The bearing shoots should be given plenty of space, so that throughout their growth every leaf will have full exposure to light. Where the Grapes are not now ripe the night temperature ought to be kept at 65° to 70°, and the heat should be turned on in good time in the morning, so as to allow of an increase of ventilation, and the temperature be raised to 70° to 75°, and kept at 80° to 85° from the sun. The heat should be kept up by reducing the ventilation, with the declining sun, and the temperature allowed to gradually decline at night, only keeping sufficient warmth in the pipes to prevent its undue recession, and to allow the top and bottom ventilators to be left open to a slight extent. This will insure a circulation of air, and prevent the deposition of moisture on the berries during the night. If the latter occurs the Grapes must inevitably spot. The border must not be allowed to become dry, affording the needful supplies of water on fine mornings when air can be freely admitted. After the Grapes are thoroughly ripe and finished, a temperature of

50° to 55° is necessary for the keeping of Muscats in good condition.

Houses of Thick-skinned Grapes.—Late Grapes generally require fire heat during the ripening period, so as to insure a circulation of air, and this they should have until thoroughly perfected. This ought now to be quite complete to insure sound keeping; where it is not the house should be treaced similarly to Muscats, with the difference that being mostly black Grapes, they must have a good spread of foliage over them. A temperature of 50° to 55° is necessary after the Grapes are ripe for the benefit of the Vincs, and the conditioning quality so essential to use in such varieties as Gros Colman and Gros Guillaume.

Cucumbers.—Autumn Fruiters.—Afford these every attention, supplying tepid liquid manure copiously. Remove superfluous laterals, guarding against an overcrowded growth; also avoid overcropping, not allowing the fruit to hang on the plants after it becomes fit for use, and take off staminate blossoms and tendrils. Maintain a genial condition of the atmosphere by damping the floor and paths in the morning, afternoon, and evening, syringing the plants only in the early afternoon of bright days. Look over the plants twice a week for stopping the shoots one or two joints beyond the show of fruit, removing bad leaves, and retain no more foliage than can be fully exposed to light. Earth up the roots as the plants advance in growth, only just covering them each time as they show at the sides of the hillocks or ridges, the soil being placed in the house some time previously to be warmed before used. Supply water as required, not allowing the plants to flag for lack of it, nor making the soil sodden by needless applications, always having it of the same temperature as the house.

Winter Fruiters.—Put the plants in large pots, plunging in a bottom heat of 80° to 90° until established; then raise them near the glass, maintaining a temperature of 70° at night, 75° by day, with an advance from sun heat to 85° or 90°. Where fermenting materials are used for bottom heat, they must be in preparation, throwing into a heap, applying water if necessary, and turning over to induce fermentation and dissipate noxious gases before making the beds. If plants have not been raised seed may be sown at the beginning of next month, and the plants from this sowing will produce fruit in February and onwards; but it is no use attempting to winter such plants without the

command of plenty of heat and a light structure.

Plants in pits and frames must be carefully watered, and only sprinkled lightly on bright days. The foliage should be kept thin, removing bad leaves and cutting out exhausted growths to give place for young bearing shoots, and close early with as much sun heat as is safe. The temperature may be increased to 95° or 100° after closing, and to secure a suitable heat at night (65°) and on duil days (70° to 75°) renovate the linings as necessary, and employ night coverings.

Melons.-When the latest plants are well up the trellis and showing fruit blossoms, these should be fertilised daily, the atmosphere being kept rather dry, and a little ventilation given constantly, so as to insure a circulation of air and prevent the deposition of moisture on the flowers. Stop the shoots at the time of impregnating the blossoms one joint beyond the fruit. When a sufficient number of fruits are set on a plant,

remove all the staminate and pistillate flowers, reducing the fruits to three or four on a plant, which must not be overburdened with fruit. Earth up the plants after the fruit is fairly swelling, and be careful in syringing the foliage, only using it lightly on bright afternoons, but maintain a genial condition of the atmosphere by damping the floors and similar surfaces in the morning and afternoon. Do not give too much water at the roots, but encourage root action by moderate moisture in the soil, with fresh additions of warm soil as the roots protrude. Maintain a temperature of 70° to 75° by day artificially, and 80° to 90° through the day from sun heat, with a night temperature of 65° to 70°.

In order to advance the ripening and enhance the flavour of late fruits maintain a brisk heat by day with enough ventilation to insure a circulation of air constantly, keep water from the house after the fruit commences ripening, and do not afford any at the roots, or only to prevent flagging. The October fruiting plants will be swelling their fruits, and must be assisted with tepid liquid manure whenever they become dry. Keep the laterals well in hand, also a sharp look out for canker at the collar, and rub quicklime into the affected parts until dry, and repeat as necessary. If there be any fear of cracked fruit cut the shoot or bine about half way through, a little below the fruit. This will check the flow of sap, but the chief cause of cracking is a hard rind acted on by a close atmosphere, causing the deposition of moisture on the fruit during the night. As a preventive of both canker and cracking ventilate freely and keep the air dry, and supply water sparingly at the roots.

Plants in pits and frames will not require further damping on the foliage, and should only have sufficient moisture in the soil to keep the leaves from becoming limp or flagging. The growths should be kept rather thin and the fruit well elevated above it—say on reversed flower pots, each fruit being placed on a piece of slate. Apply good linings, so as to finish the fruits satisfactorily, which requires a warm and dry atmosphere with free ventilation. After lining the beds a little air should be admitted constantly to prevent injury from steam.

PLANT HOUSES.

Crotons.—Well furnished plants that are to be increased in size may be placed into pots one size larger than those they now occupy. Plants that have become leggy may have their tops re-rooted, and these if properly treated during the autumn and winter will make excellent specimens early another season. All well coloured side shoots from plants that have been cut back may be rooted in small pots. These small plants will be found invaluable for furnishing purposes during the winter. Plants that it is necessary to increase in size should have a warm moist atmosphere, while those that are large enough and highly coloured may have a more airy position to prevent them starting again into growth. Those that are subjected to this treatment last much longer than others that are grown in a close moist atmosphere. A little chemical manure applied occasionally to the surface of the soil will be found beneficial to all plants that have their pots full of roots.

Allamandas.—The dwarf A. Williamsi will become a popular plant. It grows and flowers freely in a small state, and will, therefore, prove invaluable for decemetive purposes.

prove invaluable for decorative purposes. Well flowered plants can be produced in 5-inch pots. A. Hendersoni for supplying a large amount of bloom is certainly unsurpassed. Plants that have been growing and flowering for the greater part of the season should have liquid manure freely given them, or chemical manure applied to the surface every week. It is a mistake to allow the shoots to grow thickly together until they become crowded. This prevents the thorough maturation of the wood, and unduly shades the plants that are grown beneath them. The flowers on the plants are much smaller in consequence, and are often deficient in colour. Plants that are to be started early in the year should be kept drier at their roots, and slightly cooler after this month to harden and mature the wood. An early rest is essential if the plants are to start freely into growth when introduced into heat and flower early on short-jointed wood.

Stephanotis floribunda.—Plants that have made good growth and finished flowering should be subjected to cool airy treatment; in fact, the plants are better grown for some weeks without the aid of artificial heat. Give air liberally during the day when fine, but towards evening close or partially close the structure in which they are grown. Syringe the plants once daily to keep the foliage clean, and mulch the border or surface of the pots with manure to prevent evaporation. All weak growths may be entirely removed from plants that display a tendency to be crowded. Full light and plenty of air amongst the shoots are necessary to ripen and harden the wood, for upon its thorough matura-

tion the number of flowers produced another year will depend.

Gloriosa superba.—Plants that were started early into growth will show signs of going to rest. Keep plants in this condition drier at their roots, but do not unduly dry them. Water ought to be gradually withheld, and more air given until the growing stems have died away and the tubers are thoroughly matured, when they may be stored away in any place where the temperature ranges from 50° to 55° if kept dry.

Adiantum cuneatum.—Any plants that are intended for yielding foliage for cutting as long as possible should not be grown in a high temperature, and a liberal supply of air must be admitted to them. These plants have done well with us this year, and they have been grown for some months past in cold frames fully exposed to the sun. Fronds produced by this method are of the sturdiest description, light in colour, and last well in a cut state. Seedlings of both this and Pteris established in pans and boxes should be placed singly or two or three together in

small pots. If they are shaded and grown in a warm and moist atmosphere for a time they will soon become established and be very suitable for many forms of decoration. It will be necessary to harden them gradually before they are used. Spores of any kinds of Ferns may now be sown in pans or boxes, the surface of the soil need not be made too fine. After sowing cover with glass and place the boxes in a moist shady position.

shady position.

Caladiums.—Plants that have been in cool houses and are beginning to fade may be stored away to rest. Do not withhold water all at once. Place the pots containing the plants where the temperature will not range lower than 55° where they will be perfectly safe until they are required for starting again into growth. When sent to rest too rapidly and kept cool afterwards the tubers are almost certain to decay; they

should be well matured before they are finally stored away.

Poinsettias.—If properly treated these should be of the sturdiest description, and some care is needed not to excite them again into growth. Soft growth made after this period is seldom sufficiently ripened to produce large bracts of the finest colour. Very frequently a mistake is made when these plants are removed from cold frames by keeping them in too close and confined an atmosphere. Directly they finish their growth more heat may be given to develop their bracts. The same treatment applies to Euphorbia jacquiniæflora.

Ixoras.—Plants that have but recently flowered should have the most careful treatment. Their foliage must be free from insects, and the plants exposed to every ray of light possible to harden their wood before the winter. Plenty of air ought to be admitted, and a drier atmosphere maintained; but at the same time do not starve the plants, or more injury than good will result. Syringe thoroughly once a day.

APIARIAN NOTES.

USEFUL HINTS.

At this season it is perhaps desirable to warn bee-keepers against introducing queens, or joining swarms having two queens, rashly. I admit that alien queens can be, and are, joined to a hive safely without caging, and I could cite many cases where only a second or two expired between the deposing of the queen regnant and the introducing of an alien one which was well received; but the mishaps by reckless introduction which I am cognisant of are by far too numerous to warrant me in advising the introduction of queens without the use of a cage. It is the health and unmaimedness of the queen that is conducive to profitable bee-keeping, and in the absence of these a breakdown in the hive is sure to occur sooner or later, and at a time when the loss is irreparable. Therefore use every precaution before introducing queens or joining

swarms together.

The balling of queens is, in my opinion, entirely due to stranger bees; at least, I have never witnessed a case otherwise. There are different phases of balling, but the most prominent one is when the bees favourable to the queen discover one or more fractious bees they immediately ball her. If the disloyal bee or bees are kept outside the queen is safe, but if one or more get near her she is either maimed or stung to death. Therefore select a young queen and cage her for twenty-four hours, releasing her at dusk. Young bees at this season are doubtless not to be despised, neither are much older ones; both make capital stocks. It is the care and judicious management of these that determine our future success with either—not their age. One great thing with all queens is to take care and not stimulate these to breed at this season. All their strength and egg-laying power is best to be conserved till spring, the season that is most required for profitable bee-keeping.

If there is a paucity of bees in the hive containing a young queen, it rather taxes the powers of an aged one (intended to be deposed) to fill a few frames with brood, and place in the hive containing young queen intended for stock. Hives that require to be fed now, and not having a ventilating floor, should, immediately the feeding is past, have a clean dry board substituted, and, indeed, should be continued at intervals throughout the winter. A ventilating floor obviates all that, and conduces to having healthy

bees, and many of them.

ROBBER BEES.

Robber bees are now on the alert. Keep a strict watch over all weaklings, and contract entrances according to the strength of the colony. Be careful neither to spill about nor expose syrup nor feeders. These are the things that decimate the bees, and those who have for years advised the autumnal stimulative feeding of hives must have, in their ignorance of the proper management of bees, practised some or all of the above. For many years it has surprised me why bees required feeding in autumn to stimulate

breeding, when our own hives, as well as those in the whole district were overflowing with bees. A clergyman of my acquaintance used to say, "Instead of requiring to feed to cause breeding I would rather feed to reduce the population of the hives, as they are by far too strong."—A LANARKSHIRE BEE-KEEPER.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Solanaceous plant (Somerset).—Having seen a fresh specimen of the plant referred to last week, we are able to state that its name is Nicandra physaloides.

Cucumber Classification (J. McLeod).—If the disputants who aver that the Cucumber is not a vegetable will exhibit a brace in a collection of fruit they will receive a lesson that they will not be likely to forget — namely, the disqualification of the collection. There is no time for answering your other questions as we are preparing for press.

Stationary Chrysanthemum Buds (G. B. A.).—Cut off and burn all the tops that contain buds such as you have sent, and which have remained stationary for about six weeks. It is impossible they can develop. They contain a destructive enemy, microscopical drawings of which, by Mr. George Abbey, will shortly be published, and these, with the narrative pertaining to the discovery, cannot fail to prove of great interest to Chrysanthemum growers all over the world.

Tuberous Begonias (W. Clibran & Sons).—The box arrived as we are preparing for press. The flowers as a whole are very beautiful, but many of them had separated from the stalks, the names thus becoming detached. It was not so, however, with the single variety oculata, small, single, with a clear white disc, very distinct and pleasing. The double Golden Nugget is very rich and good. The names were separated from the others, and mixed indiscriminately, while the flowers were bruised and shaken through insufficiently close packing.

Planting Lilies of the Valley (Enquirer).—The advice to which you refer is sound. We have known them to grow very well when planted in the autumn, also in winter, but the weather may be such as to cause blanks and weak growth. The most extensive and successful cultivators take pains in the preparation of the soil, and plant when it is in the best planting condition in early spring. Flowering crowns are not the best for establishing permanent beds. The Victoria Lily is a fine variety as grown by Mr. Henry Hawkins at Twickenham.

Cider and Perry Refuse as Manure (J. W., Pershore).—One of the best of British gardeners who resides in a perry-making district says "the must or refuse from perry and cider mills is useless as manure." "Farmers," he goes on to say, "take care to keep cattle from it, or they would certainly eat it at great risk to life. There was a case last year of a pig dying soon after eating a quantity. It very soon goes to nothing on the land. Poultry are fond of scratching it over for the 'pips.' These germinate freely on the heaps the following season, and are planted out by some farmers to form stocks for grafting and budding. I have seen it used for mulching newly planted fruit trees, but it is not so good as short mauure."

Grapes Rusted and Shrivelled (Enquirer).—No matter how much water you have given the border, if it still remain dry, as you say is the case, it obviously has not had enough. It is impossible for any Vines to produce any other than small ill-coloured inferior Grapes in dry soil. If a thousand gallons are necessary for moistening the soil they must be given, and after the border is moist, not before, a liberal application of strong liquid manure would have a beneficial effect. We suspect also there has been errors in management other than letting the border get so dry, in respect to ventilation and general routine. You cannot materially improve the Grapes this year, but you may improve the Vines for future bearing, and this is necessary.

Kalosanthes coccinea (J. G.).—Water should be gradually withheld now and the plants placed in the sunniest position you can find. Flower buds will then form in the tips of those shoots that are strong The plants should be kept dry rather than wet through the winter. You ask if the "number of shoots should be reduced and the plants repotted" without giving an idea of the number and character of the growths or the size of the pots. Do not, however, shift them this autumn, and thin out any growths that are weak and crowded. This is all we can say in the absence of a description of the plants.

Celery Leaves Decaying (J. W. H.).—Although the green leaflets are spotted and the spots extend so as to destroy the tissue and leaflets are spotted and the spots extend so as to destroy the tissue and ultimately the stalk, there are no fungal threads surrounding the brown spots on the green part, nor are there any bacterial germs between the cell walls or in the cells. The stem with withered leaves is sound in the centre, but the cells below the skin or epidermis are quite empty, and as the cell walls are unpierced we conclude that the withering is due solely to evaporation. The spots on the green leaflets appear to have been caused by particles of nitrate of soda or some such substance resting upon them. Rust at the roots is generally caused by an excess of organic acids or the use of soapy manure at the bottom of the trenches. Rust in the leaves and stalks is caused by a fungus, but there is neither the Uredo nor Puccinia form of rust in the specimen examined. is neither the Uredo nor Puccinia form of rust in the specimen examined.

Withholding Water from Cattleyas (T. J.).—Water should be withheld grudually from these plants, beginning to do so as soon as the pseudo-bulbs are fully developed and display signs of ripening, and finally given only sufficiently often to keep the pseudo-bulbs from shrivelling. How long water can be withheld depends largely upon the house in which the plants are grown and the atmospheric conditions maintained as regards moisture. Simultaneously with a diminished supply of water at the roots and moisture in the atmosphere more light and air should be admitted to the plants. The Oncidiums you mention are only of slow growth; they do not under the best systems of culture appear to increase materially in size. We prefer to grow them in small baskets or pans, because they are less liable to suffer by an insufficient supply of water during the season of growth. If you place the plants in baskets do not take them off the blocks, but insert them into the baskets and fill in with fibry peat and charcoal in lumps. A little moss during the season of growth is also an advantage. We should advise you to leave them as they are until the spring. By Withholding Water from Cattleyas (T. J.).—Water should be We should advise you to leave them as they are until the spring. By no means should too much peat and moss be placed about the roots. These plants do best suspended moderately close to the glass.

American Baldwin Apple Trees (G. G., South Wales).—This Apple does not usually succeed in this country, except in warm soils and sheltered situations. It does well on the colite in Huntingdonshire where the soil is of a warm silicious nature with gravel beneath, and it would probably succeed in similar soil with a warm site in South Wales. The bushes are most likely to thrive, but it would have been better had they been on the English Paradise instead of the Crab stock. Trees on that stock do not transplant so readily as those on Paradise, but there is no danger of safe removal whilst the trees are young. Unless they have grown vigorously and do not ripen the wood well it would not be desirable to transplant them this autumn, though it may be done another year if you wish to check growth and induce fruitfulness. The tree intended for a standard ought to grow until it has formed a stout stem to the required height, and then have the top taken off so as to induce side shoots, keeping all but three at the upper part stopped with the object of strengthening the stem. Cut the stopped growths away in the autumn and shorten the three extension shoots to about 6 inches, then by taking two growths from each the following year the formation of the head will be laid.

Names of Fruits.—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (F. Jordan).—1, Quite rotten; 2, Rotten; 3, Beurré Diel; 4, Quite misshapen; 5, Rotten; 6, Winter Greening. It is essential that good sound typical fruits be sent, not blemished and decayed specimens. (C. J. F.).—Fearn's Pippin. (W. W. W.).—Warner's King. (S. W. Fitzherbert).—1, Cobham; 2, Blenheim; 3, character undeveloped; 4, Gloria Mundi; 5, Alfriston; 6, Trumpington, perhaps, but an imperfect specimen, the others fine. (A. H. L.).—1, Golden Russet; 2, Van Mons Leon Leclerc; 3, Bergamotte Esperen; 5, Napoleon. These names are approximate, the character of the fruits not being developed. (J. D.).—1, Beurré Clairgeau; 2, Summer Franc Real; 3, Rymer; 4, Cellini; 5, Greenup's Pippin; 6, Fearn's Pippin. (A. B.).—There is no character about the fruits sent. Some if not all are probably local seedlings, and never had names. Nor are they worthy of being distinguished and perpetuated. (Richard C. Long).—We are sorry to disappoint you, but it is impossible for anyone to name fruits accurately when their characters are quite undeveloped: The specimens you send, most of which are inferior, are weeks if not months from maturity. If the trees in your orchard are old several of the varieties will probably

not be worth naming. Those you send are, as a whole, much below average merit. Your object is a worthy one. By far the best way of improving the local fruit supply is to urge the planting of young trees of approved varieties in the best soil and positions available. (Andover).—Letter mislaid, but this reply will be recognised. The very large red Apple is Tibbit's Incomparable, and the Pear is a splendid specimen of Souvenir du Congrès. (J. U.).—Doyenné Boussoch. (P. M.).—1, Cox's Pomona; 2, probably local and worthless. (J. S. B.).—1, Pitmaston Duchess. The others are quite hard and will not be in condition for naming for some weeks. We have many times stated that Pears should be sent when showing signs of ripening, as flavour is a factor in determining their nomenclature.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. G.).—Silvery-leaved plant, Alchemilla sericea; berried shrub, Pyrus (Aronia) probably a variety of arbutifolia; trailing plant, Linaria Cymbalaria. (Tom Jones).—Gongora Loddigesi. (A. B.).—1, Impatiens Hawkeri; 2, Abutilon vexillarium. (F. D.).—Allamanda Hendersoni. (L. P.).—Æschynanthus cordifolius. (L. P.).—Æschynanthus cordifolius.

FARM HOMESTEADS.

WHEN the Scotch farmers came south after Essex farms, one of the first things asked for was additional farm buildings. They, at any rate, were fully alive to the importance of an ample provision of shelter for their herds if not for their flocks; they had it, and it must have contributed greatly to the success of their venture. In making such provision of outbuildings that are absolutely necessary a landlord enables his tenant to turn his holding to full account—aye, and to turn his live stock to full account also. To an able man the concession is positively more important than a reduction of rent, because it enables him to do his best with the stock-to afford it protection from cold and wet in winter, from extreme heat and flies in summer. If it were possible to obtain a return of the actual number of animals lost annually from exposure to wet and cold we have no doubt it would astonish everyone connected with agriculture. But though it is not possible the fact remains that losses do occur frequently, the cause being usually attributed either to black leg or to hoose, and probably with some truth, but exhaustion and low condition more often than not induce disease.

Early in the present year we had a complete set of new outbuildings erected for a tenant in time to be of use to him during summer. On a recent visit we were delighted to see a number of the best calves in the hovels that we had seen this season. They had never been out, but had been kept in and reared by the grazier's wife, and much credit are they to her. Nothing could be more satisfactory than their sleek, healthy condition. Home-bred and home-reared in the right way they are bound to prove profitable, such animals always being in demand; always commanding a price above, sometimes much above ordinary market rates. For another tenant who milks thirty cows a new house and set of outbuildings are to be built on a holding of about 200 acres. This farm is worthy of mention as a compact holding, recently arranged with an eye to general utility. Its lower boundary is in the heart of a valley by a road leading to a railway station, and the land stretches right up one side of the valley to the hill top, where there is connection with another public road. The rich grazing land in the valley is watered by a brook, and there are pools of sufficient capacity in the upland meadows.

In selecting the site of the homestead water was a primary consideration. A boring tool failed to reach water after several trials; the brook was therefore turned to, the necessary levelling showing that an hydraulic ram was practicable, so that by means of it and a filter bed the homestead will be well supplied with wholesome water, a matter of even more than usual importance, as this is a dairy farm, where cheese-making will be the chief thing. To avoid all risk of taint the dairy and cheese rooms will be on the north side, and the farmyard and outbuildings on the south side. On the ground floor there will be an entrance hall, having on the north side a sitting-room, behind which there will be a cheese-room, binding-room, and dairy; on the south side will be the kitchen, connected by a passage running past the larder to a back kitchen; and at the back of the house there will be a broad covered way from the back kitchen to the dairy. The upper floor will have six bedrooms, and will contain a bath-room; in fact all necessaries to form a comfortable, convenient house, without any superfinous rooms. Water will be laid on, drainage well done, and the

whey will go through a pipe from the dairy to a cistern by the

The outbuildings will consist of a cow house for thirty cows; this will be a span-roofed building, with a passage down the centre between the stalls. There will also be a loose box for calving, two calf hovels, four large piggeries, stabling for three horses, shed for store cattle, 18 feet wide, with the yard side open, a meal-room, chaff-room, granary, fowl house, and open shed for carts and implements. The cost of such a homestead depends mainly upon the building materials, which range from costly dressed stone downwards to simple s'ud and plaster, representing two extremes, only desirable under stress of local circumstances. There appears to be no material equal to corrugated iron sheeting for cheapness, utility, and durability. As roofing for a granary it is objectionable, because it becomes cool with such rapidity of an evening that the moisture of the warm interior air is condensed, and there is often so much dripping of water from the roof upon the stores as to become a nuisance.

WORK ON THE HOME FARM.

Frequently have we heard the remark that this has not been a favourable season for the use of "artificials." Our one failure was upon some pasture where, owing to the draining, the chemical manure could not be used till the drought had set in. But where it was used early it answered well enough for pasture, and its beneficial influence upon root crops was never more remarkable. Swedes, Mangolds, and Potatoes have all thriven wonderfully, and we were not surprised to hear from a correspondent to whom we recommended what we term our County Council mixture, that he has a crop of Potatoes of remarkable abundance, yielding a peck of tubers to a plant. With land made thoroughly clean now and ridged by double-breasted ploughs, we can next spring apply manure to the furrows, plant the Potatoes, and split the ridges over them, feeling assured that the soil is well stored with fertility. For Mangolds and Swedes the mixture may be sown broadcast after the muck is placed in the furrows, a top-dressing of nitrate of soda being applied after the plant is up and growing freely.

Lct yards, hovels, and all means of shelter for cattle for winter be now made ready for use next month. See that drains are in order, that the water supply is ample, and that the surface of all inner walls is limewashed. Litter is likely to be so scarce next winter that we advise all home farmers to collect all the tree leaves they can, to get bracken from the woods, and any sedges, rushes, or coarse grass that can be had. Reduce the head of stock well within reasonable limits; keep no unsound or delicate animals through the winter; calculate ways and means closely, and prepare for a long hard winter. If the weather proves mild and open so much the better; but a prudent man makes provision for the worst, and it is only in doing so that he can feel safe. We much fear that heavy losses of young stock are likely to occur in the coming winter, and so many are now in terribly low condition. We saw a herd of thirty or forty calves a few days ago that had been bought cheap! All of them were "bags of bones," and hardly any of them are likely to live through the winter.

9th.—Bright sunny morning, but more or less dull during morning, fine afternoon and evening.

Another generally fine week, with the temperature even higher than in the previous one, and considerably above the average.—G. J. SYMONS.

OT for many years past has such a favourable season for growing Tomatoes in the open air been experienced as during the summer now drawing to a close; and never probably has such a collection of varieties, or selections, been seen fruiting together as in one of the trial grounds of Messrs. Sutton and Sons, Reading. Nearly 200 reputedly distinct sorts, obtained from various sources in this country, also from France and America, have been grown under absolutely identical conditions from beginning to end, the collection forming a veritable museum of the beautiful, wholesome, and popular esculent. The plants have been thoroughly well grown, too, throughout their career, with the object of developing to the fullest possible extent their leading characteristics; and it has only to be stated that twelve plants represented the minimum number of any variety, while of some there were at the least five times that number, to show that there were thousands in the aggregate, the whole forming something like a forest of sturdy tree-like plants laden with scarlet, crimson, and golden fruit.

There were, it may be truly said, Tomatoes of all colours, shapes, and sizes yet produced, from the miniature Currant varieties, with elegant drooping racemes of coral-like berries or yellow beads, to the huge corrugated American monsters, weighing 1 lb. or more. Mentioning these it may be well to dispose of them at once. However they may be valued in the land of big things they are clearly out-distanced according to our standard of merit in Tomatoes by varieties which have been raised at home, or at least improved by rigid selection. There is not one of the newer Americans that is worthy of a place by the side of our best varieties, while most of the older introduced sorts which did good service in past years are out of date. However much we are indebted to our transatlantic friends for teaching the value of Tomatoes, and leading the way in their popularisation, also furnishing us with improvements on the old stock, we are now undoubtedly in advance in the question of varieties, and growers who want the best obtainable have no occasion to go out of England for them. That is a fact which no one can gainsay who has examined carefully, and without prejudice, the great Reading collection.

What there is in store for us from the "other side" time alone can tell, but we do not want varieties of rampant growth which concentrate their resources on one or two unwieldy corrugations, leaving a residue of clustered deformities in the struggle for existence. We rather covet plants of sturdy habit and prolific in smooth firm fruits, uniform in character from base to summit. If large fruits are wanted for exhibition they can be had by a good choice of English varieties, and such cultural methods as successful growers adopt in thinning and supporting the crops. If mediumsized produce is preferred for market, say averaging about half a dozen fruits to a pound, there is no difficulty in obtaining them, nor is there any lack of small-fruited varieties for ornament and use, or both combined. Plenty could be found for all purposes in the great trial in question, as good, it may be safe to say, as could be procured from any part of the world, and whatever our shortcomings may be in other respects, it is at least satisfactory to feel that England is in the ascendant with Tomatoes.

Some catalogue illustrations that are published of plants bearing

clusters of fruit close to the ground are regarded by many persons as exaggerations, and allegations have been heard of such plants growing only in the artist's brain. No doubt many hundreds of persons have had the pleasure of inspecting the collection under notice, and they would have no difficulty in finding row after row in which the plants were bearing huge clusters of fruits so low down that it would be difficult to place the hand under them without its coming in contact with the soil. That habit of bearing was not the exception but the rule with some of the varieties, notably Exrliest of All, which justifies its name, and Main Crop, the bulk of the clusters of large handsome fruits on this sturdy grower being produced on the lower part of the stems from just above the ground to a height of 2 feet. An acre of such plants and crop would be worth at least £100 if the produce were sold for 2d. a pound. Both those are outdoor varieties of sterling merit when well grown during a favourable season, and there are not many seasons in which the fruit of the former especially would not ripen outdoors in appropriate positions if the plants were rightly prepared and managed. Errors in either or both those respects are accountable for many breakdowns with Tomatoes outdoors and under glass as well. Of that there can be no manner of doubt, but it is one of the most difficult things in the world to make many of those who fail believe it, and so much the worse for them. They honestly think that everything which could be done has been done when the plants or crops have failed, and are also thoroughly convinced that whoever had attempted the work in the same house or outside plot the same season must have failed also. very much mistaken. Half the failures with Tomatoes even outdoors are the result of mismanagement, and a great deal more than half of those under glass are brought about by the "cultivator." The sounder the methods of cultivation the less the liability of the plants to fungoid, bacterial, or any other attacks.

In all the thousands of plants at Reading there was scarcely a failure, except in some inherently weak varieties; and if a plant here and there of the strong should have "gone off," and been found full of bacteria, while those near and all around remained healthy, the victim would have been probably planted with the roots either too dry or the soil in the pot a soddened mass. Many a so-called mystery is traceable to a simple cause, and so-called small mistakes often lead to great losses. As with individual plants so with a houseful. Make an initial mistake, and the seed is sown of ulterior collapse. The plants, when microscopically examined, are found eaten up by some parasite or micro-organism, and the fiat goes forth that these are the cause of the trouble. No; in most cases they were the results of some cultural mistake. The plants were brought into a condition favourable to seizure, and were seized. Microscopists who are not cultivators may not admit this dictum, but cultivators who are microscopists take care not to condemn it; on the contrary, they urge the best of culture for preventing insidious attacks. Why were the Reading plants so healthy and so heavily fruited down to the ground? Because no mistake was made by the grower, and the climatic conditions were favourable to their prosperity. Under glass the climate is very much what man makes it when he has the means at command, and outdoors, though he must take the climate as it comes, he may enable his plants to withstand adverse conditions by good work in preparation, or render them liable to failure through erroneous methods.

The Reading practice is very simple but very sound. If the cultivator were asked to describe it he would probably begin with a few negatives: - "Do not raise the plants too early and grow them tall and tender for planting out, as if you do you will only at the best get a few trusses of fruit at the top of lanky stems. Do not add fresh manure to the ground in spring, but give what is needed in the way of enrichment in the autumn, then the soil will be fertile yet sweet at planting time. Do not plant deeply to make tall plants look a little sturdy or to save stakes. Do not let lateral growths extend, but pick them out as soon as seen to

concentrate the resources on the main stem-leaves, and fruit, and do not top the plants till they attain the required height."

After telling you what not to do, he would, in his quiet firm way, tell you what he does, and what others should do. "Sow thinly about the middle of March, and keep the plants growing steadily and sturdily close to a glass roof, so that they will have short jointed stout stems and thick leaves. In due time gradually inure them to the full exposure for which they are intended, and which they should endure without a leaf suffering. Have them dwarf when planted out towards the end of May, or when the weather is safe, with the leaves resting on the ground, and they will be ready for work forthwith. Though the plants are stout enough to stand alone, yet as stakes will be needed provide them at once, and there will be no root disturbance. See that every plant is in the right condition as to root moisture, neither too dry nor too wet, and plant shallow. The roots should be in the warmest soil, and the deeper they are sunk in the ground the colder is the medium surrounding them. We want them to start growing at once, not stand as if paralysed for a month, thus losing precious time that can never be regained. Forcing the growth under glass too early in the season, to be chilled and checked later, is exactly the wrong way; it is a bad beginning, and we have no right to expect it can lead to a good ending-healthy plants bearing full crops of fruit for ripening as soon as the weather will permit." Such in effect is the routine, and it will be conceded that it embodies sound cultural principles, and it certainly answers well. The plants are grown a little more than a foot apart, in rows 3 feet asunder, across a series of long narrow beds. Each plant is confined to a single stem, and topped at a height of about $3\frac{1}{2}$ feet, no laterals being allowed to extend, and, as producing stem-leaves, and fruit alone, there appears to be no overcrowding, though some of the robust varieties were evidently not amenable to such restricted culture in this country.

The collection is grown, like collections of everything else by Messrs. Sutton & Sons, for testing varieties by comparison, selection, and elimination. Those that succeed the best are retained, come from whence they may, and endeavours are constant for improving by selections from the best, and not without success. For instance, there are several stocks or strains of Earliest of All, but one stands out clear as the first and in every way the best, four tiers of the huge clusters of fruit being completely ripe, the next nearest having the fourth cluster changed, but not ripe. Bell's Defiance appears to be a good type of the variety named, but not quite so early as the best selection. Then we have what seems an absurdity in terms—an improvement on Perfection, the fruits being deeper than those of the type, and the handsomest for exhibition; it will simply supplant the old form, and not presumably be invested with a distinguishing name. "Perfection" means something absolutely complete, not open to the smallest improvement, and the term "degrees of perfection" too commonly used ought to be abolished. Returning to the varieties, for size and beauty of fruit with productiveness Magnum Bonum, perhaps, bears the palm, and it is undoubtedly a Tomato of high excellence, also early. A1, too, is a noble and beautiful fruit, and the crop was a valuable one. The three last named varieties, with Main Crop, form a quartette of Tomatoes which it would be hard to excel in size, symmetry, and brightness of colour.

But there are smaller red Tomatoes of note, of what may be termed the Prelude type, as bearing the fruit not so much in bunches as long racemes, but Prelude is too small. Abundance excels it in being larger, and growers who desire a great abundance of medium-sized fruits for market may have them in this variety. Conference partakes of this type in part, but the very bright and rather small fruits are borne more in clusters. Not so those of the comparatively new variety, Sutton's Dessert, for the scarlet Plumlike fruits hang in distinct racemes a foot long. The plants were objects of beauty, and Tomato connoisseurs who enjoy the fruit in an uncooked state will have a treat in this distinct variety.

Amongst the large fruited yellow Tomatoes the handsomest was

perhaps Golden Perfection, in size and shape the fruit being exactly like its scarlet precursor. It is more appropriate for growing under glass than outdoors, and for weight of crop in the open it did not by any means equal Golden Queen, of which handsome fruits were bountifully produced. One more yellow Tomato must have mention, the smallest of all, but charming in appearance and excellent in quality, Golden Nugget. No one could see the plants of this variety without being impressed by their beauty. The fruits are like Golden Gage Plums, but brighter, and it was not in the least difficult to find from twenty to thirty in a branching cluster. The plants were laden with them, those on the fourth cluster being quite ripe, a sufficient indication of earliness. A number of such plants in the London or any other parks or gardens would create something of a sensation. Berry-bearing plants are grown for decorative purposes under glass, and certainly those of this golden-berried Tomato were strikingly ornamental in the open air. This variety has received the maximum number of marks of merit at Chiswick, and like the scarlet dessert sort above noticed, is a distinct acquisition. The collection included a number of other meritorious Tomatoes that cannot be named. Such complete trials as the one in question, in which every variety receives the best possible attention, are decidedly instructive and worthy of recognition. -AN OLD GROWER.

SUMMER BEDDING DURING TROPICAL WEATHER.

THE summer of 1893 has been an ideal one for flower gardening in all instances where good facilities for watering were provided and made use of, but a disastrous one in those places where water could be only sparingly given. Where the plants have been grown under the most favourable conditions the majority of them have done remarkably well, and an unusually long season of beauty has been secured. Planting was accomplished early, and at the present time (September 9th) the beds look brighter than I previously

remember them to have done at the same date. This satisfactory state of affairs is doubtless due, in a great measure, to the absence of heavy rains, which frequently start the plants into strong growth never remarkable for floriferousness. This is particularly noticeable in the case of Pelargoniums. At no time throughout the summer have they made growth rapidly; indeed for some time after planting the weather was so tropical that with the best attention in the way of watering they were longer than usual in establishing themselves, but from the time they began to flower freely till now the best varieties of Pelargoniums have provided a continual display of attractive colours. Large trussed varieties like Henry Jacoby and John Gibbons have exhibited their true form; plenty of sunshine and an almost entire absence of rain favoured the full development of their enormous trusses, which are undoubtedly attractive. Although I like these bold trussed Pelargoniums, I am also fully alive to the great value of the older varieties which bear a profusion of flowers, though the trusses are small, for in dull or wet seasons these often make the best display. As a bright scarlet I think there is none to eclipse Vesuvius. Indian Yellow is another splendid bedder which for years to come will keep alive the memory of Donald Beaton, its gifted raiser. Large masses of this seen from a distance have a unique and beautiful appearance, and its attractiveness is by no means diminished on closer inspection. I know of no other bedding plant which produces flowers of so peculiar, yet pleasing, a shade of colour. This was recently described to me by an artist of repute, as a true Indian pink.

Among Ivy-leaved varieties Madame Crousse still holds the foremost place, making as it does good growth under conditions not favourable to many plants, and producing at all times abundance of flowers. The past season has suited it exactly, and four large beds in the flower garden are still one mass of salmonpink colour. I find Mrs. Clibran Tropæolum, or Golden Harry Hieover Pelargonium, form effective edgings for beds planted with this variety, the slight lilac tint in the flowers is then shown up to advantage. Two beds of Souvenir de Charles Turner, edged with a broad band of Mrs. Perry Pelargonium, were attractive early in the season. The bold trusses of deep rosecoloured flowers borne by the plants in the centre of the bed exhibited a marked contrast to the silver variegation of the edging. There is, however, I think, no comparison between Madame Crousse and Souvenir de Charles Turner Pelargonium; the former

flowers freely all through the season, the latter grows strongly but

blooms only sparsely after the middle of August. I have this year discarded Mrs. Pollock in favour of Black Douglas on account of the more distinct bronze zone in the leaf of the latter. If a golden variety were required I should give the preference to Crystal Palace Gem. Those who have some difficulty in raising a sufficient stock of Lobelias from cuttings will do well to obtain seed of Sutton's Dark Blue, which I have this season tried with results that exceeded my expectations, the plants being so uniform in both colour and habit as to leave little to be desired.

After the brilliant sunshine experienced throughout the summer we might reasonably expect to hear of many failures with Violas, but we are happy to record the fact that our own have continued to flower for a longer period than they did last year. They have, however, received enormous quantities of water, and unremitting attention in the removal of faded flowers. This, together with sweet rich soil and autumn or early spring planting, are the true secrets of success in Viola culture. Two long beds of Countess of Hopetoun (white) edged with a broad band of Lobelia, have throughout the summer been extremely effective. Another hexagon bed planted with Viola Yellow Boy, edged with Lobelia and dotted opposite the angles with single plants of Heliotrope Miss Nightingale, the centre being occupied with a Chamærops gracilis, supplied a novel and pleasing combination.

Among annuals the French Miniatum Marigolds have been unusually good. Orange and Queen of Dwarfs I can strongly recommend. The colours are very effective, and they flower splendidly until the approach of frost. A fine pink variety of Phlox Drummondi having a white eye is excellent for planting in large masses. Cornflowers, Stocks, Zinnias, Gaillardias and Dianthuses have all rendered material assistance in keeping both beds and borders gay, as well as in supplying cut flowers. Asters have unfortunately been to a great extent a failure, the plants being attacked by a minute fly in the early stages of growth, and where insecticides were not speedily applied the subsequent growth was unusually weak, and the flowers as a natural result small. Notwithstanding a few failures, I am inclined to the belief that the flower gardens of Britain will be long remembered for the brilliant spectacle they have presented during the last three months.—H. Dunkin.

PEARS VERSUS PEACHES.

"Pears are infinitely better and more profitable than Peaches, and we are therefore going to substitute the former for the latter on all the suitable wall space in the garden." Thus remarked a wellknown gardener to me a few weeks ago, and judging by the appearance of the trees to which he pointed with evident pride he would be perfectly justified in carrying out the proposed change. The young Pear trees planted three years ago against a wall with a south aspect were in vigorous health, bearing large stout foliage and a heavy crop of magnificent fruits. The latter were swelling rapidly, because they had been thinned and copious supplies of liquid manure with ample surface dressings administered during the hot weather. Pears of this kind are a credit to the grower, are appreciated at the table of his employer, and if disposed of in the market at a suitable period when there is no glut would doubtless realise handsome prices, and prove a remunerative investment. Such a testimony could hardly be given the outdoor Peaches. The trees were old and weakly, having been grown in their present position for perhaps thirty years, and during the greater portion of that time had, according to my informant, failed to ripen the wood or fruit properly. This season, of course, has been an exceedingly good one for Peaches on walls, and in the case mentioned the facility of the course of the co tioned the fruits although small were ripening early in August. But this is an exception to the rule, and in all probability will not occur again for some time, hence the gardener to whom I have alluded still remains firm as regards his decision to substitute Pears for Peaches.

Opinions vary, according to experience, as to whether Peaches can be profitably grown on walls without the aid of glass, and it is quite probable that among the numerous readers of this Journal there are many persons who are quite ready to take up the cudgels on behalf of this fruit. That good Peaches can be, and are, grown on open walls in various parts of the country will be readily admitted, and this, too, in spite of adverse seasons. To my knowledge there are gardens where it is a rare occurrence for the open air Peach crop to fail, no matter what the weather may be; but these, it need hardly be said, are situated in warm favoured localities. Much, no doubt, depends upon the treatment given to the trees and the soil in which they are growing, but instances could be mentioned where, under the best management, failures generally accrue, primarily through local surroundings and climatic influences. In such cases, therefore, one might wisely do away with the Peaches and plant Pear trees in their stead,

and the results, in nine cases out of ten, would be of a satisfactory nature.

To illustrate the various opinions regarding this subject, a few cases in point might advantageously be cited. In response to a question as to the advisability of growing Pears in preference to Peaches on walls in the open air, a gardener, who has charge of one of the finest gardens in Yorkshire, wrote me as follows:—"I cannot understand anyone in the north attempting to grow Peaches on open walls when glass can be put up so cheaply. The Peaches on open walls when glass can be put up so cheaply. the walls in these gardens did not pay for the labour of nailing. In 1887 the Peach wall (a long one) was covered with glass—in fact, a house 11 feet wide was erected, and since then it has been heated. I have kept an account of the produce sold, which has now more than paid for the whole outlay. Had the Peaches been on open walls the returns would have been nil. I think Pears would pay better on south walls, but then one must not grow many -something to please the eye is necessary. ence is that nothing would pay better than Pitmaston Duchess. This variety is a good cropper, fruit large, and of excellent flavour; one has no difficulty in making 6d. each of first-rate fruit. Clapp's Favourite is another good showy Pear I can strongly recommend for the purpose." From the foregoing it will be seen that in this instance Peaches are preferred so long as they can be grown under glass, and then they prove remunerative, so much so as to pay in less than five years for the outlay of erecting a house nearly 100 yards long. Against this it will be noticed that Pears are recommended as being the more profitable on south walls, and many gardeners who are struggling with Peaches in the open air in northern or unfavourable districts will do well to bear this in

To go further afield, a case in Northumberland might be mentioned. Some years ago perhaps one of the finest Peach walls in the country could have been seen in the gardens at Howick Hall, about forty miles north of Newcastle-on-Tyne, and situated on the coast line. The wall is, or has been, heated by flues in the old fashioned way, and many years ago, I am told, grand Peaches were grown there. For a short period the trees were partly under my charge, and in 1887, the last season I saw them, the fruit ripened fairly well, and the earlier varieties coloured beautifully. These, however, were by themselves in that respect, for although the flues were sometimes slightly heated when dull weather prevailed, the later varieties failed in ordinary seasons to ripen the fruit properly, and the wood seldom finished as it should have In consequence of this a change was proposed by Mr. Inglis, the gardener, and Pears were substituted in the place of some of the Peaches. This took place in 1887, and since then no doubt more Pear trees have been planted against the south walls with good results. In connection with this it may be mentioned that whilst there I, acting under instructions, cut down several old unfruitful Pear trees, and in the spring of 1887 Writing me in February grafted the stocks with other varieties. Writing me in February last year Mr. Inglis said, "You will remember grafting a Conseiller de la Cour (Maréchal de Cour) on the stocks against the south wall. Last autumn, 1891, I gathered from those same grafts fruits weighing 15 oz -. each. I also had Pitmaston Duchess weighing 18 ozs., which I consider good for the far north." Fruits of this weight are unquestionably good, and are, moreover, a credit to the grower. There is at Howick a remarkably fine collection of hardy fruit, and, notwithstanding the obstacles with which northerners have to combat, Mr. Inglis can always manage to make a splendid display with his Apples and Pears. Should this meet his eye, as it probably will, a few remarks from his pen as to "Pears versus would no doubt be appreciated by numerous readers of Peaches' the Journal, some of whom, perhaps, are not quite so successful in hardy fruit culture in a northern county.

Coming south one might also enumerate numerous instances where Peaches on walls in the open air are by no means a success, and Pears are being planted in their places. One case in this latitude will, however, be sufficient to prove that no apology is necessary for bringing forward the subject. At Cadland Park, situated on the shores of the Solent, and where the soil is light and warm, the Peaches for the most part on open walls this year, as they have been apparently in previous seasons, are a failure. The trees a few weeks ago when I saw them were comparatively leafless and the fruit was poor compared to that grown in unheated houses. I would hasten to add was not the fault of the grower but rather that of the climate; and as before mentioned in these pages, Mr. Garner, on taking charge in the spring of the present year, with the tact of a good gardener, wisely decided "to do away with the Peaches" that were growing on a wall facing south east and plant Pears. The trees were crippled owing to the fact that during March and April the leaves, being exposed rather to the east winds, usually become badly blistered, and thus the crop is annually affected. If this occurs in a season like the present when there were but few cold easterly winds, it will be easily understood what the condition of the trees must be under ordinary circumstances. Pears in such a position would not suffer to this extent, and others who have Peaches under their charge that do not flourish so well as is desirable owing to an unfavourable site might also consider the advisability of growing Pears in their stead. On a wall facing due south at Cadland Park, Peaches, it might be mentioned, will thrive, and on such it is proposed to grow them. The surroundings in this position are exceptionally favourable to their growth, and as in other southern gardens near the coast success in their culture generally accrues if the trees are judiciously

managed, and they are protected from cutting winds.

Apart from the value of the fruit produced from Pear trees and their adaptability for general cultivation, there are other points which might be taken into consideration. Peaches are here to-day, and to-morrow they are gone. In other words, the fruit cannot be kept, after becoming ripe, for much longer than a week except in an ice house, and then at the risk of losing its flavour. It matters little how large a collection of Peaches is grown on the walls, the season of ripe fruit cannot be prolonged beyond September. Pears it is quite different. A good wall devoted to Pears of early, midseason, and late varieties will give a succession of choice fruit from August till May inclusive—a period of ten months. What more could be desired? Looking at the matter from all points, it will thus be seen that Pears weigh heavily in the scales against Peaches in more ways than one, and those who are responsible for the production of fruit of the highest quality will do well to investigate the subject. Some readers may be inclined to think that I am advocating the non-culture of Peaches in the open air, but such is not the case. What I maintain is that in many gardens a large amount of wall space is devoted to Peaches that might more profitably and creditably be given up to choice Pears. The former in ordinary seasons are, as a rule, a failure, or nearly so; but the latter would, under judicious management, invariably result in producing an abundant crop of high-class fruit. Where Peaches can be successfully grown in the open air by all means continue their culture, and if plenty of wall space is forthcoming Pears as well may be cultivated; but when the space is limited and the Peach crop uncertain, I should unhesitatingly advise the growth of Pears on south walls. Much more might be said in support of my contention, but the experiences of others would be interesting before proceeding further.—C.

AUTUMN TINTS AT HAMPTON COURT.

HISTORICALLY, perhaps, Hampton Court Palace is as interesting as any public place in or near the metropolis, and for this reason it is a popular resort for Londoners. As is generally well known the Palace and its pleasant grounds are situated on the banks of the River Thames at a distance of about fifteen miles from London, and during the summer thousands of people go there by boat and rail, the latter starting from Waterloo, being the speediest method of travelling. If the visitor enters from Teddington he has to pass through a celebrated avenue of Chestnut trees in Bushey Park, and these when in bloom form a most pleasing sight. The same applies to the whole surroundings in the autumn, for at the present time the leaves of many trees are assuming tints of various hucs that cannot fail to attract the attention of everyone who is interested in Nature.

There are many things to be seen at Hampton Court, and of these the horticultural department is by no means the least important. Summer is doubtless the best time to pay a visit to the beautiful grounds, for then the bedding is at its best, and in this respect Mr. Graham, the superintendent, can hold his own. His skill has for so many years been conspicuous here that no one looks for other than good taste in the arrangement of flowers and plants at Hampton Court, and this fact is known throughout the country. This year there is no exception to the rule, and although my visit this season was inadvertently delayed until Monday last, there was then much to note in the way of good bedding. The summer flowers are for the most part over, but the numerous autumn tints are quite as interesting if not so showy, and if some of the beds at the end of September are past their best it can easily be seen that they were really beautiful carlier in the season.

The principal bedding is to be seen in the public pleasure gardens which are situated in front of the Palace. These are about seventy acres in extent, and between them and the building is a magnificent terrace or gravel promenade which is at least half a mile long and 36 feet wide. Parallel with this are two borders filled with miscellaneous plants, and on the opposite a continuation of beds of various shapes and sizes. The borders alone are worth a visit, for they contain many fine masses of plants, the arrangement of which is consistent with other good features about the place. One of the borders is devoted to hardy plants and the other to sub-tropical bedding. The former just now is very gay with clumps of Helianthuses, Phloxes, and Dahlias, the front part being occupied by a row of Crystal Palace Gem Pelargoniums with an edging of blue Violas and Dactylis glomerata variegata planted alter-

nately. The blue flowers of the Violas form a pleasing contrast to the variegated Grass. The wall at the back is covered with Clematises, Roses, the Canary Creeper (Tropæolum canariense) and other climbing plants. The sub-tropical plants in the other border are likewise well arranged, and form quite a feature in themselves.

Among the beds opposite the borders alluded to are some very choice arrangements. During the present year I have seen many beds in public and private gardens, but few to surpass those under notice. Notwithstanding the dry season the plants have flourished well and bloomed profusely, the Pelargoniums being especially fine. Tuberous Begonias have apparently been ladened with bloom, which is rather an exception to the rule this year, and they are yet yielding an abundance of flowers, bright and rich in appearance on a dull autumn day. A large oblong bed near the entrance from the Kingston Road, at the left end of the terrace, is particularly showy. This is filled with miscellaneous plants, which include three large Abutilons with rich yellow foliage, Zea japonica variegata in the centre, the remainder of the bed being occupied by Matigolds, Stocks, Zonal Pelargoniums, and Zinnias. The last named plants are remarkably good, the blooms being fine and brightly coloured. An edging of Alyssum maritimum variegatum and Echeverias complete the arrangement. Close by a bed of Abutilon Thompsoni, with Petunias, Ageratum, and an edging of Gnaphalium lanatum makes a good display; and the same may be said of early flowering Chrysanthemums, which occupy a square bed, as well as other places.

Some other beds of different shapes, and borders are not by any means unattractive at this period. One border filled with standard Roses, amongst which Cannas, Dahlias, and single Petunias are planted, is specially pleasing. Two beds of Roses with a groundwork of Lady Molesworth Heliotrope, a fine dark variety, are deserving of notice, not for their brilliant appearance, but the delightful fragrance they emit. A bed composed of scarlet Pelargoniums (Vesuvius), with a row of the variegated Manglesi next to an edging of Cannell's Dwarf Ageratum shows up conspicuously. The Ageratum is one of the brightest blues I have seen, and besides being dwarf is very floriferous. A small collection of succulents tastefully arranged commands attention, as also do the groups of foliaged plants which are placed in the turf.

Another bed that is exceptionally bright for the autumn is one filled with a variety of plants. The bed is oblong in shape, and in the centre are three Dracænas, around each of which is a ring of Coleus Verschaffelti. The centre ring is filled with double scarlet Pelargoniums laden with blocms, and the others with Mrs. Pollcck Pelargoniums. Between the rings are some Marguerites, Fuchsias and Begonias, all flowering grandly. An arrangement of white Tuberous Begonias and pale blue Violas with an edging of Echeverias is noticeable for its chasteness rather than brilliancy; and several beds filled with blue Violas and Flower of the Spring Pelargoniums, with Iresine Herbsti for an edging, also command attention. Begonia Worthiana (tuberous) is a favourite plant here, and it is seen to advantage in several beds. The centre of one large bed is filled with this Begonia covered with blooms, and these show well against a margin of Coleuses and yellow-leaved Pelargoniums. As an edging to some of the borders Begonia Worthiana is also used, and for this purpose it is admirably adapted. Among the numerous Zonal Pelargoniums used, Tom Bowling is most conspicuous, the large trusses of this variety being very showy.

A word must be said in regard to the carpet bedding. This is not practised very extensively, and perhaps wisely, but it is done well. The designs are excellent and clearly defined, the plants being kept well within bounds. Carpet bedding is usually seen to advantage in the autumn when many of the flowering plants are past their best, and such is the case at Hampton Court. A long spell of hot dry weather brought out the colours of the Alternantheras and Coleuses to perfection, besides being conducive to a sturdy growth. One huge bed is laid out in squares, each portion being occupied with a different kind of plant. Alternantheras, Echeverias, Mesembryanthemums, and other plants generally employed in carpet bedding are used, and the whole forms a novel feature. There are, I believe, about sixty squares in the bed. Another carpet bed with a Maltese cross of Echeveria Peacocki and Sempervivum montanum in the centre is particularly good, and the other portion of the design being worked out by Alternantheras in variety, Mesembryanthemum, and Echeverias.

In addition to the principal borders, to which allusion has already been made, there are others which deserve more than a passing notice. One filled with Dahlias, early flowering Chrysanthemums, and Aster bessarabicus is remarkably showy for the time of year, and it is worthy of imitation. The Dahlias at the back are full of flower, the same applying to the white and cream coloured Chrysanthemums, whilst the edging of A. bessarabicus is literally one mass of bright purplish blue blossom. It is almost impossible to form a more attractive border in the autumn, and such might well be seen in every garden.

Much more could be said in regard to these beautiful grounds, but space forbids further details. These notes would, however, be even more incomplete than they already are without a reference to the famous Black Hamburgh Vinc. This at the present time is showing signs of autumn, for more than half of the large number of burches which it has borne this year have been cut, and the leaves are beginning

to put on their autumnal tints. The bunches are medium in size and very even, whilst the berries are large and well coloured. The noted Orange trees, too, which stand on the terrace at one end of the palace have a history which is interesting to many visitors. The trees are in huge tubs, the majority of them of a healthy appearance, and some producing fragrant blossom. - OBSERVER.

ORCHARD PLANTING NEAR DENVER.

To your many readers who are connected directly or indirectly with horticulture, the following account of what is now going on around this city will doubtless be interesting as showing the large and effective scale on which fruit tree planting is conducted in Colorado. I have previously said that so recently as 1863, William Lec, a native of Croydon, Surrey, England, planted the first Apple trees in Colorado, a few miles from the then frontier village of Denver, having brought them by waggon 700 miles across the plains from Iowa City, Iowa, the then nearest railroad point. To-day Denver has over 150,000 inhabitants, and is the centre from which radiates a system of railroads aggregating 26,893 miles, while there are at least 12,900 acres already planted with fruit trees in Colorado, and the area is annually being increased. For instance, about eight miles south-east of Denver one company in the spring of 1892 planted 48,000 standard fruit trees, besides Blackberries and Raspberries, on 540 acres, and this year the same company planted 35,000 standard fruit trees, and 112,000 Blackberries and Raspberries, on an adjoining 450 acres. The land is laid out in 5 acre tracts, each containing approximately 421 trees, viz., 210 Apples, 135 Pears, 10 Cherries, 50 Plums, 16 Prunes, 10 Apricots, besides 10 Grape Vines, 625 Raspberries, and 625 Blackberries.

The trees comprise only varieties which years of experience have proved suitable and highly profitable in the vicinity of Denver, such as:—Summer Apples, Yellow Transparent, a Russian variety. Autumn Apples, Alexander, Haas or Fall Queen, a variety which originated near St. Louis, Missouri; Jeffries, a splendid variety of Pennsylvania origin; Red Beitingheimer, a German sort, very large and beautiful; and Wealthy, which originated near St. Paul, Minnesota. Winter Apples, Babbitt, a "coming Apple," originated in Illinois; Jonathan, McIntosh Red, Pewaukee, originated in Wisconsin (raised from the Duchess of Oldenburg), Shackelford, which a few years ago took the first prize at the Illinois State Horticultural Society as "the best new Apple," and is said to be the best market Apple produced in Colorado up to this time. Tolman's Sweet, Wagener, Walbridge, and Wolf River.

Pears.—Bartlett, Duchesse d'Angoulême, Louise Bonne de Jersey, Beurre d'Anjou, Flemish Beauty and Mount Vernon, a new American Pear, the very best of its season, a seedling of Winter Nelis. Cherries.— Early Richmond, Ostheimer, a late Cherry taken from Germany to Spain in 1814, and brought from there to Kansas; small trees of this variety near Denver have borne two quarts of Cherries each in less than fourteen months from planting; Montmorency Ordinaire, Suda Hardy, a very late variety originated in Louisiana. *Plums.* — Imperial, McLaughlin, Shippers' Pride, Early Red, and Lombard. *Apricot.*—North American. *Grappes*.—Moore's Early and Worden. To the south of Denver 370 acres of land were planted this spring with 26,000 standard fruit trees, 30,000 Raspberries, 32,000 Blackberries, and 1000 Moore's Early Grape Vines. A few miles east of Denver, 260 acres (reached by electric street car line, and having water mains, school, and electric lights) are being planted in a similar manner, and 580 acres adjoining will be planted by the same persons next spring. On the same avenue another 160 acres has been laid out in 5 acre tracts for suburban homes, and is being planted with standard fruit trace. Blackbarries and Basebarries as above, together, with 2000. trees, Blackberries and Raspberries as above, together with 2000 Grape Vines, comprising such varieties as Brighton, "the finest Red Grape vines, comprising such varieties as Brighton, "the finest Red Grape" for the West; Concord, "the popular market Grape;" Diamond, a very hardy Grape, a cross between Concord and Iona; Lindley, a Red Grape specially adapted for Colorado and Kansas; Martha (White Concord), Moore's Early, the best very early Grape; Salem, a coppery red Grape; and Worden, the best of the Concord seedlings, and probably the best black Grape in the United States.

One firm has undertaken for the various owners the planting of the above mentioned 1240 acres with 100,000 standard fruit trees, 165,000 Blackberries and Raspberries, and several thousand Grape Vines. The stock is all obtained from the old and reliable firm of Stark Bros., nurserymen, Louisiana, Missouri, about 1000 miles east of Denver, which

firm was established in 1835.

The special feature of the above fruit planting enterprises is that the 5 acre tracts are for sale on easy instalments extending over five years, the vendors caring for and cultivating the trees for five years without charge, and guaranteeing 90 per cent. of living trees at the end of that In this way the wear and tear and worry of the cultivation is all assumed and carried out by the vendors and paid for by them. Of course if a purchaser wishes to pay cash down he gets a discount. The land between the trees (which are planted 30 feet apart in rows 30 feet asunder) will grow large crops of Potatoes, Tomatoes, Hops, Cucumbers, Squash, Beans, Cabbage, Beets, Melons, Celery, Onions, and other vegetables, or can be used for poultry purposes.

At first sight it would appear that fruit growing near Denver is likely to be overdone but such is not the case inasmuch as the local

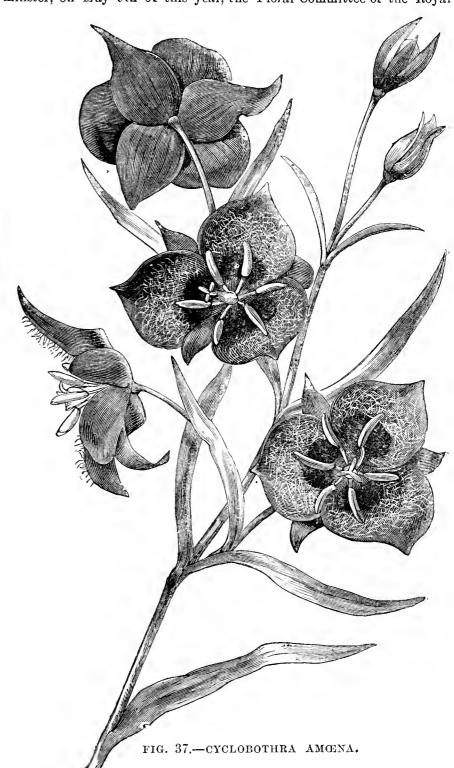

likely to be overdone, but such is not the case, inasmuch as the local market is unequalled, for the reason that less than 20 per cent. of the fruit consumed in Colorado is as yet grown in the State, the balance being shipped from California, Texas, Missouri, and other distant points, and sold at high prices. Denver, besides its own consumption of fresh

fruit and vegetables and the needs of the local canning factories, is the great distributing and supply point for a large area, including mining communities in the mountains at from 8000 to 11,000 feet altitude; and the fruit and vegetable grower and poultry farmer near Denver can load his produce into a waggon, drive into the city, sell for cash, and thus save the freight and middleman's profit, which he would have to pay were he further from the market.

Some of the prominent fruit and vegetable growers near Denver are Englishmen who have for years past practically demonstrated what can be done here, and at no distant date the vicinity of this city will become as famous for its orchards and fruit gardens as Kent, Devonshire, Hereford, or the Valc of Evesham.—Thomas Tonge, formerly of Manchester, England.

CYCLOBOTHRA AMŒNA.

THIS is an exceedingly pretty Cyclobothra, and when exhibited by H. J. Elwes, Esq., Colesbourne, Gloucestershire, at the Drill Hall, Westminster, on May 9th of this year, the Floral Committee of the Royal

Horticultural Society deemed it worthy of a first-class certificate. The flowers are of a pale rosy mauve shade, with three dark blotches in the centre of each. The sepals and petals are rather long and narrow, the latter being twisted, and they are hirsute. The anthers are white, which renders the flower more conspicuous. Fig. 37 represents Cyclobothra amœna.

THE WEM PEAS.

WEM, a quiet little town about twelve miles from Shrewsbury, is now fast becoming a familiar name with horticulturists, and has become celebrated as the scene of Mr. Eckford's present labours in the improvement of the Sweet Pea, and the culinary Pea also. Some 6 acres of land has been devoted to Peas at Wem, for the purpose of thoroughly testing his new varieties and securing a supply of seed to be grown in large

quantities in Essex, where several acres are also devoted to the culture of his Sweet Peas only, so great is the demand for seeds for home use and export to America and other parts of the world. The different varieties are sown thinly in rows in March, and when in full bloom they form a grand sight. Great care is taken that any plant not in its character should be allowed to remain mixed with the true variety. The rows are about 6 feet apart, so that an abundance of air is admitted, and there is plenty of space for a constant inspection of the plants, to detect any sport or "rogue."

Mr. Eckford is aiming at producing a yellow Sweet Pea, as well as a blue, and I think I may predict that this will be obtained some day, for in Primrose there is a shade of yellow, and this is being worked out further; and in Countess of Radnor and Emily Eckford we have a very near approach to a blue coloured Sweet Pea. The following new varieties not yet sent out will be welcome acquisitions to those fine sorts

already in cultivation:—

Duchess of York.—White, deeply striped and barred with pink; a

pleasing shade of colour, and a large flower of perfect form.

Duke of York.—The standard is bright rosy pink, with a primrose tint in it. The wings are primrose, tinted white, and it is a distinct, fine variety.

The Belle. -The standard is splashed with rosy pink, and the wings

with rose and blush. A charming variety, and will be a favourite.

Meteor.—Bright orange tinted pink, flushed with scarlet, and a violet tint which deepens to the centre. A bright, rich distinct variety

of great beauty.

Eliza Eckford.—The standard pink-tinted blush, with a rosy purple stripe, and splashed with pink towards the edges, varying in colour at times; the wings are creamy white. A very distinct and attractive variety.

Exectsion.—The standard is orange red, the wings a magenta red,

rich and bright in colour; flower large and stout.

Princess May.—White striped, and flaked with delicate pinkish

purple and fine.

Countess of Aberdeen.—White, delicately tinted towards the edge of the standard with soft pink, and with blush tinted wings; a charming

Mrs. Chamberlain.—White, striped, and flaked heavily with bright

rose; very striking and pretty.

Novelty.—Orange, tinted rose standard, and the wings of a delicate

mauve colour, lightly margined with rose, and very bright.

Blanche Burpec.—Wings and standard creamy white, large and stout in texture; a fine variety, named by Mr. Eckford in honour of an

American lady.

Of varieties already sent out, Mrs. Sankey is an unsurpassed white of the finest quality; Orange Prince is very distinct; Cardinal, brilliant scarlet crimson; Isa Eckford, The Queen, and Apple Blossom are all very pretty. Imperial Blue is a fine blue-tinted mauve, and Splendour is of the finest form and rich in colour. Lottie Eckford is as yet very little known, but is very distinct and handsome, resembling the old variety Butterfly, white, slightly margined with blue. Countess of Radnor, Her Majesty, and Dorothy Tennant are three superb varieties; and Mrs. Eckford, a delicate primrose tinted white, is a charming variety. Lemon Oueen is very distinct and Manarch Senator. variety. Lemon Queen is very distinct, and Monarch, Senator, Mrs. Gladstone, and Princess Victoria should be in every collection. Of the new varieties distributed this year, Firefly, Venus, Lady Penzance, and Blushing Beauty are all beautiful. Emily Eckford is extra fine, and very nearly a blue. Stanley is a very rich coloured, deep velvety maroon colour, and extra fine. Ovid is a flower of great beauty, truly a green and bright in selection. gem, and bright in colour. Royal Rose and Peach Blossom are two very pretty rosy pink-tinted flowers.

CULINARY PEAS.

The old Ne Plus Ultra has for a long time been Mr. Eckford's standard variety for breeding from for its excellent flavour and full blunt-ended pod, and trying to get very productive early varieties of much shorter habit with finer pods, but retaining all Ne Plus Ultra's good flavour. An inspection of the Wem seedlings through the growing season gives ample evidence of successful results, and many seedlings are discarded because not up to Mr. Eckford's high standard of excellence, and yet are very excellent Peas. These seedlings have to be grown for three or four years to get their true character firmly set by hard "rogueing" out of every plant not possessing the true characteristics of the variety, and then to be grown in sufficient quantity for sending out. A new variety named Aston Gem when sent out will be a great acquisition, and grows 3 feet high; a late blunt-ended pod; a wrinkled Marrow of Ne Plus Ultra breed, with long, large, handsome well-filled pods, and a heavy cropper from the root upwards. This is in every way a very fine Pea.

Critic. -This is a thin strawed Pea, the foliage not being so heavy as on many others, but it is a very fine market variety and for general use; blunt-ended pod; a midseason Pea, growing 5 feet high, coming into bearing quickly, and of first-class flavour.

[Colossus.—A profuse cropper; a second early wrinkled Marrow,

growing 5 feet high, and of first-class quality.

Wem.—A wonderfully fine variety with blunt ended pods, which are long and well filled, a Ne Plus Ultra seedling producing heavily from bottom to top and from 4 to 5 feet high.

Rex.—Bears a close resemblance to Wem, but has a deeper green pod, and is a first-class variety.

Epicure.—There were several long rows of this excellent Pea showing its free bearing qualities. It is a green wrinkled Marrow with large deep green pointed pods, with an average of ten peas in a pod, and of first-class quality. Height about 5 fect.

Juno.—A very dwarf-variety and most prolific. A fine late Marrow-

fat Pea.

Armorial.—This variety grows 4 to 5 feet high, has a very long blunt ended pod, with peas of a large size. A splendid exhibition Pea, as well as being first-class for general use.

Chieftain.—Long handsome slightly curved pods, with from ten to twelve peas in a pod, of dwarf habit and a profuse bearer, the plants having an abundance of pods from the bottom upwards, and the flavour

excellent.

Censor.--This variety was to have been sent out last spring, but the stock being limited it was withheld until next winter. It is a deep green wrinkled Marrow, growing 3 feet high, very fine pods, and a

valuable main-crop variety for productiveness and high quality.

Superabundant.—A dwarf Pea, an immense cropper of the first quality. A grand market variety, and bushy plants 2 feet and more

through of this kind showed up its productiveness.

Consummate. — Another high-class Pea, about 2½ feet high, with large pods, most productive, and of the best quality. Useful for market

gardens.

Other first-class varieties were to be seen, but enough has been said to show the kind of new Peas emanating from Wem. The seeds of culinary Peas are sown very thinly, and then the true character of each variety is seen, and heavy crops of well matured pods are secured. New Peas sent out by other raisers are grown at Wem for comparison in order to fairly test them. Mr. Eckford freely acknowledges merit in the productions of others, but I may safely say that by careful hybridising and judicious selection the Wem Peas will be only surpassed by others of very high class quality and superiority in other respects, and this will be no easy matter.—W. D.

EXPERIMENTS WITH SHANKING GRAPES.

FORTUNATELY I have not had much Grape shanking to contend with, but I have seen the evil and destruction it has caused in several instances, and my sympathy was very much with the growers who had charge of the Vines. Of all the ills to which Vines are subject I think shanking is the worst, with the exception of phylloxera. Each season up to a certain point the Vines may appear in the best of health, and all goes well until the unfortunate moment arrives and destruction of the crop sometimes follows in a very short space of time.

What produces shanking, and how can it be cured? I have heard some say the mischief proceeds from the roots being in a cold and unhappy state, others that sudden changes of temperature encourage it, and now the question arises, does thinning the bunches have anything

to do with it?

The first of these supposed causes I believe is the principal one, or this and the second combined; but I should certainly think the last has nothing whetever to do with the matter. I quite agree with the Editor's footnote on page 238, that Mr. Richardson may yet have Grapes free from shanking if he follows the treatment he has adopted with success so far if he thins the bunches. It would have been more interesting to readers, and I fancy a decided gain to the grower, had Mr. Richardson carried his experiments a little farther, and, coupled with the generous treatment to which the Vines previously were strangers, carefully thinned the bunches on every other Vine; he would have seen at a glance if the scissors had in any way assisted in the wholesale shanking, which I am inclined to doubt very much.

Mr. Richardson does not tell us which border he fcd, inside or out; and in wishing him every success with the work he has in hand, I cannot help thinking there may be another cause which may in a great measure account for less shanking this season than formerly—viz., the

tropical summer we have had.

I think it is pretty generally understood that anyone would experience considerable trouble in keeping a narrow inside border full of healthy feeding roots without constant attention to watering and feeding regularly and freely, which the Vines in question did not receive, especially so when the same Vines had unlimited root run outside. In fact, I should be a little surprised to find any roots in such a border under the conditions mentioned.

Now perhaps the excessive heat this summer has been such as to suit the roots in the outside border; at least, I should think they were in a happier state than in ordinary summers, or, in other words, has not these outside roots been too deep and too cold previously for the well doing of the Vines, hence the shanking? and has not the great heat coupled with generous treatment been the cause of bringing the roots nearer the surface with beneficial results?

In many localities where the subsoil is good and warm, Vine roots travel both a great depth and distance, and seem to revel in it; but I doubt if that would be the case at South Shields or the neighbourhood

by what I can remember of the locality.

I cannot believe that not thinning the bunches this season has assisted Mr. Richardson much in his improvement of the Grapes in his charge. If thinning assisted shanking in any way we should see a great deal more than we do, and thinning is sometimes done in a rough , and ready way.

A good bunch of Grapes can be easily spoilt with the scissors unless the operator knows what he is about, and no doubt much harm is often done by delaying the work too long, and if done clumsily or with blunt or rusty scissors each berry taken off leaves a wound, which does not

always stop at the footstalk. It would be interesting to hear how your correspondent succeeds next year, but my idea for the prevention of shanking is this—induce the roots near the surface or in an inside border, and keep them there by constant feeding winter and summer.—R. P., Impney.

ANYTHING that is written on the culture of Grapes is always interesting to old and young alike. Shanking of the fruit is a disease which causes much trouble, and in my opinion the problem is by no means solved. Shanking is not caused by one thing only, and Vines must be treated according to what is thought to be the cause of the disease, and it becomes the gardener in charge to put his head to work to find this out. Shanking of the footstalks first appears just as the berry is colouring, continuing to the time the Grapes are ripe. Some will shank even then, but these berries will be almost as sweet as the rest of the bunch.

Absence of calcareous matter in the border, and the roots in the cold subsoil, have been attributed as the causes of the evil; but overcropped starved rods which have not swelled according to their age with long spurs, obstructing the sap, over-richness of borders where they are new, bad ventilation while the Vines are in bloom, and hurrying them while

stoning, have something to do with it in several cases.

With regard to Mr. Richardson's case, he has done the right thing in lifting the roots, but I fail to see the advantage of not thinning the berries. If his rods have not swelled according to their age, he would obtain better fruit by running up young rods, not leaving too much length of rod the first year or two. He should feed the Vines well, fork the borders only once so as not to disturb the surface roots, and give a good coat of either stable or cow litter, letting it remain until the crop and laterals are ripe.—F. G.

I FAIL to see in what way the thinning of bunches of Grapes (when carefully done) should tend to the shanking of the retained berries as suggested by Mr. Thomas Richardson (page 238). Under the treatment so clearly described in the third and fourth paragraphs of Mr. Richardson's letter it is only reasonable to assume that had the number of bunches this year been reduced to seven or twelve on each Vine, according to its strength, and the berries thinned to about 1 inch apart, the result would be much more satisfactory than the magnificent (?) crop referred to by

your correspondent.

The improvement in the vigour and general condition of Mr. Richardson's Vines is not to be attributed to the fact of his having "dispensed altogether with the thinning scissors," but is traceable to the good resulting from the removal of the old worn out soil, and adding a more substantial and congenial admixture of "chopped turf, half-inch bones, and old lime rubble," and the subsequent top-dressings of cow manure, and applications of the "undiluted drainings of a cowshed." The fact is the Vines are now bearing evidence of the good they have derived from the change of fare. There is no reason why the Vines should not continue to yield good crops of creditable Grapes for several years to come. However, the Vines being very old I would suggest to Mr. Richardson the advisability of taking a young rod up, stopping the leading growths at 3 feet, and pinching out the laterals. In this way new rods may be secured in three or four years without interfering with the annual crop of Grapes, except by improving it, as the lower spurs may be cut clean away from the old Vines up as far as the shortened back young rods extend, these being allowed to bear a few bunches say two the first year four the second were six the third and bunches, say two the first year, four the second year, six the third, and eight or nine the fourth year, the old rods being then cut out at the fall of the leaf.

Means should also be taken to confine the roots of the Vines in a strip of border about 6 or 7 feet wide at the most, keeping them near the surface by top-dressing and liberal applications of liquid manure during the summer months to assist perfecting the crop. Where fermenting leaves to the thickness of about 2 feet can be put on the border when the house is closed for forcing without being considered objectionable, the gentle heat thereby imparted to the top-dressing will attract the roots to and keep them in the compost prepared for their special requirements and advantage. This is a simple and sure means of attaining an important end .- H. W. WARD, Longford Castle, Salisbury.

WITH the Editor's permission I should like to give my opinion on Mr. Richardson's experiments with shanking Grapes. The method he has found beneficial is quite the reverse of minc. Muscats I fancy would be better left unthinned under Mr. Richardson's treatment. I do not believe in cow manure in a raw state for Vines, the liquid no doubt will suit them to a certain extent. Has Mr. Richardson examined the drainage? That would be my first step. Lifting the roots near the surface by degrees has been successful with me. Take note of the soil, and water carefully, not twice a week, but once every two weeks would be quite enough in most cases. In an early vinery I have two Muscat Vines which my employer previous to my coming here a year ago was advised to chop down owing to shanking. I have given them part of the above treatment, and the result is a crop of excellent Grapes. I am in hopes of having better next year, after lifting the roots up to the front lights, as I only half lifted them last year, owing to it being late in the season when I took charge.

Did Mr. Richardson find any long tap roots when lifting? If not, I should advise him to look again, as I fancy there must be some straying into the clay under the lawn. Long thick fibreless roots straying

into a cold soil is, in my opinion, the principal cause of shanking. Get the roots near the surface, and top-dress with good turf, bones, charcoal, and lime rubble, then I think the Vines will require no cow manure, the liquid from it being quite sufficient.—WM. ROBERTS, The Gardens, Peniarth, Merioneth.

263

WITH the Editor, I agree that Mr. Richardson is on the way to have Grapes free from shanking on thinned bunches in the not far distant future. I do not believe that non-thinning of the berries will have much effect in preventing shanking, rather the reverse. It is obvious that the heavy feeding has exercised a most marked improvement on the Vines and their fruit, and if Mr. Richardson continues to feed with judgment I feel sure that no shanking will be the rule among his Grapes. At the same time I may perhaps advise caution in the use of cow manure applied several times in the season, in addition to undiluted drainings from the cowsheds every Tuesday and Friday. It may answer very well for a year or two, and then I think there is a danger of the Vine border becoming sour. To prevent sourness a soaking of lime water several times in the season would be advisable, and also prove beneficial to the Vines. Some of the various salts are also excellent if used with discretion, but soils vary so much in their constituents that only a practical knowledge of the elements therein can enable anyone to state what should and what should not be supplied. The question of manures and their action is somewhat perplexing, but I think a keen observer like Mr. Richardson will soon overcome all difficulties that may arise.— S. T. WRIGHT.

VEGETABLE CULTURE IN ADVERSE SEASONS.

(Continued from page 241.)

CAULIFLOWERS.

THE chief point to aim at in growing Cauliflowers for exhibition or home use is quick growth from beginning to end. If allowed to remain too long in the seed bed, or to be dry at the roots for a long period, clubbing will often follow, and this is vexatious. Very early heads may be obtained by sowing during August and wintering the plants in cold frames, or by sowing in heat in spring and transplanting to boxes or frames when in rough leaf, and when planted out put into shallow drills and protected by inverted flower pots or Fir branches. I prefer the last method of raising a stock for early use. There is not so much labour, anxiety, and risk of loss as in the case of autumn-raised plants.

Sow the early varieties in January or first week in February, and transplant the young seedlings in well prepared beds previously to putting them in their permanent quarters. Allow a good distance from plant to plant, according to the variety, and on the first appearance of clubbing earth up the stems, first treading the soil firmly round each plant. If the weather be dry and hot copious waterings will be necessary, and a good mulch should be applied. Sometimes in hot weather the fly is troublesome. The best remedy which I have found is anthracite coal ash dusted over the plants while they are damp with dew. Cut the heads when at their best. If allowed to remain long in very hot weather they soon become loose and discoloured and their chief attraction and quality lost. The varieties Early London, Walcheren, Magnum Bonum, and Eclipse, with Veitch's Autumn Giant for late use, I find sufficient for a large garden.

CARROTS.

Clean, even, and richly coloured Carrots are not to be obtained out of poor, stiff, and lumpy soil, especially if shallow. Deep cultivation should be the rule without exception for all root crops, and labour spent in this work will not be lost. Soil of a free and rather light nature is best suited for the production of clean, even Carrots. Where it is not so deal with it in early autumn; if wireworm be found apply a light sprinkling of soot and gas lime, and well incorporate with the soil as digging goes on. The ground ought to be broken up two spits deep, and if stable manure is used let it be decayed, without straw or litter of any kind, but not dried. Well break up the bottom spit of soil and leave it in position, turn over the top spit and leave the surface rough, then a good seed bed will be easily made in the spring. A rough surface admits air to the soil below, sweetening it. Some persons have great faith in chemical manures. Most of these, if good and properly used, are no doubt beneficial. They may be sprinkled on the surface of the bed early in the spring while the soil is dry and incorporated in it with a fork, at the same time breaking up all lumps of earth. After a time, when it is desirable to sow, make the remaining ground smooth, and draw drills a foot to 15 inches apart. Sow the seed thinly, scattering a little burnt earth and wood ashes in the drills before closing them with the rake. The preparation of the ground for Carrots will answer well for Parsnips and Beetroot.

Thinning is the next important operation, and should be done at an early stage of the plant's growth. It may seem a trifling affair, but it requires to be carefully carried out, and 4 to 6 inches or more should be allowed for the plants to develop properly. Draw the weakest first, then in a few days complete the thinning, always observing that the plants left be isolated, so that in taking away those not wanted its roots are but little disturbed. If it is one of a bunch the chances are that deformity in the root will result, though at the time of thinning it would not be observable.

The bulk of these remarks apply with equal force to the cultivation of the Turnip and the Onion, only these crops require firm ground. Rolling the ground does not compress it sufficiently, and I rather prefer treading. It is a little more tedious perhaps, but results justify the practice. Rake over the bed after sowing, but do not tread or roll it, as if that is done, and rain follows, the surface cracks in drying, and the seedlings do not grow freely. In very hot weather spread a herring net over the ground after sowing the Turnips, and leave it on till the rough leaf appears. The fly rarely troubles while the net is on, however hot the weather may be; afterwards use the anthracite coal ashes to prevent its ravages.

Mildew is very destructive among Onions. On its first appearance rub flowers of sulphur on the affected parts. It generally attacks the Onions during the month of August, and will work much damage among them if not quickly checked. At first it is not observable, ordinarily, but upon close inspection small patches of grey dust-like powder will be found on the stalks, and these if left untouched will soon cause the stem to turn yellow and decay. This premature loss of foliage is detrimental to the sound keeping of the bulbs during winter. If extra large Onions are desired the plants should be raised in January, and grown thinly in boxes before being finally planted out in April, and the crop treated generously throughout.

Good varieties of Carrots are Early Gem for early use, and New Red Intermediate for the main crop. Beetroot, Pragnell's Exhibition, Blood Red, and Carter's Perfection. Parsnips, Student and Hollow Crown. Turnips, Jersey Lily, Snowball, and Golden Rose. Onions, for autumn sowing, White Leviathan; for spring sowing, Rousham Park Hero, Improved Reading, James' Keeping, and Ailsa Craig.—G. GARNER.

(To be continued.)

NOTES BY THE WAY.

An oblique line to the left of the main road from East Grinstead, near which are Oakleigh, Brockhurst, and Brambletye, leads in the direction of Hammerwood, the residence of Oswald Smith, Esq. exact direction of the line is more than I was able to grasp, for an obliging guide led me by winding footpaths and zigzag approaches, beguiling the long and weary way by frequent references to a mysterious "short cut" which was to be found sooner or later. Hearing about short routes when it is only too evident that you are taking a long one is about as consoling as a landlady's assurance to a hungry traveller that she would have had a splendid dinner ready for him if disappointments with tradesmen had not left her with nothing but bread and cheese. Not being found on the outward journey, the guide decided that we must return by it. He had forgotten Mrs. Glasse's preliminary point in the recipe for jugged hare, which was to catch it first. The only "short cut" discovered was one which led through a farmyard, wherein a large, gaunt, and hungry looking dog was dragging round several feet of broken chain, and the settled conviction that we were at last on the straight road which had taken possession of the guide's mind deserted him with startling suddenness. But we found Hammerwood and got back from it, so I take it that a veil may be drawn over the doubts and difficulties engendered by seeking for a path that either does not exist or is too well guarded for use.

Mr. Oswald Smith is, I believe, either a brother or near relative of Mr. Martin Smith, but certainly he does not seem to share the fraternal enthusiasm for Carnations. I do not know that there is anything very striking in this fact, for as yet no gardening Ibsen has arisen to show us that heredity has its say in floral tastes, and we can do very well without him. But Mr. Martin Smith is such an enthusiast, and so convincing in his championship of the great summer flower, that there is room for a mild species of wonder that Hammerwood has not its quota of white grounds, yellow grounds, selfs, and the rest of the Carnation string.

"A person of the name of 'Arris," as Mrs. Gamp would have said, has charge of the gardens at Hammerwood. He is a broad, deep chested, hale and hearty looking gardener, and has earned quite a reputation in the locality as a vegetable grower. Perhaps the fact of his pleasant house opening direct on to the kitchen garden may have something to do with this, although it is not easy to trace any distinct connection between the two facts. It may be that as the vegetable quarters are also the pleasure grounds, so far as his residence is concerned, he takes a special pride in having them well filled, and this view I should be the last to traverse, apart altogether from fear of a cudgelling from our critical friend "A. D." to whom, as we all know, no Rose or Carnation has the beautiful points of an Onion or a Potato. Be the reason what it may, it is the exception to meet with a kitchen garden so well stocked and so admirably kept as that at Hammerwood. It is full of good produce, clean and orderly. Without being hypercritical, it may be advanced that many kitchen gardens would be improved if the "place-for-everything-and-everything-in-its-place" rule were observed in them as carefully as it is in this well-managed Sussex garden.

Hammerwood may be said to be the centre of a little kingdom of which Mr. Smith is the reigning monarch. It is far away from a town or even village, being snugged away amongst the fields and woods. But the beneficent potentate has built a number of excellent dwellings for his workpeople, a fine school and a handsome church. The little hamlet and the neighbouring mansion which fosters it lie calm, peaceful, and secluded, typical of many a pastoral picture in Merrie England. The hum of busy life, the ceaseless tramp of the "madding crowd," do not penetrate there. There is a restfulness and repose about the place which

are full of charm. The residence is embowered in lofty trees and huge masses of Rhododendrons. There are some immense banks of the old caucasicum quite close to the flower garden adjoining the house which must present noble effects when in full bloom, despite the modest beauty of the variety as compared with some of the gorgeous hybrids. I could not help thinking, indeed, that the semi-wild and natural aspect of the grounds was much in keeping with the surroundings, and perhaps felt inclined to accuse Mr. Harris of a leaning to vandalism when he talked about clearing some of them away; but superior varieties are, I understand, to take their place.

The sight of these wonderful bushes suggested the reflection that Sussex must possess a record hard to beat in her examples of this fine old Rhododendron. I remember dropping unexpectedly upon a huge tree—for it was nothing less—in a garden at Groombridge a few years ago, not very far from the foot of the famous hill. It was on a sunny afternoon late in spring, and the gigantic bush was laden with blossom. I am unable to recall my estimate of its size, but it was larger than many a cottage. Beyond Crawley, too, far past Cheal's, through the old town, up the hill and so on along the Brighton road, attention is attracted by some very fine bushes on the left, which when carrying their spring burden of flowers are a sight to linger in the recollection even when the manifold attractions of ancient Brighthelmstone are exercising their influences. This, however, is a digression.

A charitable and considerate pen must be wielded in touching on flower gardens this year. Gardeners waited anxiously for the fulfilment of Falb's weather predictions, and the filling up of their beds consequent on the rains which he generously provided, but alas! the professorial vaticinations proved to be a delusion and a snare. It is not the fault of Mr. Harris and his suffering brethren in other parts if the beds were only half furnished when they ought to have been amply filled. The designs were right enough, and so was the material to begin with, but the plants would not grow as they should have done, all their time being taken up in keeping alive under the fierce and protracted heat. Not that the bedding was bad, quite the reverse. There were some attractive arrangements, and quite a brave glow of colour in some cases, but there as elsewhere thin beds were the rule.

It will not be in the least surprising if there should be a check in the triumphant march of Tuberous Begonias, as a result of this season's experiences. Their most partial admirer must admit that the season has been somewhat too much for them in a great many places. They have not shone radiant as of yore, luxuriant in leafage and brilliant with flowers, but have been pinched, starved, and melancholy. It is easy to tell when plants are unhappy, and dejection has been written large on most of the bedding Begonias which I have seen in this season of sultry memory. But in venturing (spite of the colossal failure of the luckless professor) on this little prophecy it is not my wish to suggest that the Begonias merit the rebuff which fate perhaps has in store for them. That would be unjust. All I wish to do is to point out the probable result of their failure this year. It must be remembered that thousands of people act mainly on impulses, and the first thing that they will do in observing the poor condition of the plants will be to decide on doing without them another year, forgetful that we have had a season in a hundred, and that the Begonias have not had a ghost of a chance of doing themselves justice. 'Twas ever thus. Praise and admiration in the hour of success, disparagement and distaste in the moment of failure. But the flowers will win after all.

Speaking of Begonias reminds me that I ought to say how exceedingly well Mr. Harris grows them in pots, for he has a very fine display. Another useful decorative plant that he grows extremely well is the Cockscomb. He had a very fine specimen of Veitch's Dwarf, which, as grown at Hammerwood, is distinctly superior to the Glasgow Prize of my novitiate days, for, although very dwarf, the combs are even and finely developed. Orchids are well grown at Hammerwood, and so are many other plants under glass, such as Clerodendrons, Bougainvilleas, Bouvardias, Acalyphas, and others, but I have not space to enumerate them all.

Fruit comes in the same stream of praise, especially Peaches and Nectarines. The early house is a very wide and roomy structure, and contains some very large trees of Dr. Hogg, Princess of Wales, and Stanwick Elruge. Trees of the latter which were bought a few inches high in small pots of Mr. Rivers twelve years ago now have a spread of 20 feet and bear enormous crops. I was about to omit mention of Mr. Harris's Melon. What would he think of me if I did? I did not leave Hammerwood without tasting it, and I must not quit it now without saying a word about the fruit. Please do not understand me to suggest that there is anything astonishing in a gardener having a Melon of his own raising. Almost every gardener has one. It is a peculiarity of the craft to get a hybrid which puts every other Melon into the shade, and which is so precious that a slice has to be cut for you with great care lest you should carry away a seed in your mouth, sow it, and basely sell the stock thus procured for a fabulous sum. The Grinstead gardeners have this amiable little weakness strongly developed. Each runs a Melon of his own. The neighbourhood is positively overflowing with wonderful varieties. Each, of course, is a great deal better than the other; and the other, equally as a matter of course, is better than each. This may seem peculiar, but, as a proof of its accuracy, I may mention

that I had the information from the raiser in every case. Mr. Harris's is really a very good Melon, being an even, well-netted, handsome, orange fleshed fruit of very excellent flavour. I have not tasted a better one this year, and very few anything like so good. He calls it No. 1. In a season of poorly flavoured Melons it is a pleasure to come across a variety that possesses really high quality.—W. P. W.

EVENTS OF THE WEEK.—As notified in another paragraph, the Committees of the Royal Horticultural Society will meet at the Drill Hall, Westminster, on Tuesday, September 26th. On Wednesday, the 27th inst., a Show of hardy fruit will be opened at the Gardening and Forestry Exhibition, Earl's Court, and will continue the two following days. The County of Gloucester Show will also take place on the 27th and 28th.

— THE WEATHER IN LONDON.—During the past week fine weather has for the most part prevailed in the metropolis, although several local showers have occurred. Sunday opened fine, but gusty, and Monday proved cloudy with appearance of rain. On Tuesday last a few showers fell, and Wednesday morning was dull. At the time of going to press, however, it is fine, and rain is much wanted.

—— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY. —The seventh annual dinner of this Society will take place on Tuesday, October 10th, at 6 P.M., at the Cannon Street Hotel, E.C., on which occasion P. C. M. Veitch, Esq., of Exeter, has kindly consented to preside. Tickets, 5s. each, can be obtained from Mr. W. Collins, Secretary, 9, Martindale Road, Balham, S.W.

— ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will take place at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, September 26th, when prizes are offered for Gladioli. At three o'clock Mr. W. Iggulden of Marston Gardens, Frome, will deliver a lecture on the "Causes of Failure in Eucharis Culture."

- DEATH OF MR. HUGH LOW. - With great regret we record the death of Mr. Hugh Low, of the well known firm of nurserymen at Clapton, which took place suddenly on Sunday, September 17th, at his residence at Upper Clapton. The deceased gentleman was thirty-two years of age, and his untimely death will be regretted by a wide circle of friends; he leaves a widow and two little girls. For some time past Mr. Low had been in indifferent health and returned from a visit to Cromer last week, but was not taken seriously ill until Saturday, after which pneumonia developed rapidly with unfortunate fatal results. Mr. Low was in partnership under the style of Messrs. Hugh Low and Co., with his two younger brothers, by whom, we understand, the business will be carried on. He was a member of the Committee of the Royal Gardeners' Orphan Fund, and a most estimable man. The funeral took place at 12.30 P.M. yesterday (Wednesday) at Abney Park Cemetery, Stoke Newington, and the ceremony was attended by many sympathising friends.

- DESTROYING WEEDS.—On seeing a paragraph on this subject in the last number (page 245) from "Meehan's Monthly," I was reminded of a conversation I recently had with a gardener on the eradication of the small Bindweed, whose roots go down, as is well known, to an incredible depth. The pest appeared to have quite vanished from a formerly infested patch, and I asked how he managed it. "Oh! an old gardener told me the secret. He said you must hoe them every Wednesday. I did, and they are quite done for." It was good; and I should like to have known that old gardener, who evidently knew as much of human as of weed nature. It is pretty clear that if he had said "every week" they would have been hoed, once on a Monday perhaps, and then on the Saturday week, and so on, and the whole thing would have fallen through sooner or later; but by naming his day he gave a useful little touch of a superstitious charm for an ignorant man, and also made sure that it would be done every week. Let those of my friends who are troubled with Bindweed, Coltsfoot. and Dandelions, try the "every Wednesday" plan for them, and report if it does not answer.-W. R. RAILLEM.

— THERE are in the United States thirty-two botanical stations. Systematic botany and the physiology of plants are studied more or less at all these stations, and at every one of them particular attention is given to the maladies of plants and the disease causing fungi.

—— LILIUM JAPONICUM VAR. ALEXANDRÆ.—We observe in the catalogue of Messrs. Wallace & Co., Colchester, that our illustration of this new Lilium on page 57, July 20th, has been copied without permission and published without acknowledgement. This is not in accordance with the canons of literary propriety. Moreover, the flower that our artist sketched, and which is accurately represented in the Colchester catalogue, was not grown by Messrs. Wallace & Co., but by Messrs. Veitch & Sons, Chelsea.

—— Grapes for Wine.—In some parts of Médoc the vintage began as soon as the 20th of last month. Such an early date has not been known for generations, the usual period being the first half of September, sometimes even the last days of the month. The Girondins all agree in saying that the crop this year will be a splendid one in spite of drought. It is necessary to say "will be," for most of the growers have had to suspend the gathering of the Grapes for want of casks, which are so scarce that they fetch unusually high prices.

— Suburban Sparrows.—I should like to confirm all "Davies Duffryn" (page 214) alleges against these mischievous depredators, although he omits from his indictment one of their worst vices—viz., pecking, and thereby destroying all ripe or unripe fruit. But the difficulty is how to get rid of the pests. Cats seem quite useless, and hawks cannot be sufficiently tamed, I fear. Shooting is out of the question in a garden; consequently any inventor who devises a simple and inexpensive sparrow trap would very quickly make his fortune.—Country Amateur.

PERENNIALS IN TOWN GARDENS.—A very good word for perennials as becoming and profitable inhabitants of town gardens was spoken by Mr. Walter Child, F.R.H.S., in a paper delivered before the Birmingham Amateur Gardeners' Association the other day. Mr. Child is a very successful exhibitor of these plants, and has contributed substantially to rescue many worthy perennials by a sedulous selection of the best varieties, and by the most suitable cultivation. For a long period many of these old-fashioned garden flowers have enjoyed the loyal regard of those to whom gardening is a pleasure.

— Gardening Appointments.—Mr. William Carr has resigned the post of head gardener to Viscount Hill, Hawkstone, near Shrewsbury, in order to fill a similar position at Yeaton-Pevevey, the seat of Sir Offley Wakeman, Bart., Shrewsbury. Mr. Carr was foreman at Hawkstone under the late Mr. William Pratt, whose successor he became in the management of the gardens there when that good all-round horticulturist left ten and a half years ago to become head gardener to the Marquis of Bath, at Longleat. Mr. James Fawkes, for the past two and a half years gardener to the Hon. Mrs. Douglas Pennant, Lillingstone House, Buckingham, and previously foreman with Mr. Hope, Middleton Park Gardens, Bicester, has been appointed gardener to the Earl of Jersey, Osterley Park, Isleworth, Middlesex.

- THE NEW ZEALAND KARMAHI TREE.-A correspondent writes:--"So great has been the demand for Wattle bark that this valuable Australian tree is become scarce. But there is a native tree which I think might be found no mean rival of the Australian Wattle. I refer to the Karmahi, or Kamai, as it is generally called. This tree is known to botanists as Wienmannia, and is often called by bushmen "Bastard Birch." There are two varieties of the tree. One found in the North Island and northern portion of South Island, and the other peculiar to southern forests. In the great Tautuku Forest, extending from the Clutha to the Mataura, the Kamai is one of the most abundant trees. It grows to a height of 30 feet to 40 feet, and often attains a diameter of 20 inches to 30 inches. It is covered with a tolerably thick bark, which contains a considerable amount of tannic acid and dye material. The Maoris use the bark to dye flax, and produce a fast black or dark brown colour. They bruise the bark and boil it along with the flax to be dyed, which is afterwards steeped in swamp mud, where the iron held in solution comes in contact with the tanning of the bark, and so fixes a black dye. Experiment is all that is wanted, I feel sure, to bring the Kamai bark into general use, both at the tannery and at the dyeworks. From a series of chemical experiments made myself a few years ago on the barks of our forest trees, I proved the Kamai to be one of the richest in tanning material."

- MR. GEORGE GALLAHER, late gardener at Kilkewan House Ayrshire, informs us that he is about to commence business as florist and fruit grower at Burnhead, Liberton, Edinburgh.
- DESTROYING WASPS' NESTS.—It is reported that Mr. Whitbread, M.P., has caused the destruction of no less than 800 wasps' nests in his park at Southill. A few weeks ago Mr. Whitbread offered 6d. for each wasp's nest destroyed in his park, with the result that he has just paid on this account over £20.
- —— A POTATO PROBLEM.—On raising Potatoes in several gardens near Tenbury many of the tubers are found to be quite flabby, as if scalded or frosted, though some of them are only affected at one end. Have other readers of the *Journal of Horticulture* experienced anything of the kind? I shall be glad if the cause can be explained, and if the tubers will be good for seed. They go black on being cooked.—MIDDLEDALE.
- A WHITE FLOWERED COBŒA SCANDENS. When potting some seedling Cobœa scandens in the spring I noticed one much lighter than the others in the foliage and stems. It was marked and turns out to be a white flowered variety. Can you tell me if this is unusual, as I have never seen a white one before?—H. R. RICHARDS. [Light coloured forms are not uncommon, but so far as we know a pure white one has not been exhibited. Have you any flowers to send for examination?]
- —— QUEEN WASPS.—No delay should take place in destroying every nest known to exist, as the queens for another season's plague are very numerous in the nests now. I pointed out last autumn how necessary it was to hunt up all the nests, as they were producing an unusual number of young queens, and the season from the first has been highly favourable for their development. Some seasons I have had difficulty in finding a queen being developed for another year, which is to me unaccountable, and a few years ago this occurred to such an extent that to see a wasp the following summer was a rarity.—

 J. HIAM.
- CALIFORNIA MIDWINTER INTERNATIONAL EXPOSITION.— The Agricultural and Horticultural Hall of the Exhibition to be held in San Francisco during the winter of 1893-94 has an area of 300 by 125 feet. Agricultural products, horticultural products, floricultural products, forest products, specimens, botanical, fossil and mineral, samples of cereals and grasses, when not intended to be returned, may be carried from Chicago and Common Points west thereof to San Francisco at one-half the regular tariff rate for same. The general rules and regulations and information for intending exhibitors are now ready, and may be obtained by applying to the Department of Publicity and Promotion, California Midwinter International Exposition, Mills Building, San Francisco, Cal., U.S.A.
- A MELON NOVELTY.—The remarks of a correspondent on page 218 of the Journal induce me to relate a similar experience with Sutton's Triumph Melon, a variety with a thin skin and deep scarlet flesh. When the fruit was cut it was found that fully half the seeds had germinated, many of the plants having roots 2 inches long, and what surprised us still more the seed leaves were quite green. Acting upon instructions I placed a few of the seedlings in small pots on July 24th, and a fortnight later transferred them to 6-inch pots. From the first they made healthy growth, in fact there is no difference between them and others raised in the usual way. We planted four plants in the Cucumber house on the 21st of August; these are now flowering, but I fear the season is too far advanced for us to be able to ripen a crop of fruit upon them.—P. TARRY, The Gardens, Holly Hill, Hartfield.
- Tunbridge Wells:—"As an illustration of the shifts to which birds have been driven for food by 'the unexampled drought,' I may mention that within the last ten days the blackbirds have attacked and devoured dozens of some fine Black Hamburgh Grapes growing in my 'curate's vinery.' Have any of your numerous readers suffered in the same way? All the scarlet heps on the Cockspur Thorns were cleared off last month, and this morning (Sept. 16th) I saw five of my sable friends making a square meal off the heps on a White Thorn, intending, no doubt, to lay my Grapes under contribution for dessert. What these beautiful birds are to do for food in the coming winter, if it be a hard one, is not easy to say. Those who enjoy their presence and song in spring and summer must be careful to feed them well through the winter. Minced uncooked beef will be better for them than Black Hamburgh Grapes."

- WIDCOMBE HORTICULTURAL CLUB.—There was a large attendance at the meeting of the Widcombe Horticultural Club held on September 12th, when the Rev. E. Lascelles, Rector of Newton St. Loe, read a paper on "Begonias," flowers he has cultivated with so much success for several years. Mr. W. Pumphrey, the President, occupied the chair. Mr. Lascelles dealt with his subject in an interesting and able manner.
- THE SUNFLOWER.—Among neglected crops the Sunflower is one of the most interesting. Few people who grow it for ornament have any idea of its usefulness. A daily contemporary asserts that birds of nearly all kinds thrive on the seeds, and there is no more fattening food for poultry. Cattle like them, too, either in their natural state or crushed and made into cake; while the very stalks may be ground up and mixed advantageously with other fodder. In one or two places in Scotland a few acres have been devoted to Sunflower cultivation for the past few years with very satisfactory results.
- —— COVENT GARDEN FRUIT.—With a view to putting beyond doubt the little likelihood of spreading cholera through the medium of Covent Garden, as some questions in the House of Commons might lead the public to believe, a reporter pursued inquiries on the subject. The Market Inspector told him:—"There has been no dangerous fruit or anything approaching to it within the market area. It does not pay to send consignments of bad fruit. If it were otherwise buying would stop, and the wide reputation of the market would be ruined. We have the best name in the world for sound fruit and vegetables, and it is a poor market indeed for bad stuff."
- VARIEGATED ALOES.—It not infrequently happens that visiting some comparatively remote and almost unknown garden one meets with something of more than usual interest, and I found that to be so recently in Somersetshire, for when at Inwood House, Mr. Wilkins kindly drove me over to Milborne Port to see Mr. Bowers and the quaint old gardens attached to Venn Hall, the residence of Sir A. Medlycott, and there I found, standing on a terrace, a number of huge variegated Agaves, some of the finest and cleanest I have ever seen. They seemed specially to be fitting in this fine old garden. In one of the houses there is a gigantic Adiantum farleyense some 7 feet through. It is in a large pot, and growing in a shaded position. Many other good plants show that the cultivation in the highest perfection of this grand Fern is well understood here.—A. D.
- FERN HOUSES AND FERNERIES.—A block of formal houses, close to the mansion at Inwood, is now full of Ferns, in pots and standing on shelves and stages. Of course the result is, as is invariably the case in similar Fern houses, much uninteresting flatness and formality. Lady Theodora Guest, the munificent owner of this fine property, has resolved to convert these formal houses into one artistic fernery, and to that end the entire contents will be removed, the stages and shelves cleared away, the floors covered with substantial rockwork (which Mr. Wilkins will construct), good roomy alleys provided, and then the whole [planted artistically, so as to produce a very delightful effect, that can be at all seasons enjoyed. Then a Fern house becomes a real fernery. At present the houses are most unattractive to ladies; then they will be a favourite place of resort.—A. D.
- --- A GENERAL HORTICULTURAL SOCIETY.—We learn from the "Garden and Forest" that the birth of a General Horticultural Society took place on August 25th, immediately after the Horticultural Congress at Chicago, in Mr. Samuel's office. The scheme provides for three officers at large, a president, vice-president, and secretary-treasurer. Each country is entitled to a vice-president and secretary-treasurer. The three general officers, together with the secretary-treasurer of the country in which the president resides, constitute a committee on byelaws and on finance, while all the officers constitute an executive committee. The object of a general Horticultural Society is the promotion of correspondence, the exchange of plants, seeds, books, and other articles, and the general extension of fellowship among the horticulturists of the world. The membership of the society consists of horticultural societies and of individuals, who pay an initial fee of two dollars and a subsequent annual fee of one dollar. Only three general officers are yet determined. These are-T. J. Berckmans, Georgia, president; Henri L. de Vilmorin, Paris, first vice-president; and George Nicholson, curator of the Royal Gardens, Kew, England, secretarytreasurer. It is expected that one-third of all the money collected in each country is to be retained in that country for the expenses of its own branch of the work, the remainder going into the hands of the secretary-treasurer.

RAMSGATE PUBLIC PARK.—In the most beautiful weather a ceremony in connection with the Ramsgate Public Park took place recently. As far back as September 29th of last year a somewhat similar ceremony occurred, marking the transfer of the property from the trustees of the former owner to the representatives of the ratepayers. The present occasion, however, simply marked the close of the operations of beautifying and laying out the grounds, operations carried out most efficiently by Messrs. Cheal & Sons of Crawley, Sussex. Among the main features of the Park the finest piece of constructive work is the handsomely designed Doulton-ware terrace, 246 feet in length, 25 feet wide at the narrowest, and 75 feet at the widest part.

THE BOTANY OF TIBET.—A recent issue of the "Chemist and Druggist" remarked that Dr. Thorold, who, in 1890-91 accompanied Captain Bower's expedition through Tibet as a scientist, collected specimens of all the plants he saw during his journey across the country from west to east. The collection contains only 115 species, all told, showing the poverty of the Tibetan flora in the district traversed; a poverty which, however, is not astonishing considering that the greater part of the route lay over a country as high above sea-level as is the top of Mont Blane. The 115 species belonged to no fewer than twenty-eight natural orders, and only about half a dozen species were quite unknown at Kew. One flowering plant was collected at an altitude of 19,000 feet—probably the highest point on record in the history of botany.

LIQUORICE.—The inhabitants of Elizabethpol and Baku in the Caucasus derive considerable benefit from Liquorice (Glycyrrhiza glabra), which grows wild, needs no cultivation, and multiplies spontaneously. In 1878 two Greeks turned their attention to the large quantities of Liquorice in Caucasia; in 1886 they erected a large factory for drying and pressing the Liquorice, which they annually exported to America. The remunerative trade soon attracted others, and to-day there exist four prominent commercial houses which carry on a wholesale trade in Liquorice, and two of which have erected extract factories in this country. Annually there are produced about 108,339,000 pounds of raw Liquorice, which, after drying, yields 36,113,000 pounds of marketable merchandise. For raw Liquorice the factories pay on the average fivepence halfpenny per 100 pounds.

RECLAIMED LAND IN HOLLAND.—In the year 1886 a society was organised in Holland to make plans for the draining of the Zuyder Zee. It now officially reports that three-fourths of the soil covered by these 900,000 acres of water is as fertile as surrounding districts, and proposes a scheme of drainage which will leave 300,000 acres in the centre as a lake, while the rest will be redeemed at a rate that will annually render from 12,000 to 15,000 acres habitable. According to the "Garden and Forest" the cost of the entire work is estimated at £15,250,000. The largest enterprise of the same sort hitherto earried out has been the draining of the Haarlem Lake, which, after thirty-nine months of labour, added 46,000 acres to the solid soil of Holland. When the Zuyder Zee was formed by an inundation, in the thirteenth century, some 80,000 lives are believed to have been lost.

- THE WASP PLAGUE.-Mr. J. Lloyd Bozward, Worcester, writes to the last issue of "Nature" as follows: - "Of late much has been written about the seasonal prevalence of wasps, and the mischief, in several places, wrought by them. May not, however, their use in keeping down many forms of insect pests be set off as some sort of palliative? Wasps are exterminators of aphides, and although the season has been favourable to insect life, next to no damage has been done to the Hop bines or the corn or pulse crops of Worcestershire or Herefordshire by these latter pests-frequent destroyers of crops. Is it suggestible that the excessive wasp prevalence is attributable in some measure to the abundance of their insect prey, just as has recently happened in Seotland, in the instance of the multiplication of the short-eared or 'woodcock' owl, owing to the plague of field voles? The owl is a winter immigrant, usually leaving in spring. 'Nests in ordinary seasons are of rare occurrence in Great Britain, but owing to the vast increase of their favourite food-the field vole-these owls have not only arrived in increased numbers, but have remained and bred in Seotland all over the affected districts, laying from eight to thirteen eggs, and rearing large broods,' instead of the few eggs these owls have hitherto been accredited with laying. I am a fruit grower. Much damage has this year been done to the fruit; not, however, by the wasp tribe, but by hungry birds, the fruit having even been attacked in an unripe state. According to my experience wasps do not become household pests till the falling off of insect prey towards autumn."

—— SPIRITS FROM MULBERRIES.—The production of spirits from Mulberries, Pears, Cherries, and other fruits depends upon the yearly result of the vintage, as the producers seek to repair the eventual loss in wine and wine-spirits by substituting the above-named fruits. The production from fruits grown in the Caucasus during the last five years averaged about 65,000 vedros (211,185,000 gallons) of Mulberry spirits free from water. The other fruits are used for this purpose only in inconsiderable quantities.

— FRUIT CULTURE IN NEW ZEALAND.—The latest papers from Auckland, New Zealand, describe the cultivation of the Orange on the peninsula to the north of that town as taking a marked development, and superseding the cultivation of the Apple and stone fruits. It is not generally known in England that this northern portion of New Zealand, whilst being as green and well watered as Devonshire, can grow all the fruits of Sicily and Devonshire combined. The Lemon, the Seville Orange, the Loquat, together with Peaches, Nectarines, Apricots, and Apples, flourish exceedingly in every garden about Auckland; but the Sweet Orange requires the rather higher temperature some seventy miles to the north to bring it to perfection. Slowly the people are becoming aware of the unbounded possibilities of fruit growing awaiting them in the future, and it merely requires accessibility to a large market to convert this part of New Zealand into a paradise for small fruit farmers.

- BEGONIAS AT HENBURY HILL.-Mr. W. Strugnell writes:-For some years past the gardens at Henbury Hill have acquired a local fame in respect to Tuberous Begonias, which are well and extensively grown both indoors and in the open air. I made a call recently, and I was agreeably surprised to find such a wealth of bloom and variety after such a prolonged period of drought. Two large semi-circular beds are filled with Begonias and subtropical plants, having a background of tall evergreen shrubs. This shows up the Begonias in splendid contrast to the sombre tints of the evergreens, and being in direct view of the house must give an immense amount of satisfaction to their owner, A. E. George, Esq., during the summer. The site now occupied with the Begonias was once a portion of the line of shrubs extended forward by Mr. Smith to suit the object under notice, and being well trenched and manured each year, the plants grow with unusual vigour. The greenhouse and subtropical plants used include Ricinus Gibsoni, R. communis, Grevillea robusta, tall Acacias, Wigandias, Fuchsias, Brugmansias, and Cannas in variety. These grow well, and are interesting almost to the same extent as the Begonias. Mr. Smith devises a fresh plan for each year, but as this has been carried on several years the difficulty now is to find something original. Begonias embrace many colours and intermediary shades, and a course of crossing and intercrossing produces a strain of marked excellence both in habit of plant, size, and shape of blooms. Some of the flowers are massive and erect, others drooping and of medium size, but all are good. None but singles are grown, double flowers finding no favour at Henbury Hill. The plants are raised from home-saved seeds each year.

- SENDING FRUIT TO COVENT GARDEN 180 YEARS AGO .-A correspondent sends us the following extract from the "Spectator" of 1712. The writer appears to have been taking a holiday in August. He says:—"I lay one night last week at Richmond, and being restless, not out of dissatisfaction, but a certain busy inclination one sometimes has, I rose at four in the morning, and took boat for London, with a resolution to rove by boat and coach for the next four-and-twenty hours. When we first put off from shore we soon fell in with a fleet of gardeners bound for the several market ports of London; and it was the most pleasing scenc imaginable to see the cheerfulness with which those industrious people ply'd their way to a certain sale of their goods. The banks on each side are as well peopled, and beautified with as agreeable plantations as any spot on the earth; but the Thames itself, loaded with the product of each shore, added very much to the landskip. It was very easy to observe by their sailing, and the countenances of the ruddy virgins, who were supercargoes, the parts of the town to which they were bound. There was an air in the purveyors for Covent Garden, who frequently converse with morning rakes, very unlike the seemly sobriety of those bound for Stocks' market. Nothing remarkable happened in our voyage; but I landed with ten-sail of Apricoc boats at Strand Bridge, after having put in at Nine Elms, and taken in Melons, consigned by Mr. Cuffe of that place, to Sarah Sewell & Company, at their stall in Covent Garden. We arrived at Strand Bridge at six of the clock, and were unloading when the hackney coachmen of the foregoing night took their leave of each other at the Dark House to go to bed before the day was too

far spent. Chimney-sweepers passed by us as we made up to the market, and some rallery happened between one of the fruit-wenches and those black men about the devil and Eve, with allusion to their several professions. I could not believe any place more entertaining than Covent Garden, where I strolled from one fruit shop to another, with crowds of agreeable young women around me, who were purchasing fruit for their respective families. It was almost eight of the clock before I could leave that variety of objects." [We think it would be difficult to find Apricots grown on the banks of the Thames equal to filling "ten-sail of boats" in these modern days.]

A VINE PROBLEM.

HAVING an interesting if not an important problem in reference to variation in Grapes to solve, I should very much like to have the benefit of the experience and observations of readers of the *Journal of Horticulture*.

- 1, Is there such a thing as a Vine with foliage and wood that cannot in any point or degree be considered to differ from some other Vine, but that at the same time continues to bear Grapes that are quite distinct from that other Vine?
- 2, Are any instances known where a seedling Vine, the produce of a cross between two of the most distinct Vines, differs in no degree whatever from one of its parents in either wood or foliage, but that bears Grapes quite distinct from that borne by the parent with the leaves and wood of which the seedling is identical, and that at the same time has no likeness whatever either in colour or flavour of fruit, or in wood or foliage to the other parent, the parent being one of the most striking and distinct Vines known?
- 3, Do any readers know of any sport from a Vine that has borne and continued to bear Grapes distinct from the original stock, and that on being propagated in the usual way has perpetuated the distinction?

 —AN EXPERIMENTALIST.

[We shall be obliged by replies to the questions propounded by our correspondent.]

NEWNHAM PADDOX.

NEWNHAM PADDOX, the seat of the Earl of Denbigh, is very pleasantly situated on the south-eastern borders of Warwickshire, about three miles distant from Brinklow Station on the L. and N.W. Railway. After leaving the station the road passes through the small village of Stretton-under-Fosse, with its quaint-looking thatched cottages and wayside gardens, where many old fashioned hardy herbaceous plants may be seen growing luxuriantly, and evidently quite at home amid their rustic surroundings. Continuing our journey we shortly reach the small hamlet or Street Ashton, from whence may be seen the picturesque village of Monks Kirkby, with its grand old church tower looming up far above the housetops, presenting an excellent picture for the artist's pencil or the photographer's camera. At the extreme end of the village we find the entrance gate to Newnham Paddox. The mansion, which is approached by a carriage drive nearly a mile in length, winding through a finely timbered park, a splendid avenue of English Elms, which have withstood the storms and gales of time immemorial, being especially noticeable. As we approach the mansion our attention is directed to some massive wrought iron gates, separating the park from the pleasure grounds. These gates, which were brought from his Lordship's estate in Shropshire, are beautifully designed, carrying numerous monograms. They are 24 yards in width, and from 15 to 20 fect in height. these gates is a short drive, about 100 yards in length, leading to the front entrance door, upon each side of which, and planted sufficiently far enough back to allow them to develop into full beauty, are some splendid specimens of Araucaria imbricata, from 20 to 30 feet in height, and branched to their base. The gardens are situated about 200 or 300 yards from the mansion, and are admirably managed by Mr.

Commencing at the glass houses the first range entered consisted of three lean-to vineries, and a similar house in which fruit trees are grown The whole of the Vines were planted by Mr. Harman about five years ago, and the grand crop of fruit and strong healthy foliage showed that he thoroughly understands his business. The Black Hamburghs were carrying a magnificent crop of fruit. Each cane about 15 feet long bearing fifteen bunches, averaging $2\frac{1}{2}$ to 3 lbs. each. Several leaves which I measured were 15 inches across and $1\frac{1}{2}$ inch round at the base of the leafstalk. A large Fig tree on the oack wall was ripening a capital second crop, the variety being Brown Turkey. The second house contains Black Hamburgh and Foster's Seedling, the crop being similar in appearance to that described. A large Vine of Foster's Seedling, covering the whole of the back wall, was laden with grand bunches, the berries being large, and well finished. The third house is composed of Muscat of Alexandria, and presents a sight not easily to be forgotten. Several of the bunches are 20 inches in length, and exceedingly well shouldered, many of them would, I venture to a sert, turn the balance at 6 or 7 lbs. A shanked berry has never been seen in the whole house. The magnificent bunches which secured the

first prize at the Westminster Aquarium and at Birmingham last year were grown in this house. West's St. Peter's on the back wall was also doing well. Mr. Harman is a strong advocate for plenty of light in vineries. The laterals are allowed to extend till the trellis is covered, some of them being six or seven leaves beyond the bunch; in fact, they look more like young canes than laterals. The sub-laterals are pinched back to one leaf, for the purpose of throwing as much energy as possible into the main leader, as he avers there is more support in one primary leaf than there is in a dozen sub-laterals.

The trees in pots were exceptionally good, the varieties being—Plums, Coe's Golden Drop, Jefferson's, and Denniston Superb; Peaches, Alexander, Gros Mignonne, and Crimson Galande; Nectarines, Elruge and Lord Napier; Cherries, May Duke, Mammoth, and Bigarreau Napoleon. The Cherries were over at the time of my visit, and the trees placed out of doors to mature their growth for another season. Alexander Peach, which is looked upon by many gardeners as being subjected to bud-dropping, gives but little trouble in that respect here, both the trees in pots and on the back wall being well cropped. Tomatoes are largely in demand. Sutton's Earliest of All was carrying an extraordinary crop, in fact the plants had to be very carefully tied to prevent them breaking down. The fruit was excellent in shape and

flavour, and of a beautiful red colour.

In another house a number of Veitch's erect flowered Gloxinias were in full flower, making a grand show, a superb flower of pure white being especially noticeable. Sobralia macrantha and Oncidium flexuosum were in bloom. Cattleyas, Vandas, Aërides, Cypripediums, Cologynes and Calanthes are throwand Lælias were well represented. ing up strong pseudo-bulbs, bespeaking a good supply of bloom later on. Cut flowers and plants for decoration are in great demand, but to judge from the excellent young plants of Crotons, Dracænas, Pandanus, Dieffenbachias, and various others the supply is ample. Mr. Harman is no novice in this branch of his business. Ananassa sativa variegata beautifully coloured is a most useful plant for decorative purposes. Eucharises in the pits were in splendid condition, the plants being large and full of vigour, as were also Gardenias growing in 8-inch pots. The plant stove with its Ficus-clad walls contains many good specimens, including Dipladenia amabilis, Clerodendron Balfourianum, and Anthurium crystallinum, with its large and shapely leaves of a velvety green colour lined with crystal white veins. Gloriosa superba trained along the roof, and flowering profusely, presented a striking appearance. huge plant of Adiantum concinnum, by far the largest I have seen, is After passing through a beautiful grotto also deserving of notice. planted with various Ferns and Lycopodiums, we come to the conserva-tory, the centre bed planted with Camellias and Daturas. An immense plant of Habrothamnus elegans trained to one of the pillars is evidently quite at home, being laden with flowers. Luculia gratissima planted out and trained up the back wall was growing vigorously, and bids fair to supply a good display of flowers later on. Zonal Pelargoniums arranged along the front stage were magnificent; the plants were supplied by Messrs. Cannell & Son, and include some of the leading rieties of the day.

The large kitchen garden is enclosed by a high brick wall, planted on both sides with fruit trees. Across the centre of the garden and at right angles with each other run two wide gravel walks, flanked on each side by herbaceous borders. The walks around the garden are bordered with bush-trained fruit trees, which are probably as old as the garden Some of these are taken out every year and replaced by young The trees forming a line of espalier Apples planted last season were making capital progress. One quarter of the garden is devoted to bush fruit, and contains healthy young trees about three years old, and they were laden with fruit of splendid quality. Although so much has been done in the way of renovating the fruit plantations much more has yet to be accomplished. Crops of vegetables of every description were in excellent condition, but special mention ought to be made of a grand bed of spring sown Onions. The varieties principally grown are Sedfordshire Champion, Brown Globe, and James's Kerping. Border Carnations, of which a large number are grown, were showing well for bloom, and from 700 to 800 Gladioli will be most useful later on. As a successful exhibitor of Chrysanthemums, Mr. Harman needs very little introduction, and judging from the fine condition of the plants he bids fair to prove a very dangerous opponent at the forthcoming

tournaments.

Cedars are well represented in the extensive and well-kept pleasure grounds. Stretching away to the east are two large ornamental sheets of water, surrounded by shrubberies and woodland walks. The flower garden is situated on the south-east side of the house. The beds, which are geometrically arranged, were filled with all sorts of summer flowering plants. Zonal Pelargoniums, Tuberous Begonias, Stocks, and Asters are largely grown, and several beds edged with Sedum acre aureum were extremely effective. On the well kept lawn sturdy Yews feather the ground, stately Oaks of noble dimensions, splendid Acacias of great age, and many other trees and shrubs attract attention on our way to the rosery. This is circular in shape, and surrounded by high shrubberies. The beds were made and planted by Mr. Harman two or three years ago, and the display produced must indeed be gratifying to him, and a reward for his labour. Mrs. William Watson, Pierre Notting, Ulrich Brunner, Merveille de Lyon, Baroness Rothschild, Miss Jenne Dickson, Mr. A. Williams, and white La France were particularly effective.

I cannot close these remarks without thanking Mr. Harman for the hearty welcome accorded me, and for the ready manner in which he supplied me with any information I required about the estate—

G. PARRANT, Rugby.

CYPRIPEDIUM ŒNO-SUPEBIENS.

THE Cypripedium depicted in the engraving (fig. 38) is a very bright and handsome form. As mentioned last week it is the result of a cross between C. cenanthum and C. superbiens, and when exhibited by Sir Trevor Lawrence, Bart., at the Drill Hall on September 12th, the Orchid Committee of the Royal Horti-

on September 12th, the Orchid Committee of the Royal Horticultural Society adjudged an award of merit for it. The prevailing colour is a brownish red, this suffusing the petals and lip. The former are bold and spreading, the latter being somewhat pointed. As shown in the illustration the dorsal sepal is broad and imposing. It is heavily lined with chocolate dots and suffused with rose margined with white.

CATASETUM BUNGEROTHI.

THIS, one of the latest introductions amongst the Catasetums, is probably one of the most showy Orchids at present cultivated, by reason of its solid and massive spikes of almost waxy whiteness which last in good condition for some weeks. A fine healthy plant of the above species, carrying three grand spikes, has been in bloom at Cleveley, Allerton, and as it is one very seldom seen, a note as to the excellent system of culture pursued by Mr. Cromwell may be interesting to some readers. plants are grown in baskets suspended from the roof of the stove, the compost used being good peat with the finer particles taken out. When the plants are in active growth a plentiful supply of water is given, occasionally applying very weak liquid manure. When the pseudo-bulbs are matured only sufficient water to keep them from shrivelling is applied. During the winter the plants are kept in a temperature of 60°. If the pseudobulbs are strong they flower very freely.—R. P. R.

THE BLUE DISAS.

HAVING seen in the Journal of Horticulture for this week that "Specialist," on page 237, describes the blue Disa as being of a bluish purple hue, "by no means the

purple hue, "by no means the brilliant blue some might be led to expect from glowing descriptions given in past times of the blue Disas at the Cape," I would like to say that two years ago I was out in South Africa during the month of March, and was then given a bunch of Disas from Table Mountain, amongst them several blue Disas, the flowers of which were certainly not large, but there was no doubt as to their hue; they were unquestionably of a true bright blue. I have never seen the plant in flower in England, but I presume Disa lacera is the same as the blue Disa I saw at the Cape.—A PLANT PILGRIM.

INSECTS OF THE FLOWER GARDEN.

(Continued from page 190.)

THE snouted mites form a small and singular family, one member of which Curtis regards as useful to the farmer and gardener. In this little group we have both land and water species; some have no eyes, and others have them of variable number, from

two to six. Apparently the head is lacking; it takes the form of a snout attached to the thorax, but it is armed with long narrow mandibles, also there is a sucker which is enclosed in a sheath. Our garden species is called Scirus insectorum; it is brownish, has a bristly body and legs, being thereby no doubt able to cling firmly to those insects upon which it is parasitic. This snouted mite is sometimes found adhering to the legs of wandering spiders, but it is more frequently noticed upon the wireworm beetles, the Elaters, and it also infests the Tipulæ or craneflies, so troublesome to us in their larval stage. They occur in parties upon many of the insects to which they cling, and that by their proceedings they must weaken these is obvious; hence they help to diminish the number of our foes.

The ticks, which form the family Ixodidæ, are in our cool climate

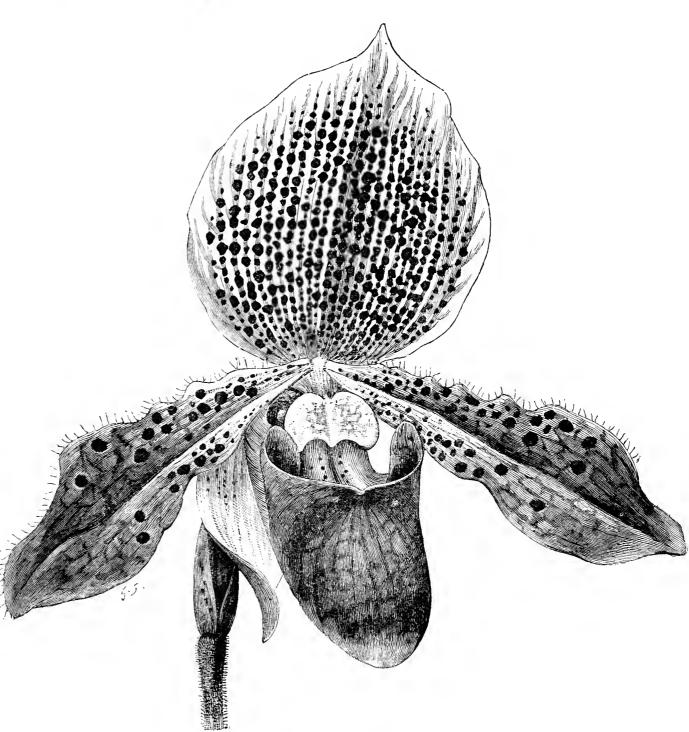

FIG. 38.—CYPRIPEDIUM ŒNO-SUPERBIENS.

of comparatively small consequence, but in warmer countries they are larger, their puncture is more virulent, and they multiply speedily; the rostrum or sucker is barbed, so that it cannot be retracted when it is once driven into the flesh. In habit most species resemble the harvest bugs or mites, that is, they commence life as feeders upon vegetable substances, and afterwards transfer themselves to warmblooded animals or to man. Our native species are eyeless, but this does not prevent them discovering us and gratifying their thirst for blood at our expense. Ixodes marginatus is not uncommon in South England about flower gardens, attaching itself to the grass of lawns and to low plants along borders. Like its brethren, being of a greenish or greenish brown colour it is not often noticed. Many persons have been annoyed by this or some kindred species during the summer of this year, probably owing to the dryness of the season, and have perhaps attributed the irritation to some other cause. The presence of ticks in the flower garden may seem singular; I imagine they are sometimes introduced there by dogs. These quadrupeds frequently swarm with ticks, and they are allowed by some persons to range

their gardens; in consequence the mature insects fall from the dogs and deposit their eggs, the young mites, as already noted, subsisting upon sap at first till they are strong enough to fasten on animals. It is curious that next to dogs the animals most infested by them are bats and snakes. On the Continent people much plagued by ticks have found advantage in applying to the skin strong tobacco water.

The beetle mites of the genus Oribates are little known in

Britain, having rather escaped observation so far, though they may be almost as numerous with us as they are in France. Individuals have occasionally been observed amongst Orchids, or shaken from the moss and sphagnum used in the cultivation of some kinds, and companies have been found under the bark of fruit trees, or hiding amongst lichens. Boisduval considers these mites are friends to horticulture, since he has had proof that they devour the eggs of thrips and other insects detrimental to choice plants. Their name was suggested by their beetle-like aspect under a glass, the body being rounded, black, and shining, with curious hairs or tubercles; the legs have double claws, yet their movements are slow. Also the beetle mites have no eyes, nor a sucker, but feed by means of mandibles. One naturalist says these mites should be "encouraged" if we knew how.

Rather a familiar object to us in country gardens these autumn days is the beetle Geotrupes stercorarius, possessor of several English names, such as the dor, the dumble-dor, and the watchman. We notice it dragging itself laboriously along the paths during daylight, and after dusk it careers clumsily about, having a habit of knocking against our persons, thereby bringing itself to grief. We see the point of one of its names when we take one of these useful beetles up and find that it is weighted with a load of mites, which hold on tightly to the body and thighs. The humble bees that we see visiting the later flowers of the season may be observed bearing about as they fly undesirable companions of the same kind, and though they seem indifferent such parasites cannot tend to the benefit of the insects thus infested. A young lady of my acquaintance sometimes occupies herself in freeing this "shard-borne beetle" from its encumbrances if she comes upon a specimen. It is observable that the mites seldom live long when removed, appearing to be unable to re-attach themselves to another victim. These mites are Gamasids, some of them having the skin horny all over; in others it is soft and pliant. In colour they are yellowish or brown. They have mandibles with nippers, and a sort of sucker peculiar to themselves; also they are eyeless. On the supposition that in their early stage of life they feed upon manure or amongst damp earth, we may understand how, when they change their food, they can soon transfer themselves to beetles and humble bees. Gamasus marginatus is the commonest of the group, being about as large as the head of a good-sized pin. A smaller Gamasid occurs upon some garden beetles, crowded together on the under side of the insect. The mites look like a number of tiny shining scales or cocci. Occasionally they are piled upon each other, and if an attempt is made to remove them it is discovered that every mite is secured by a small tough thread. Some species of this family occur upon the shores of the ocean, and a too well-known very prolific species is the so-called tick that annoys canaries and other small birds, also domestic poultry. This is Dermanyssus avium, and it seems to be a bloodsucker throughout its history. It has been found in colonies of all ages upon birds, and under some circumstances may doubtless infest human beings.

The Hypopidæ are also parasitic upon other insects, specially on many flies that are common in gardens; but some attack beetles and bees. They possess a sucker, though jaws seem to be wanting. The front pair of legs are elongated, and the body is smooth and velvety. They are supposed to undergo some very singular transformations; but these are imperfectly known, owing to the minute size of the mites. De Geir was the first naturalist who noticed them. They were detected by him in 1735 occurring upon house flies and allied species in such numbers that the thorax and abdomen of the insects appeared to have a sort of coating. When removed the mites could run rapidly. Those that live upon beetles sometimes conceal themselves in a cluster under the wing cases; and we must conclude that with these, and still more with flies, the attacks of such mites tend to check their increase, and as parasites they have their utility. Some of the French scientists think that the Hypopidæ may be frequently feeders upon vegetable matters when young, since in 1873 and 1874 the Mushroom crops about Paris sustained damage from a mite which was presumed to be one of these species in an early stage.—Entomologist.

PLAIN WORDS ON PRUNING FRUIT TREES.

OF all the various branches in the art of gardening there is not one which requires more skill and experience than the care of fruit trees. To the world in general this may appear to be one of the easiest of a gardener's duties, to the true gardener it is a pleasant mental and

manipulative occupation. Few amateurs understand the subject of pruning, and being afraid of making mistakes put off the work from day to day, until it is too late to act effectively. Yet amateurs should learn something of the art in question. Every house should have a garden attached capable of producing enough fruit for home consumption, and what more interesting change for a man who has been engaged in a close office or workshop all day than to spend an hour or so in his fruit garden in the evening? The trees must be trained, and useless shoots removed that would obstruct the light and prevent the formatting of facility had a superstant who wishes to learn the restaurant of facility had a superstant who wishes to learn the restaurant of the superstant who wishes to learn the restaurant of the superstant who wishes to learn the restaurant of the superstant who wishes to learn the restaurant of the superstant who wishes to learn the superstant of the supers mation of fruit buds. The amateur who wishes to learn how to prune should try and make acquaintance with a practical gardener who will give him a few lessons. Then the gardening papers distribute useful information. Every person interested in gardening should take in at least one of them weekly, and he will find in a few years that he has made a good investment.

As there are different kinds of trees so there are different kinds of pruning—for instance, summer pruning, winter pruning, and root-pruning, and I should like to write a few plain words about them.

SUMMER PRUNING.

This chiefly consists in pinching back side shoots to induce them to form fruit spurs and prevent overcrowding. It is very important to keep the head of the tree open to admit sun for ripening and colouring the fruit and maturing the wood. A young bush tree may have half a dozen branches, and it fruit spurs are formed on these there will be very little to cut away; but the natural inclination of young trees is to make wood.

The pruner must exercise judgment in determining the shoots to cut away and those he must leave. He must keep well in his mind's eye the future formation of his tree, and not stop the growth of the leading shoots required for extension. If a tree were allowed to grow in its natural manner it would be many years before it would bear fruit. A tree first devotes its energies to making wood, and not until the branches are well developed and vigour subdued does it produce heavy crops of fruit; but as good land is often scarce and dear, and life short, Art must step in and assist Nature to induce early fructification.

Peach Trees in Summer. - These call for more than ordinary attention. All useless wood must be cut away, and the shoots for the next year's crop neatly laid in, as the Peach bears its fruit on the young wood. Shoots that start from the old wood should be encouraged to keep the tree well clothed with foliage; there are no bare branches on a Peach tree that has been well looked after. The shoots for bearing next season must be selected as near the base of the fruiting branch as possible. Do not bruise or in any way damage the tree, for gumming would certainly occur in the bruised part, and eventually the branch

would die, spoiling the shape of the tree.

Fig Trees.—The summer pruning of the Fig consists in thinning out the young shoots similar to that recommended for the Peach. In the Fig tree the embryo fruit is formed near the apex of the shoot late in the summer, therefore it must not be shortened in winter. The best plan to adopt is to lay in two shoots, one for bearing and the other to be cut back, as will be explained in winter pruning. The fruit formed in summer that obtains any size larger than a pea would, if left, drop off in the following spring. If the fruit can be seen in August it will not become perfect in the following season. The best plan to adopt is to rub off all small Figs that can be seen in the month named. Old trees do not make much wood, and in favourable situations produce good

crops.

Cherry Trees.—These require attention during the summer in pinching young side growths to four good leaves, for inducing the formation of fruit buds to form. The upper part of the tree should be pruned a week before the remainder to strengthen the lower branches and check the upper ones, so as to have equality in growth all over the tree. These remarks apply to Sweet Cherries. Morellos require different treatment. They make more slender growths, and generally form fruit buds the whole length of the shoots, oftentimes with only a terminal wood bud. The treatment should be similar to that given to the Peach—namely, young growths laid in to take the place of the fruiting shoots, which are to be cut out in the winter. Standard trees do not require much summer pruning after the tree is formed. Plum trees should be treated similarly to carly or dessert Cherries.

Raspberries.—Suckers should be removed in the summer with the exception of three or four, from which the next year's crop is expected, and these trained to a stake. Those tied to it should also be thinned and evenly disposed for producing stout canes for ripening.

Bush Fruits.—These, whether Gooseberries or Currents, should not be allowed to grow into a thicket in the summer, as that practice prevents fruit, whereas our object is to produce it. This is accomplished by so thinning and shortening the breastwood in summer that the sun can shine into the bushes. Fruit generally follows the sun, barrenness the shade caused by crowding.

Strawberries.—The pruning (if it can be so called) of these consist in cutting away all runners except those required for layering to form new plantations, and after the fruit is gathered all old and useless leaves, to admit light and air to proper ripen the crowns.

Apples and Pears.—The summer pruning of these consists in pinch-

ing the side shoots to four or five good leaves, and subsequent growths to one leaf. This leads to the formation of fruit buds, but care must be taken to leave the leading shoots unpinched; also the formation of young trees must be considered. If the tree was started with four branches, and these shortened in winter, the next year it should have cight; in the summer following care must be taken not to cut away shoots that will be wanted for the formation of the tree. I will next refer to winter pruning .-- A WORKING GARDENER.

(To be continued.)

EARLY FLOWERING CHRYSANTHEMUMS.

THE communication from your able correspondent "P." (page 249) has a tone of sadness about it quite out of keeping with the weather. It appears he would fain see better things than Chrysanthemums, but does not make it at all clear as to how that end is to be accomplished. I journeyed to Westminster on the occasion mentioned by "P. the impression we should see a very fine display of early flowering Chrysanthemums, for there has been no rain to spoil even the outdoor flowers. On arriving at the Aquarium I was disappointed to see the whole exhibits of the National Chrysanthemum Society staged on one table, or perhaps a series of tables at the end of the building. reflected on the numerical strength of the Society, I felt surely there must be something wrong. Where were the collections of groups of plants so much admired in former years? I was eventually told there was no class in the schedule for groups this season at the early Show.

The competition in the cut flower classes was very meagre. Why? I was informed because the prizes offered were not enough to pay the carriage of exhibits any distance. Surely these are not the lines upon which to conduct a National Society. I was glad to see such a beautiful collection of Dahlias, otherwise I should have had my journey for nothing. At the same time, I heartily agree with your correspondent for nothing. At the same time, I heartily agree with your correspondent, when Chrysanthemums are staged in such company they are not very brilliant. Again, where were the numerous new varieties we have imported during the last few years? Some, I know, are acquisitions, having tried them, but why they failed to put in an appearance on such an auspicious occasion is a mystery to me. J. B. R.

SOFT VERSUS HARD COLD WATER FOR PLANTS.

THE above heading does not accurately indicate the point which arose in conversation between Mr. Dunn and myself, and which I thought readers of the Journal might like to discuss. The question was not the relative values of soft and hard water, but whether hard cold water was positively injurious to plants or not. The comparison referred to broadens the discussion somewhat, and others may like to give their opinion upon it, but I will content myself with meeting Mr. Dunn's wishes, and endeavouring to prove that hard cold water is neither an "obnoxious drug" nor "slow poison to vegetation in general."

First, I should like to correct any mistaken impression which may have arisen through your correspondent referring to my having "thought right to divulge" his "secret ideas." These words would imply that I have been guilty of a breach of confidence in having made public what was looked upon as private; but so far from this being the case it was an agreement between us, clearly understood on both sides, that readers of the Journal should have the question placed before them for their experience and opinion to decide the point at issue. I feel sure that the Oakleigh gardener would be the last to wish so unjust an impression to be formed of his words on page 214 as that I had

betrayed his confidence.

There is such a mass of material and such a flood of instances at the command of anyone who looks about him to prove that hard cold water is the very reverse of harmful to plants when judiciously used that only a fraction of them can be quoted. The first I will refer to is one bringing in the twin points of health and freedom from insects. One of the largest establishments for market plants and flowers (not fruit and vegetables) is in the South of London, and one of the features of it is a very large house filled with one of the finest Stephanotises in the country. The growths cover hundreds of feet, and they are a picture of health, the foliage shining with the rich deep hue of perfect condition. No trace of mealy bug can ever be found in this house, which yields thousands of sprays, but no special preparation is employed for cleansing it. The only insecticide used is water, syringed on constantly and forcibly, water from tanks fed by pipes connected with the water company's mains. It is impossible for the insects to gain a footing under the drenchings that are applied. They do not stop to ascertain whether the water is hard or soft, they have no time for arguing that point, although according to Mr. Dunn's theory they would simply indulge in a disdainful sniff at tap water, and then treat it with silent contempt. Do they do this? No, they ignominiously depart. Evidently they are craven-hearted creatures not possessing half the determination of those in the East Grinstead district. "J. B. R." (page 239) has spared me the trouble of more market references.

Then there are the parks. I was admiring Battersea Park a few days ago. The bedding is beautiful, the Chrysanthemums sturdy and healthy. But they do not get soft water. They have been "poisoned"

with hard all through this rainless season. They ought to be dead, but they are alive-very much alive. A more vigorous collection of plantcorpses I never saw. I might even say that, magnificent as are the flowers and Chrysanthemums at Oakleigh, those at Battersea Park are equally creditable to the grower. If this does not draw an admission of error from Mr. Dunn I do not know what will. I feel that it is the most subtle shaft which I can hurl, but still I will make a short reference to the nurseries in order to "pile conviction on conviction's head." the trade establishments this year I have seen hundreds of thousands of plants in perfect health and cleanliness. How does your correspondent imagine that in a season like this, when millions of gallons have been wanted daily, nurserymen have been able to avoid using tap water? Their plants have not succumbed to the "obnoxious drug." Perhaps they are tougher than his.

Lastly, so far as the present communication is concerned, there are the thousands of amateurs before referred to. In towns they use tap, in the country well water. Where it is practicable I agree that they would be wise to expose their water to the sun and air, but my present task is to show that without that they achieve success. The best cultivators among them have clean and healthy plants all the year round, and when they fail it is not because the water is hard, but generally because too The fact of others succeeding with the same much or too little is given.

kind of water is proof of this.

I have said all I have time for, and perhaps sufficient to mcct the case. If not I will try again. There are degrees of hardness in water just as there are in temperature. Water drawn from town cistorns is neither so hard nor cold as that pumped up from the bowels of the earth, but both are beneficial if properly used. In my view hard cold water is a "slow poison" of about the same virulence as tobacco to the old smoker who had puffed at his pipe for sixty years. "Slow," said he. "Yes-very!"-W. P. W.

AFTER reading "J. B. R.'s" article upon this subject on page 239 in your last issue, I feel almost tempted to covet a few gallons of the "hard cold water" that has produced such marvellous results. I am not in the least surprised to learn that "J. B. R." has waited "anxiously" for the opportunity of thoroughly demolishing my "out of date" ideas by such "stubborn facts." What interpretation are we to put upon this word stubborn? The true meaning of stubborn I take is unreasonably obstinate; therefore it strikes me as rather singular in glancing at the commencement and conclusion of his article to find that by "unreasonably obstinate facts he has proved that I am whimsical."

Allow me for a moment to look into these "stubborn facts" The very first one shakes faith and leaves doubts—namely, "J. B. R.'s" assurance that in entering a market garden "where nothing else but cold water was used he found the crops far superior to anything seen in private gardens." His opportunities for seeing the work of some of the best practical men has evidently been limited, and he undoubtedly weakens his case by his statement, which is really a reflection on many of the best cultivators in the world; but it seems evident that he was not trained under them, hence, perhaps, his sweeping dogmatism.

It is acknowledged by practical and scientific authorities that water has a considerable effect in cooling soil, and also that cold wet soil is far from being so fertile as soil that is properly drained. Why? Because the drainage of wet soil results in a greater warmth, and consequently an earlier and more vigorous growth of vegetation. Does not this alone prove how essential it is to keep the soil of growing plants reasonably warm according to the seasons? Will "J. B. R." kindly explain why crops and plants in general grow so much more freely after a warm shower than they do after a cold shower? We shall then be a trifle nearer the actual point. My experience is quite the reverse of "J. B. R.'s" "as to the fertilising properties of hard water." Here is a fact which can be substantiated by one who occupies a high position in the gardening ranks. A Rose house was erected about twelve miles from London, and water laid on direct from the main. The Roses were planted in good substantial soil, and kept constantly watered and syringed with the "hard cold water;" result, a miserable failure. The plants refused to grow, and mildew was constantly appearing. After repeated trials to improve them, a tank was fixed inside the house exposed to light and sunshine. The plants when watered and syringed with this "warm soft water" changed in a few weeks, and in twelve months the Roses were growing vigorously and producing splendid blooms—the Maréchal N cls quickly paying for the tank, and leaving a weighty purse over. Other equally convincing facts can be supplied if space permits.

I have no wish to dispute the point of colour and appearance raised respecting Palms grown for market, but "hard cold water" is not the only stimulant used to produce luxuriant growth, or why do so many turn a pale, sickly colour in a few weeks after being bought? Do they miss the" hard cold water" or the stimulants used to bring them to perfection quickly? I pass over the Grape question, having no wish to bring down the overladen houses upon my head, although I must confess to a lurking disposition to inspect the poorly built structure and cast a critical eye over the "finish" of those heavily cropped Vines which my "slow poison" has stimulated to such an alarming extent. Just a word of advice to "J. B. R." Carefully preserve all articles upon shanking that may appear for presentation to the proprietor of that

large Grape-growing establishment.

Lastly, we turn to Chrysanthemums watered with "hard cold water" by hose, and picture for a moment the effects of this stimulant so lavishly used in contrast to those carefully watered with "warm soft

water." Watch those stern judges as they wander along the boxes of blooms produced by such opposite treatment, and I venture to say without fear of contradiction, that those nurtured with "warm soft water" will be the first to command attention.

I am glad that "J. B. R." finds one "novel" point in my "out of date" ideas. This is curious, and I fail to reconcile the two statements, "Novel" and "out of date." "Novel" I take to mean of recent origin, "out of date" a bygone, exhausted error. Can "J. B. R." explain these somewhat contradictory terms?

I still maintain that "warm soft water," although "novel" to your correspondent, is one of the safest and cheapest insecticides for ridding Peach and other trees of red spider. Allow me to point "J. B. R." to the concluding words of your able and practical correspondent Mr. G. Garner (page 241)—viz., "Avoid the use of cold water." Is not this another convincing proof that my ideas are not based upon imagination or odd fancies, but are purely plain unvarnished truths which no "stubborn facts" as related can prove "whimsical?"—F. DUNN.

JEAN BAPTISTE GUILLOT.

This distinguished rosarian who has just now passed away is the third of those French raisers whom we have recently lost, and was certainly the foremost of the three in the services which they rendered to horticulture. Margottin and Charles Verdier have left behind them but one or two Roses that are likely to perpetuate their names; not so, however, Guillot, the raiser of Horace Vernet and La France amongst Hybrid Perpetuals, and Catherine Mermet, Edith Giffard, Comtesse de Nadaillac, Ernest Metz, Etoile de Lyon and Madame Hoste varieties, which will long, I believe, perpetuate his memory, and which have won him the lasting gratitude of all lovers of the Rose.

It is many years since I made his acquaintance. His father was then alive, and we used to call him young Guillot, though he must at that time have been forty years of age. He was an amiable and much respected honest man, and the high position of most of the Roses he sent into commerce is in itself an ample testimony to the correctness of bis judgment. He was not actuated merely by the considerations of pecuniary gain that his Roses might bring to him, as the following incident will illustrate. When I visited his garden, after showing me his other treasures, he said, "I have here a Rose which I think will be the parent of a new race," and he brought me over to see the seedling plant of La France. I was so taken by it that I ventured on behalf of a London nurseryman to offer him a sum of money which would have been considered by many Frenchmen as quite a fortune. "No," was his reply, "I will not part with it. I believe it will perpetuate my memory, and so I would rather it should go out as mine." I cannot but think he was right. In one thing, however, so far, he was somewhat too sanguine, for La France has up to this time never given a pod of seed, although I hear that Messrs. Dickson & Son of Newtownards have a seedling from it.

Lyons was so far south, and the journey is a long and tedious one, that English resarians did not come in contact with him so often as they did with his Parisian confrères. Thus while I frequently visited Margottin and Verdier, I paid only one visit to Guillot. But all who did so can bear testimony to the fact that he was an intelligent and pleasant companion and an enthusiast in his love of the flower for which he had done so much.—D., Deal.

OSIERS.

It has been represented to the Board of Agriculture that it would be useful that they should obtain and publish some information respecting the cultivation of Osiers, with a view to direct the attention of agriculturists and others to a special industry for which there would appear to be some room for development in certain parts of this country. The Board have, therefore, collected certain particulars, and have obtained a report by one of their Inspectors—Mr. W. C. Little of Stags Holt, March, who was assisted in his inquiries by Mr. J. Brown of Wisbech as to the conditions under which Osier growing is now pursued in the Fen districts, from which the following notes have been compiled.

There are no official records of the quantity of Osiers imported into this country, but it has been estimated that some thousands of tons are received from abroad annually. There is also said to be a large and increasing importation of baskets. The number of baskets required for the fruit industry alone is considerable, and it must increase with the extension of fruit cultivation. Formerly the fruit was generally packed in baskets made of red or unpeeled Osiers, but white Osier baskets are almost invariably used now.

Osier Willows are grown in nearly every country in Europe. cultivation has received special attention in France, Belgium, Holland, parts of Germany, and South Russia.

In France Osiers occupy large areas in the valleys of the Aisne, Oise, Loire, Gironde, and on the banks of the Dordogne and Rhone. The basket Osier (Salix viminalis) is largely grown in the departments of Aisne and Ardennes.

The area under Osiers in Belgium, according to the latest official returns, amounts to 11,036 acres, the larger portion of this surface is in the provinces of Antwerp and East Flanders, which have 3780 and 2811 acres respectively.

In Bavaria great efforts have been made to improve the cultivation of Osicrs, and the area devoted to Osier holts in that country is steadily

increasing.

OSIER GROWING IN THE FEN COUNTRY.

The term Osier is popularly used as comprehending all the trees or shrubs of the Salix genus, which are cultivated as a crop to be converted by the basket maker and similar craftsmen into various articles which are known as wickerwork. The genus Salix includes Willows, Sallows, and Osiers. Most of the kinds grown for a crop in the Fen district are, it is stated, really Willows, and not Osiers. At any rate, while growers use the term in a collective sense they limit the term when distinguishing sorts of rods to a coarse growing, softwooded species, which peels indifferently, and is only grown in limited quantities for a particular purpose.

Osiers are grown in enclosed plantations, which are locally known as holts. The produce of the Osier holt is known commercially as

"rods.

Green rods are fresh cut and unpeeled.

Brown rods are those which have been left to dry in their skins. White rods are those which have had the bark removed or peeled. Buff rods are produced by boiling brown rods and then peeling them;

but the colour thus produced is imitated by dyeing.

In the Fen district the growth of Osiers is chiefly carried on in unembanked river valleys which are subject to flooding. A variety of circumstances contribute perhaps to this situation being almost universally selected. It is not merely that this is the natural habitat of the genus, and that the soil is suitable, but the convenience of having close at hand water carriage for a bulky and heavy crop, which must be for the most part removed in a green state, has no doubt tended to restrict the growth of Osiers almost entirely to the borders of rivers. An additional reason for the selection of such sites is, that the periodical winter floods bring down from the uplands a considerable quantity of soil, which acts as a fertiliser and is obtained at a comparatively cheap rate. Floods, however, are occasionally the cause of considerable injury to the holts. An ice flood cuts the rods and seriously damages them. Sheet ice settling down on the holt will entirely destroy a crop, and a spring flood, which entirely covers the young shoots, will kill them; but freshets, which disappear quickly and which do not rise above the tops of the rods, do no harm.

The area of Osier holts in the district in question has been approxi-

mately estimated as follows:-

In the Ouse Valley, between St. Ives (Hunts) and Denver (Norfolk) In the Cam Valley, near Cambridge and Ely 190 acres. 108 In the Nene Valley, in the neighbourhood of Peterboro' In the Welland Valley, around Spalding and ... 130 Crowland

But these estimates exclude considerable areas above St. Ives, Peterboro', and Cambridge.

Ely and Earith are centres of a considerable growth of Osiers, of rod

peeling, and of basket making.

There can be no doubt that the extent of Osier holts in the Fen district is now much less than it was; but at the present moment there is some evidence of increased interest in the subject and greater attention to the business. The industry is apparently becoming more of a speciality, and basket makers are planting holts in some instances to supply their own requirements.

THE CULTIVATION OF THE OSIER.

The most suitable soil for the growth of Osiers is a deep, rich, moist, alluvial soil. Any good clay may be planted if sufficiently moist. Peat moor and hot gravels are absolutely unsuitable. Though water is requisite, a holt will not thrive in stagnant water.

The site of a holt having been selected, the land must be thoroughly cleaned during the summer before planting, and it may be worth while to give it a complete summer fallow. Before the winter sets in it must be thoroughly stirred either by digging or ploughing to a depth of 14 or 16 inches.

If the soil is not naturally rich it should be manured, and soot is

said to be a good preparation for the crop.

Planting should be done in February or March. The sets are cut from wood of two years' growth—they should be 16 or 18 inches long, and about 10 inches of the set should be in the ground. During the spring and early summer the spaces between the rows must be kept clean by hoeing and forking. The cleaning must be completed before the middle of June, or the Osiers will be injured. The cost of cleaning is variously estimated at from £1 to £2 per acre per annum for the first two years. After that time the expense of cleaning is much less, as the dense and rapid growth of the Osiers stifles and smothers all other vegetation. It may be mentioned in passing that the young shoots from

an established stock will make a growth of 18 inches in the course of a

Under the most favourable circumstances the newly planted holt will be at maturity in three years, but as a general rule four or five years

must elapse before its full development.

A holt properly planted, kept clean, regularly filled up, and well managed will last from ten to fifteen years, the duration depending upon the sorts planted and various circumstances which affect the several kinds of Osiers in different ways.

The Willows and Osiers usually grown in the Fen district are known locally by names indicative either of some characteristic of the tree or of the country from which it has come. The favourite sorts are :-

Glibskins.--In some situations this kind is particularly liable to "scab," a disease to which reference is made later on.

Black Mauls. - Small, but hard and tough, and consequently

valuable.

Green Sucklings .- A heavy cropper, but not liked by the basket maker.

Welsh Osier.—This has a very bitter rind, which is disagreeable to all animals, and it is planted on the outsides of holts.

Black Hollanders, Mottled Spaniards, Cane Osiers, and Dutch Red.

A certain proportion of the coarse-growing Osiers may be grown, as the basket makers require some strong stout rods for uprights; where they are not grown their place is supplied by leaving a portion of the holt to grow for two or three years.

The cost of preparing and planting an Osier holt is variously estimated at from £14 to £23 an acre—the amount depending upon whether the land is trenched or ploughed and upon the preparatory cleaning which may be necessary.

Taking an outside estimate, the items of expenditure would be as

follows :-

Fallowing ... \dots £4 0 0 an acre. 8 Trenching -0 - 0,,, Sets, 20,000 at 10s. per 1000 10 - 0Planting 1 0 0 £23 0 0

This is without any allowance for manure.

On the other hand, if fallowing is not required and ploughing is

resorted to, the cost would not exceed £14 an acre.

The Osiers attain to their full growth by the middle of September, by which time the rods on established plants will have made a growth of 6 to 7 feet. Osiers and Sallows will make an average growth of 8 or 9 feet, and occasionally as much as 13 feet, in a single season.

Cutting the rods commences with the new year if the holts are accessible. Sometimes, however, floods or other circumstances prevent the early cutting, and the process has to be postponed. It is, however, considered very desirable to cut before the sap rises, as the stocks bleed, and the new growth is less vigorous if the sap has risen before cutting. The rods are cut with a sharp hook, somewhat like a strong reaping hook; a clean cut without splitting the rod is essentially necessary. As the rods are cut they are tied up by willow bands into bundles or "bunches." Each bunch has a girth of 45 inches (an English ell) at a distance of 1 foot from the butt end of the bunch. The "ell band" is secured in its place by attachment to another band, called the "breech band," round the butt end. A third band is placed higher up. The cutting is paid for by the score bunches, the ordinary rate being 2s. 6d. An average crop will be about 150 bunches, and a heavy crop will reach to 250. A green bunch will weigh 6 stones. The weight of rods per acre will range from 5 to 10 tons.

It has already been observed that it is a great advantage if this

bulky and heavy crop can be removed by water carriage.

If the rods are to be peeled they are conveyed to the peeling yard and placed with their butt ends in water, where they remain until the rise of sap makes the peel separate easily from the stick. Sometimes after the rods are cut they will dry from exposure to the air, and in that case they are put in a heap, watered, covered and sweated, or "couched" as it is called. If the rods in the pits get too advanced in growth before peeling the difficulty of peeling is increased, and the rods are damaged. The work of peeling begins as soon as any of the rods are fit. It is chiefly done by women, who draw the rods through a "break" or "cleave," which divides the bark into strips, which are removed by the hand. The children of the peelers assist in this latter operation.

As the rods are peeled they are sorted into three grades—"large," "Middlesboro," and "small" rods, according to their size and length. They are then exposed to the air for a short time on racks, or reared against hedges or walls. When dry they are tied up in bunches of the

same dimensions as before, and stored away in sheds.

Rods which are adapted for the purpose, and which are, in consequence, most valuable, are subjected to another process known as "skeining." This is the longitudinal division of the rod by splitting it into equal parts. The thick end of the rod is nicked with a knife, dividing the circle into three sectors. A triple wedge is then inserted, and the rod is drawn rapidly through the hand. The split canes are then drawn twice under a knife fixed to a gauge to remove the outer ring and inner angle, and the cane is reduced to a flat thin strip of equal thickness. These "skeins" arc used for weaving sieve and riddle bottoms, and for making basket handles and similar articles. Green rods are "skeined" by the same process for making ecl grigs and hives.

(To be continue.)

CODONOPSIS (GLOSSOCOMIA) OVATA.

THE plant represented in the engraving (fig. 39) was introduced under the name of Glossocomia, but which has been superseded by that of Codonopsis in the "Genera Plantarum." It is easily cultivated after the seedling stage has been passed, a good plan being to sow the seed in pots in a heated frame, pricking out the young plants as soon as they are large enough in boxes or pans, planting them out the following spring, but guard against breaking the very brittle roots.

The choice of position will be the next consideration; the sunniest and most exposed that can be selected will be the best, planting them 6 inches apart, and the roots must not be disturbed by digging. The flowers are large, as may be seen, but are best viewed at a distance, the

FIG. 39.—CODONOPSIS (GLOSSOCOMIA) OVATA.

odour being anything but agreeable, and resembling somewhat that of the Aristolochia; the colours inside the flowers are very pretty and curiously blended. This is one of the few flowers, we believe, that are self-fertilising, that process being accomplished before the flower opens by a curious movement of the anthers. It ripens seeds freely, and is readily increased by that means. It is a native of Northern India, and flowers during the summer.

HORTICULTURAL SHOWS.

EDINBURGH.—SEPTEMBER 13TH AND 14TH.

THE autumn Show held annually in connection with the Royal Caledonian Horticultural Society took place on the above dates. The exhibits were numerous though not so much so as in previous years, this being more especially noticeable in the classes for Grapes. Apples were as a whole the best feature of the exhibition, though vegetables were well shown. Amongst these latter Onions were exceedingly good. The arrangements of the Show were not praiseworthy in any way, the utmost confusion prevailing. The judges had much difficulty in finding the classes, and the work of reporting was rendered arduous; in fact it was found impossible owing to the manner in which the exhibits were arranged to give a full account of the prize winners, and those who were successful in the principal classes only are named in the appended list. During the two days about 20,000 people visited the exhibition.

FRUIT.

As already stated, Apples were the chief feature of the Show. Grapes, on the other hand, have not for many years been so poorly represented at any of the autumn meetings of this Society. Some of the exhibits were of exceptional merit; but generally, the quality, like the numbers shown, was below the average. Collections of fruit, again, were only few in number. Pears were staged in large numbers, but in quality they were generally inferior to Apples, among which were many dishes of exceptional merit. Few Peaches were shown, and fewer Nectarines and Figs, though Plums, notwithstanding the early nature of the season and the unremitting attention of wasps, were fairly well

represented.

Taking the collection of fruit first, that of twelve dishes, excluding Pine Apples, was the chief item, and for the handsome prizes offered only three competitors staged. The first prize was awarded to Mr. Hunter, Lambton Castle, Durham, who had some very fine fruit. The Grapes comprised two very large clusters of Gros Guillaume, each in beautiful condition, a pair of large-berried examples of Gros Colman, and a couple of bunches of Raisin de Calabria. Peaches were Exquisite and Noblesse, both very fine, a dish of splendid Beurré Diel Pears, fine King of Pippin Apples, Challenger Lemons, Hero of Lockinge Melon, the other dishes being rather poor examples of Nectarines, Plums, and Figs. Mr. A. Kirk, gardener to — Paton, Esq., Alloa, was a close second. He showed black Grapes only, these being extra fine Alnwick Seedling, fine Gros Maroc and Black Hamburgh. Among the other dishes were good examples of Pitmaston Duchess Pear, good Barrington and Walburton Admirable Peaches, Spense's Nectarines, and Worcester Pearmain Apples. Mr. McKelvie, gardener to the Duchess of Roxburgh, Broxmouth Park, Dunbar, was the other exhibitor, and to his collection the third prize was awarded. Extra fine Muscat of Alexandria and Souvenir du Congrès Pears were the outstanding dishes.

For a collection of dishes of fruit, including Pine Apples, there were again three entries, Mr. Hunter repeating his victory. The Grapes comprised good Gros Colmans and somewhat loose Raisin de Calabrias, fine Noblesse Peaches, extra Beurré Del Pears, fine Magnum Bonum Plums, Hero of Lockinge Melon, extra fine Cox's Pomona Apples, and small Victoria Nectarines. Mr. McKelvie was second with good Muscat of Alexandria and Madresfield Court Grapes as the chief dishes. Mr. Morrison, Archerfield, Drew, third. Only two collections of hardy fruit, grown in the open air, were staged. Of these the best were shown by Mr. Goodfellow, Kinfauns Castle, Perth, Peaches Dr. Hogg and Prince of Wales, and Souvenir du Congrès Pears being very fine, the same collection containing also dishes of good Magnum Bonum Plums and Morello Cherries. Mr. McIntyre, Darlington, staged the other collection, to which the second prize was awarded. For a collection of twelve dishes of orchard house fruit, again there were only two exhibitors, Mr. Hunter securing first prize with a superb fruit, comprising Pears Souvenir du Congrès and Pitmaston Duchess, Apples Ribston Pippin and Peasgood's Nonesuch, Nectarine Peach, Plums, Figs, and Passiflora edulis, Mr. Bowman, Pittendreich, the other exhibitor, securing the

second prize.

In the Grape classes the most important was that for six bunches. Five exhibitors staged in this class, the first prize falling to Mr. Kirk for large and fine clusters of Gros Maroc, Cooper's Black, Madresfield Court (two bunches), an excellent bunch of Duke of Buccleuch, and a less noteworthy cluster of Black Hamburgh. Mr. Leslie, Pitcullen, Perth, was a very close second, staging two extra fine examples of Muscat of Alexandria, good Gros Maroc, and Alicante. Mr. Hunter third, with splendid Gros Colman, Black Alicante, and Gros Guillaume, the latter having berries very small in size. Five staged in the fourbunch class, Mr. Leslie worthily securing first prize here with extra Gros Maroc, a cluster of well-finished Muscat of Alexandria, good Alicante, and Madresfield Court. The second prize was awarded to Mr. J. Caldwell, gardener to J. Scott, Esq., Langholm, for good Muscat of Alexandria, Gros Colman, and Madresfield Court. Third Mr. McKelvie with bunches somewhat loose.

There was a keen competition in the class for two bunches Muscat of Alexandria, the first prize being awarded to Mr. McKelvie for good and well-finished clusters. Mr. Leslie was second with bunches little behind the first prize exhibit. For one bunch Mr. Waldie, gardener to W. H. Dobie, Dollar, was first with a well-finished bunch. Hamburghs throughout were deficient in quality, though numerously ntaged. Mr. Dickson, Alyth, was first for these; and Mr. Murray, Polmont, second. For one bunch Mr. Ch. Blair, gardener to Col. Malcolm, Langholm, was first. Alicantes were very good, the bunches large and well finished, Mr. Leslie having the best, and Mr. Caldwell a good second. Mr. Green was first for Alnwick Seedling with a small, well-ripened example. Mr. Jeffrey, gardener to Earl of Harewood, Harewood Hall, in a well-contested class, was first with a superb bunch of Gros Colman, the berries very large and of high finish. Mr. Murray second with good examples. Lady Downe's, on the other hand, were presented in poor condition, Mr. Murray being first in this class. For a bunch of any other sort Mr. Kirk was first with an exceedingly fine bunch of Madresfield Court. Mr. Lunt second with Mrs. Pince. In the corresponding class for white Grapes Mr. Caldwell, with a very highly finished Duke of Buccleuch, secured the first prize, and Mr. Smith, Arundel House, second. Mrs. Pince was the finest flavoured black

Grape, the best flavoured white being Muscat of Alexandria, Mr. Leslie staging the former, and Mr. Winter, Walk House, Hull, the latter. Mr. McIntyre, The Glen, secured first prize for the bunch of Grapes with finest bloom, showing Black Alicante. Mr. Crichton,

Southfield, second with Trentham Black.

Mr. Lunt, Kier House, Dunblane, staged twelve beautifully coloured fruits of Late Admirable Peaches, securing therewith first prize, Mr. Melville, with equally good, though pale coloured Princess of Wales, being second. Plums were fairly good. Mr. Cairns, The Hirsel, Coldstream, secured the first prize for seven dishes of rather small fruits of dessert sorts, and Mr. Goodfellow, with a like number of varieties, the first prize for a collection of culinary Plums. The latter comprised Goliath, Magnum Bonum, Pond's Seedling, Coe's Golden Drop, Victoria, and Blue Impératrice. Pears were also good, much better than usual, and a very large number of dishes were staged in the gross for the several prizes. For a collection of six sorts Mr. Day, Galloway House, Kirkcudbright, was first with extra fine Pitmaston Duchess, Souvenir du Congrès, Williams' Bon Chrêtien, Beurré Diel, and Marie Louise. Mr. Campbell, gardener to Lord Swansea, Singleton, South Wales, was second with fine Pitmaston Duchess, Louise Bonne of Jersev, and others. Mr. Day was again first for six dessert Pears with good Williams' Bon Chrêtien and Beurre d'Amanlis. The same exhibitor a so secur d first for dishes of Marie Louise, Beurré d'Amanlis, and Pitmaton Dochess. Mr. Paterson, gardener to A. Fletcher, Esq., Salton Hall, was first in the class for six Williams' Bon Chrêtien with excellent Souvenir du Congrès (was this overlooked by the judges?) and also for a dish of Glou Morçeau. Mr. Campbell had the best Louise Bonne, and Mr. Chaplin, Springwood Park, Kelso, the best stewing Pears with fine Gros Calabasse.

In the Apple classes the collection of twelve sorts was the most important, and brought together a disp'ay of fruit rarely seen in Scotland. Mr. Campbell, Singleton, was first for these with good well coloured examples of Alfriston, Mère de Ménage, Emperer Alexander, Blenheim Orange, King of Pippins, Peasgood's Nonesuch, Worcester Pearmain, Cellini, and others. Mr. Culton, Castle Douglas, was second with better fruit less highly coloured, Ringer, Bismarck, Warner's King and New Hawthornden being specially good. Mr. Cairns, The Hirsel, was third. Mr. Fowler, Merton House, St. Boswells, secured first prize both for six dessert and six culinary Apples with Peasgood's Nonesuch, splendid examples no doubt, but hardly in the same matured condition for dessert as many other sorts on the tables. Mr. Brown, Abercairney, was second for six dessert Apples with fine fruits of Worcester Pearmain and James Greive of culinary Apples. The sorts mot numerously, and at the same time best represented by handsome samples were such popular sorts as Ecklinville, Stirling Castle, Warner's King, Tower of Glamis, Lord Suffield, and Hawthornden, and of dessert Apples, King of Piopins. Cox's Orange, James Greive, and Ribston Pippin. Messrs. Campbell, Singleton; Culton, Castle Douglas; Day, Galloway House; Brown, Abercairney, and Fender, Autoguhey, secured the chief prizes for the several varieties.

PLANTS.

In the class for four Adiantums Mr. Farquhar, gardener to R. Croall, Esq., Blackhall, was deservedly awarded the first prize, staging A. pentadac ylon, A. gracillimum, A. cuneatum, and A. Flemingi in good con-The second and third prizes were awarded to Mr. Napier, gardener to P. Neill Fraser, E.q., Murrayfield, and Mr. A. Crichton, gardener to Mrs. Croall, Southfield, Liberton, in the order of their names. For six Hollies Messrs. J. Dicksons & Son, nurserymen, Edinburgh, were accorded the first prize for handsome specimens. Messrs. R. B. Laird and Son, nurserymen, Edinburgh, were the only exhibitors in the class for twenty-four evergreen shrubs, and were given the first prize. were two competitors in the class for a table of plants, and Mr. McIntyre, Darlington, was placed first with a light graceful arrange-The table was principally covered with Crotons, Dracænas, Ferns, Palms, Lilium lancifolium (speciosum), Bouvardias, and a few Orchids. The second prize was won by Mr. Wood, gardener to J. Buchanan, Esq., Oswald Road, Edinburgh, whose table was composed of very fine plants, better in many cases than those of Mr. McIntyre, but lacking the taste in arrangement which was so prominent in the first prize stand. The premier prize in the class for three Fuchsias went to Mr. Thomson, gardener to G. Gray, Esq., Dalkeith, who staged highly creditable specimens. Mr. Aitken, Rosebery Cottage, Balerno, was a good second, and Mr. Fraser, gardener to the Misses Horn. Canaan Park, third. Mr. Anderson, gardener to Colonel Davidson, Edinburgh, was placed first for one Fuchsia, his plant being very finely grown and profusely flowered. A very close second was found in Mr. Sutherland, gardener to - Mather, Esq., Edinburgh, Mr. J. Dickson being third.

In the class for six dwarf British Ferns Mr. Anderson with very beautiful plants was first, staging Asplenium septentrionale, Scolopendrium Kelwayi, Polypodium cornubiense, P. cambricum, Allosorus crispus, and Trichomanes radicans. Mr. J. Cumming and Mr. McPherson were second and third respectively. Mr. Cropper, gardener to W. B. Boyd, Esq., Faldonshire, was first for twelve dwarf British Ferns; prominent amongst which were Polypodium cambricum, Asplenium Trichomanes incisum, and Scolopendrium Robinsonianum, the second prize going to Mr. Johnstone, gardener to Miss Fulton, Morningside, who had some very charming plants. Mr. R. Muirhead, gardener to W. Ivory, Esq., Edinburgh, was placed in the premier position for three Begonias, showing very beautiful examples, all clean and finely grown. Mr. Thomson was placed second, and Mr. Taylor, Musselburgh, third. For six Begonias the first prize went to Mr. D.

Adams, who showed highly creditable examples. Mr. Henderson' gardener to W. Macfie, Esq., Cleominster, was second, and Mr. Pearsongardener to Lady Lucy Dundas, third. In the class for three bronze Pelargoniums Mr. Gibb, gardener to Mrs. Edmondston, Edinburgh, was a good first, Mr. Anderson being second, and Mr. Cowan, gardener to

Mrs. McDowall, Edinburgh, third.

Mr. Bald, gardener to J. Menzies, Esq., Grangetown, was first for four Pelargoniums in flower, Mr. Muirhead taking the second place. For three Zonal Pelargoniums Mr. McKenna was first with good plants, Mr. Gibb being second, and Mr. Fraser third. In the class for six foliage plants, exclusive of Palms, Mr. Lunt, gardener to A. Stirling, Esq., of Keir was first, his Dracæna Youngi being particularly good. The second prize was awarded to Mr. Crichton, and the third to Mr. W Bennett. Mr. McIntyre, Darlington, was first for six greenhouse flowering plants, Clerodendron Balfourianum and Eucharis amazonica being conspicuous. Mr. Bennett was second, and Mr. Criehton third. Mr. Wilson was accorded the premier position in the class for six foliage plants in pots not exceeding 9 inches, Crotons being noticeable amongst others. Mr. McIntyre, gardener to Sir C. Tennant, Bart., was second, and Mr. McIntyre, Darlington, third.

CUT FLOWERS.

In the competitive classes cut flowers were not very largely shown, especially stove and greenhouse blooms. This was not, however, the case with regard to the Dahlias and the Roses, these being exhibited in great numbers and in grand condition. In the class for thirty-six Roses Messrs. J. Coeker & Sons, nurserymen, Aberdeen, were a good first, staging exceptionally good examples of Victor Verdier, Alfred Dumesnil, Horace Vernet, Comtesse de Nadaillac, Souvenir d'Elise Vardon, Madame Lambard, and Alfred Colomb; Mr. Croll, nurseryman, Dundee, being second. Messrs. Coeker & Son were again first for eighteen Roses, and Messrs. Thos. Smith & Son, nurserymen, Stranraer, second. In the class for twelve Roses the order was reversed, Messrs. Smith & Son being first, and Messrs. Coeker & Son second. For twelve Fancy Dablias Mr. M. Campbell was first with perfect blooms of Silver Prince, Rev. J. B. M. Campbell, Comte de la Saux, Comedian, Madame Soubeyere, and Frank Pearce, the second prize going to Messrs. J. Coeker & Son. Mr. M. Campbell was also first for twenty-four Show Dahlias. staging Mrs. Morgan, Reginald, Wm. Powell, Dandy, Majestic, Maud Fellowes, T. W. Girdlestone, Mrs. Humphries, Colonist, Duke of Fife, R. T. Rawlings, Jas. Coeker, Muriel, W. H. Wil'iams, Mrs. Wm. Slack, John Hickling, Mrs. Gladstone, Nellie Cramond, Agnes, Ethel Britten, Queen of the Belgians, Mrs. Langtry, John Walker, and a seedling. Messrs. Coeker & Son were a highly creditable second.

VEGETABLES.

The classes for vegetables were as a rule very keenly contested, though the number of entries in many of the leading classes did not reach those which have been staged at previous shows. For a collection of vegetables there were eight competitors, Mr. Harper, gardener to J. R. S. Richardson, Esq., Perth, being first. This stand was composed of Sulham Prize Celery, Winningstadt Cabbage, Dobbie's Champion Leek, Autumn Mammoth Cauliflower, Cranston's Excelsior Onion, Long White Marrow, Scarlet Intermediate Carrots, Matchless Marrowfat Peas, Lockie's Perfection Cucumber, Canadian Wonder Beans, Satisfaction Potatoes, and Glenhurst Favourite Tomatoes, all of which were in fine condition. Mr. Johnstone, gardener to T. Laidlaw, Esq., Hawick, was second, and Mr. Rae, gardener to Captain Scott Kerr, Sunlaws, a good third. Mr. J. Waldie, gardener to W. H. Dobie, Esq., of Dollarbeg, was first for six Cauliflowers, showing grand heads, Mr. Abbott, gardener to C. M. Burns, Esq., Prestonfield House, Edinburgh, being a good second. There were seventeen competitors staged exhibits in this class. For a dish of twelve Tomatoes Mr. Murray, gardener to T. L. Learmouth, Esq., Polmont, was first with grand fruits, Mr. Jeffrey, gardener to the Earl of Harewood, Harewood Place, Leeds, being second, and Mr. Hunter, gardener to the Earl of Durham, Lambton Castle, a good third. Mr. Waldie was first with six Cabbages, and Mr. Thomson second. The competition was very keen, there being eighteen exhibits staged. For a brace of Cucumbers Mr. Waldie was again first, the second prize going to Mr. P. Mains, Polmont. Mr. J. A. Murie, Craigmillar Gardens, Edinburgh, was a good first for six Savoys, Mr. Goodfellow, gardener to E. A. Gray, Esq., being a close second.

Mr. Ramage, gardener to J. C. Hope Vere, Esq., Blackwood House, Lanarkshire, was first for twelve Onions, Mr. McKelvie, gardener to the Duchess of Roxburgh, Broxmouth Park, Dunbar, being a very close second. There were twelve dishes staged in this class, magnificent produce being displayed in each case. Mr. Gourlay, gardener to G. Caldwell, Esq., Loanhead, was first for four Beets, and Mr. G. McKenna second. For a collection of six dishes of Potatoes Mr. J. Gentleman, Armadale, was first with Reading Russet, Jeanie Deans, Up To Date, Colossal, Fairlie Castle, and Abundance; Mr. J. Riddell, Chapelton, being a good second. Mr. J. Gemmell, Flakefield, Chapelton, was first for twelve dishes of Potatoes, staging Fair Maid, Post Master, Triumph, The Foreman, The Herd Laddie, Miller's Bountiful, Sutton's Matchless, Windsor Castle, Reading Russet, Pink Perfection, and Abundance. Mr. Wilson, gardener to R. B. Archibald, Esq., Tillicoultry, was second, and Mrs. Ormiston, gardener to G. Pott, Esq., third. For six Turnips Mr. Anthony was first, and Mr. Ormiston second. Mr. R. Moffat, McIrose, was first in the class for six Parsnips, Mr. Logan, Coldstream, being a very good second. Mr. Logan staged six heads of Celery, and was deservedly accorded the first prize, Mr. Waldie being a very close

second. The Brussels Sprouts staged by Mr. Murie, for which he was awarded the first prize, were highly creditable, as also were those of Mr. Brown, who took the second place. Mr. Abbott was first for six Lettuces, and Mr. Lunt second.

MISCELLANEOUS EXHIBITS.

Many of the leading Scotch nurserymen staged exhibits which altogether formed a great attraction to the Show. Messrs. Thos. Methven and Son, 15, Princess Street, Edinburgh, arranged a magnificent table of plants, consisting of Lilium speciosum, Crotons, Caladiums, and Dracænas, all of which were in excellent condition. A table of Begonias, also staged by Messrs. Methven, was one of the brightest ornaments in the Exbibition. Another very fine stand was that of Mr. M. Cuthbertson, nurseryman, Rothesay. Some grand Onions were shown, and the Cuthbertson's New Hybrid Leek were by far the best in the Show. The floral part of this exhibit was composed of very fine Marigolds, Gaillardias, Coreopsis grandiflora, perennial Phloxes, Heliantbus multi-florus maximus, and Pyrethrums. Messrs. Dobbie & Son, Rothesay, had an exhibit, of which the Dahlias-Show, Fancy, Pompon, Cactus, and Single—were by far the best features. Messrs. Jas. Cocker & Son, Aberdeen, staged some very fine Mrs. John Laing Roscs, and Lilium auratum rubro-vittatum amongst other things. Mr. John Downie, Murrayfield, had a highly creditable and tastefully arranged table of plants, amongst which the most prominent were Liliums, Dracænas, Palms, Crotons, and Begonias. Messrs. Cunningham & Fraser, Edinburgh, had two tables of plants, one comprised of hardy plants, and the other of stove and greenhouse plants in variety. Some handsome Hollies were also staged by the same firm.

Ferns were staged by Messrs. Birkenhead, Sale, Manchester, in fine condition. Conspicuous amongst them were Athyrium f.-f. concavum, Adiantum tinctum, A. peruvianum, A. speciosum, Gymnogramma Pearcei robusta, and Asplenium australasicum. Messrs. J. Dickson and Co., Edinburgh, arranged a striking collection of flowers and fruit, in which Violas, Chrysanthemums, Asters, Liliums, Apples, and Pears were the best. Messrs. Alex. Kerr & Son, Roxburgh, showed some grand Cockseombs, and Mr. John Forbes, Hawick, some Carnations, Pentstemons, Stocks, and Phloxes, which were very beautiful. Mr. M. Campbell, High Blantyre, staged Carnations, Dahlias, Michaelmas Daisies, and Pansies, amongst which the Show Dahlias were perhaps the best. Mr. Alexander Lister, Rothesay, showed Pansies in grand condition, good French Marigolds, Dahlias, and Anemone japonica alba. Messrs. R. B. Laird & Son's stand of Dahlias, tastefully arranged with Asparagus plumosus, was one of the most charming in the Show. Messrs. Alex. Cross & Son, 19, Hope Street, Glasgow, arranged a stand of their fertiliser, one, it may be added, of much merit. They also showed a new sprayer they are now offering, which appears to be one of the most simple and at the same time most effective machines for this purpose which has ever been before the public.

BANBURY ONION AND VEGETABLE SHOW.

BANBURY has long been celebrated for its magnificent Onion competitions, but the display of Thursday, Sept. 14th, eclipsed all previous shows of Onions held at that place, or probably elsewhere. This is not to be wondered at when such redoubtable champions as Messrs. Wilkins, Pope, Waite, Kneller, Lye, Doherty, and Posse marshalled their fullest strength in the struggle for supremacy and the extremely liberal prizes offered.

The present series of shows was instituted by the late Mr. Henry Deverill with a view to encourage the better cultivation of this most wholesome esculent. But, alas! the originator was not spared to see this most interesting Exhibition and the immense results of bis enterprising handiwork, and many were the sympathetic regrets expressed by those present on the occasion. Fortunately, the institution is not likely to suffer, for the enthusiasm is still continued by the widow, Mrs. Deverill, and her enterprising manager, Mr. Crews. The competition was large and very severe, but Mr. Wilkins, gardener to Lady Theodore Guest, Inwood House, proved invincible in the principal Onion classes, although he had to lower his flag to Mr. Pope, gardener to Earl Carnarvon, Highelere, in the class for eight distinct kinds of vegetables.

In class 1, a gold medal or timepiece was offered for the largest and handsomest specimen of any one kind of Deverill's Pedigree Onions, and here Mr. Wilkins staged six bulbs of Lord Keeper, perfect in shape and quality, which turned the scale at 15 lbs. Mr. Lye, gardener to W. A. Kingsmill, Esq., Sydmonton Court, closely followed with six splendid bulbs of Ailsa Craig weighing $13\frac{3}{4}$ lbs.

Class 2 was for twelve specimens of pedigree Onions, and here again Mr. Wılkins was successful with Ailsa Craig, scaling 26½ lbs. Mr. Pope was second with the same variety weighing 22 lbs.; third, Mr. Kneller. Sixteen competitors, all showing well.

Class 3, for twelve specimens, enumerated kinds, Mr. Wilkins leading with Anglo-Spanish weighing $20\frac{1}{2}$ lbs., perfect in every respect. Second, Mr. Waite, gardener to Colonel Talbot, Glenhurst, same kind, weighing $18\frac{1}{4}$ lbs. Third, Mr. Pope, with Royal Jubilee weighing $18\frac{3}{4}$ lbs. Thirteen competitors, and the competition very close.

Class 4 was for twelve specimens of that splendid keeping Onion, Improved Wroxtor, Mr. Kneller having the best, weighing 14\frac{3}{4} lbs., followed by Mr. Wilkins, whose bulbs were slightly heavier (15 lbs.), but less perfect in finish. Third, Mr. Pease.

Class 5, was for twenty specimens of any kind, open only to cottagers,

mechanics, and allotment holders. Weight of bulbs 30½ lbs., 30½ lbs.,

-Eight distinct kinds of vegetables. First, Mr. Pope, with a faultless collection, containing grand samples of Exhibition Carrots, Lyon Lecks, Glenhurst Favourite Tomatoes, Middleton Park Beet, Aylesbury Prize Celery, Autumn Giant Cauliflower, Ailsa Craig Onions, and Satisfaction Potatoes. The second prize went to Mr. Wilkins, who

had similar kinds, but a few points short. Mr. Waite was a close third. There were five competitors, all good.—W. CRUMP.

MANCHESTER.—SEPTEMBER 15TH AND 16TH.

In the Gardens at Old Trafford the Royal Botanical and Horticultural Society of Manchester held a very fine Exhibition of fruit and other produce on the above dates. The beautiful gardens, containing so many well grown plants, all showing the touch of a master hand, add greatly to the interest of the meeting, which, combined with fine weather, excellent music, and easy access to the public, caused a crowded

attendance.

For twelve dishes of fruit the Earl of Harrington, Elvaston Castle, Derby (gardener, Mr. Goodacre), was first with fine Muscat of Alexandria, Black Alicante, and Gros Guillaume Grapes, a beautiful Countess Melon, very fine Sea Eagle and Golden Eagle Peaches, two good Pines, well coloured Nectarines, Louise Bonne de Jersey Pears, Cox's Orange Apples, and fine Figs and Plums. Sir J. M. Pease, Hutton Hall (gardener, Mr. McIndoe), was second with a fine collection. Unfortunately, some of his Grapes were rubbed in transit. The Duke of Newcastle (gardener, Mr. Slade), was third. For twelve bunches of Grapes, in not less than three varieties, two gold and one silver medal were offered, causing keen competition. E. M. Mundy, Esq., Shipley Hall, Derby, was first with a fine heavy Gros Guillaume, Muscat of Alexandria, and Gros Colman, all showing skilful treatment and good finish. The Earl of Harrington was second with a little smaller examples of high merit, having Gros Maroc, Aln wick Seedling, and Madresfield Court, in addition to the varieties staged in the first prize collection. The Duke of Newcastle was third with good heavy bunches. For six bunches of white Grapes E. M. Mundy, Esq., was an easy first with large, well coloured bunches of Muscat of Alexandria. Second, the Earl of Harrington with excellent Bowood Muscats, Muscat of Alexandria, and Mrs. Pearson. The prizes in this class were given by Mr. W. Innes of Derby. For four bunches of black Grapes Mr. W. Innes, Derby, was first with enormous clusters of Gros Guillaume, which had suffered somewhat in travelling. C. Lee Campbell, Esq., Glewston Court (gardener, Mr. S. T. Wright), was second with Black Alicante, firm in bunch and in perfect condition. The Earl of Harrington was third.

With eight dishes of Apples the Earl of Harrington was first, showing large, highly coloured fruit of Loddington, Flower of Kent, Gloria Mundi, Peasgood's Nonesuch, Ribston Pippin, Adams' Pearmain, Fearn's Pippin, and Cox's Orange Pippin. Sir J. M. Pease was second with fruit grown under glass. Mrs. Barlow was third. A special prize was awarded to C. Lee Campbell, Esq., whose dessert Apples were very fine indeed. For eight dishes of Pears the Earl of Harrington was first with large family of Pitmesten Duchers, Catillag, Dergand du Comise. with large fruits of Pitmaston Duchess, Catillac, Doyenné du Comice, Duchesse d'Angoulême, Beacon, Beurré Diel, Williams' Bon Chrêtien, and Louise Bonne de Jersey. Sir J. M. Pease was second, and Mrs. Barlow third. With twelve Tomatoes Mr. James Mason, Victoria Street, Manchester, took leading honours, followed by J. Grant Morris, Esq., Allerton Priory, and Mrs. Lord, Oakleigh, Ashton-on-Mersey. In the Apple and Pear classes open to residents within twenty miles of Manchester, the competition was good, and the fruit fine for the district; the most successful exhibitors being J. Watts, Esq., R. R. Gills, Esq., J. J. Travis, Esq., A. Hornby Lewis, Esq., and the Earl of

Messrs. J. Peed & Sons, Norwood, staged about 120 dishes of Apples and Pears, also a collection of Grapes, altogether a fine collection, which deserved the gold medal awarded. Special prizes were awarded as follows:—To the Duke of Newcastle for six grand Pines; to Mrs. Barlow for 100 dishes of Apples, Pears, and Crabs; to Messrs. Keynes and Williams, Salisbury, for a most imposing and beautiful display of Dahlias, arranged in a charming manner; and to Messrs. Harkness and Sons for a magnificent collection of hardy cut flowers in over eighty Mr. H. Merryweather, Southwell, Notts, also had a special varieties. prize awarded for thirty-seven dishes of Bramley's Seedling Apple, very fine. Other non-competing exhibits were staged by Messrs. Dickson and Robinson, Old Mill Gate, Manchester, who put up fine Roses and Gladiolus; Messrs. Dickson, Brown, & Tait staged good Dahlias and Gladiolus; Messrs. Caldwell & Son, Knutsford, had Apples and Dahlias; and Miss Hopkins, Mere Cottage, Knutsford, hardy flowers and Pansies.

TRADE CATALOGUES RECEIVED.

Fred Horsman & Co., Colchester.—Orchid Specialities.

G. Mount, Canterbury.—Roses.

McRonald, Chichester.—Dutch Bulbs and Flower Roots.

Van Zinten & Nieuwerf, Boskoop, Holland, and Tottenham, N.—Plants for Potting and Forcing.

T. S. Ware, Hale Farm Nurseries, Tottenham .- Carnations and Picotees and Autumn Bulb Guides.

Dicksons, Limited, The Nurseries, Chester .- Select Roses.

FRUIT FORCING.

Figs.—Early-forced Trees in Pots.—As it is not advisable to increase the pot room, a few inches of soil may be removed from the base of each ball, cutting back the roots, also reduce the ball a little at the side so as to provide room for fresh compost, and remove the loose surface soil, cutting off any strong straggling roots. The drainage must be thorough, using a compost of fibrous loam three parts, decayed manure one part, and old mortar rubbish pounded one part, thoroughly incorporated and had under cover a few weeks previous to potting (if necessary) to become moderately dry. Make the whole very firm. Afford a good watering, and place the trees where they can have plenty of air with shelter from heavy rains and snow. This is only available for trees that are not in large pots or have the roots mainly restricted to the pots, as those that are in 18-inch pots and have been stood on brick pedestals to prevent their sinking with the fermenting material, require different treatment. In their case every particle of the old Oak or Beech leaves should be removed from the bed, and the surface dressings also be picked from amongst the roots with a handfork, shortening the strongest roots. The drainage being attended to the trees are to be placed in position on the loose brick pedestals, and the soil surface-dressed with the compost named firmly rammed into the pot. Supply water to settle the soil, and after this keep the house cool, dry, and well ventilated until the time of starting in November or early December. This method is preferable to repotting annually, as the trees are less likely to cast their first cropof fruit, which is the most important, and it is not advisable to disturb trees in 18 or 20-inch pots at the roots more than can be helped. Trees that are not in as large pots as desired, or when it is thought desirable to increase the root space, a liberal shift may be given, the sides of the ball being loosened with a handfork, and any straggling roots cut back, also the matted roots in the drainage. Provide good drainage, using the same kind of compost for potting as previously advised, and ram it as hard as the ball, this having been moistened previously, but the soil used in potting must be rather dry.

Succession Houses.-The trees now ripening the second crop Figs must be gradually kept drier as the days shorten, a little fire heat being necessary in dull weather to admit a free circulation of air and prevent damp, for moisture settling on the fruit causes it to fall an easy prey to fungi, which compass its decay. Particular attention must be given to the exposure of the wood to the full influence of sun and air, removing all useless growth, thinning where the shoots are too close, and allow the points to stand well up or out to the glass. As already mentioned, the supplies of water must be diminished, but not so as to cause the foliage to become limp, and it may be withheld from borders that have been well watered and mulched up to the middle of this month. The main point is to get the wood well ripened, especially at the points of

the shoots.

Lifting Over-luxuriant Fig Trees.-When in rich borders and the rootage deep and extensive, Fig trees are apt to become too strong for fruit bearing, and in that case preparation should be made for lifting them as soon as the leaves turn yellow. If the trees are fruitless a trench should be taken out about one-third the distance from the stem the branches extend, cutting off all the roots. This will check the tendency to late growth and concentrate the forces on the ripening of the wood. In other cases the trees should be attended to as soon as the crop is gathered, lifting them with care, cutting back all long roots, reserving the fibres only. Good drainage with a drain to carry off superfluous water is necessary. A 3-inch drain with proper fall and outlet will do the last, and a foot thickness of brickbats with a 3-inch layer of old mortar rubbish over will provide the first. A border of 4 to 6 feet width is much better than a wide one, and 18 inches to 2 feet depth of soil ample. What is wanted is firm, sweet, calcareous soil that will admit of the percolation of water and air through and retain the manurial elements essential to the production of fine fruit. Good turfy loam four parts, and one part each old mortar rubbish and road scrapings forms a suitable and durable border, incorporating well. Place the compost together firmly so as to insure a sturdy short-jointed growth. Spread out the tree roots evenly, work in the soil amongst them, and make it firm, placing them in layers as they rise, and keeping them well up. not covering the topmost more than 2 or 3 inches. The soil must be moist when used, but it ought not to be wet. Give a moderate watering, and keep cool and dry.

Peaches and Nectarines .- Trees Ripening the Fruit in July .-The trees will now be approaching the resting period, indicated by some of the leaves falling. They should be kept somewhat drier at the roots, but if the lights have been removed the trees will not take any harm, but be benefited by the thorough moistening of the soil, as they will have a correspondingly cool atmosphere and not be excited by fits and starts as in houses that are made receptacles for plants. If the trees, however, are very strong, it is not wise to remove the roof lights, and if the wood does not ripen well a trench may be made at a distance of about one-third the height of the tree from the stem, and detach all roots down to the drainage, leaving the trench open for a fortnight, when it may be filled again and made firm. This will cause the wood to harden, and the sap will be concentrated on the buds and help to plump them. Young trees only will require this; but older trees that have the wood very strong should be root-pruned, and have the roots wholly or partially lifted before the leaves have all fallen. In the case of weakly trees remove the old soil from over and amongst the roots, supplying fresh, rather strong calcareous loam, making it firm, following with a good soaking of liquid manure.

Trees Ripening the Fruit in August and Early September .- Cut out the wood that has borne fruit, leaving no more successional shoots than are necessary for next year's crop and that can be fully exposed to light. Cleanse the foliage of dust and red spider by water directed with force from a garden engine or syringe, and repeat occasionally. If there is scale promptly apply an insecticide, petroleum emulsion being one of the most effective, also against red spider, a soapy solution destroying it, and for brown aphis use tobacco powder or juice. There must not be any lack of moisture at the roots, therefore apply water to the inside borders as necessary to keep them from becoming too dry. Afford abundant ventilation, and if the wood is not ripening well keep the house rather warm by day, and throw the ventilators open at night, but a warm, close, moist atmosphere must be avoided, as that would be injurious than otherwise.

Late Trees.—As the fruit is cleared from the trees the shoots that have borne fruit should be cut to a successional one at the base, and where the growths are too crowded they must be thinned. This with free ventilation and gentle fire heat in cold localities during dull weather, and with the growth strong will assist in ripening the wood. This is of primary importance as regards next year's crop. The trees must not lack moisture, and yet a drier condition is advisable whilst the fruit is ripening. Some soft netting suspended beneath the trees will be useful to save any fallen fruit, but it must be looped up in small pockets to prevent the fruit bruising each other. With an examination of the fruit in the morning and late afternoon there is no necessity for the netting. The fruit is better gathered before becoming dead ripe, yet not before it parts readily from the branch, and kept in a cool, light, airy fruit room until required.

Melons.—While the fruits are swelling water must be supplied, keeping the soil healthfully moist, and feeding with tepid liquid manure. A moderate moisture also must be maintained by damping in the morning and in the afternoon, and at closing time a light syringing of the foliage may be practised if the weather be bright. Remove all superfluous growths as they appear, and admit air early or at 75°, keeping the bottom heat steady at about 80°. Maintain a night temperature of 65° to 70°, 70° to 75° by day, and 80° to 90° with sun heat, closing sufficiently early to increase to 95° or more.

A little fire heat so as to insure a circulation of air constantly and prevent the deposition of moisture on the fruit, and no more water at the roots than is necessary to prevent flagging, will accelerate the ripening and do much to improve the flavour. In manure-heated pits and frames no water will be required where the soil has been kept properly moist during the swelling of the fruit, but keep the sides well lined, and leave a little air on at the back at night. The fruit should be raised well above the surface of the bed. Any fruit wished to be kept for a time should be cut with a portion of stem when it gives indications of ripening, placing in a dry airy room; if wanted ripe place in a warm house in the full sun, where it will ripen better than in cool frames.

THE KITCHEN GARDEN.

Open-air Mushroom Beds.—This has been a rather trying season for early formed Mushroom beds, and unless there is sufficient moisture in the manure to insure its steady decay there is no heat to promote the rapid spread of the spawn or to hasten the growth of Mushrooms. Any beds spawned early in August ought now to be examined. If there are no signs of Mushrooms, the manure also being found very dry below the surface, then the attempt should be made to moisten it by either exposing to a soaking rain or else form holes all over the bed, and then give two or three waterings with a rose on the pot, using tepid water. This must not be overdone, though judging from the present state of the beds there is little likelihood of saturation taking place. After the beds have been moistened cover heavily with strawy litter. Those found to be in a fairly moist state when first examined need not be watered. Mushrooms ought to be forthcoming in from five weeks to six weeks

Successional Beds.—Some of the most profitable beds are those that are formed and spawned during the month of September. Open air beds must be ridge-shaped, but may be of any length, or, say, from 6 feet upwards. The site should be well drained, somewhat sheltered, and if it can be managed the beds ought to be formed where neither moles nor large field mice are likely to get at them. Horse droppings without a portion of straw, to the extent, say, of one-third of the bulk, are unsuitable for ridge-shaped beds. The heap must be well prepared or it will heat very violently, or so much so as to quite spoil the bed after it is put together. About a fortnight should be taken up in preparing the manure, the heap being turned inside out every second or at the most third day, and watered whenever found dry. Dry manure is worthless for making into Mushroom beds, and the watering will in many cases be necessary according as the materials are finally put together. Properly prepared manure must be free from rank put together. Properly prepared manure must be free from rank smells and violent heat, but still be capable of going on heating and decaying.

Forming and Spawning.—Mark or stake out the site, allowing a width not exceeding 3 feet, and work just inside of this. Shake out the manure so as to separate what flakes there may be and distribute it in layers, either trampling or heavily beating down each layer with the back of the fork. Gradually narrow the ridge till when from 30 inches to 3 feet high, it is only 6 inches wide. Finish off neatly, and slightly round the top. The manure must be put together so firmly as to make it no easy matter to thrust the necessary trial stakes well into the bed. Examine these sticks frequently. At first the heat will most likely increase considerably, but directly it is on the decline, or as soon as the heated part of the trial sticks can be comfortably borne in the

palm of the hand, the time has arrived for spawning.

Use fresh spawn and break the bricks up into about eight pieces. Insert these lumps in holes formed with the hand, and not a dibble, just below the surface, and about 8 inches apart each way, angling the holes being advisable. The start should be made 6 inches or so from the ground, and there will be no necessity to spawn quite up to the top of the ridge. Make all level and firm, looseness being prejudicial to the spread of Mushroom spawn. Continue to frequently examine the trial sticks, and if they are found to be very hot to the hand Continue to frequently examine the some of the enclosed vapour must be let out by means of a pointed iron rod thrust down through the centre or ridge of the bed at short intervals. This will quickly lower the temperature and save the manure from becoming dry and musty. A little judgment must be exercised as to when to soil over the beds. If the manure has been well prepared, the proper time to case over is on the fourth day after spawning, but it is better to defer this a few days longer rather than cause over-heating. Fresh fine yellow loam suits Mushrooms well, nothing answering better than that obtained from immediately under turf in a meadow. Failing virgin loam use garden soil dug from between the top spit and subsoil. Firmly cover the beds with a layer 2 inches thick of soil, but do not wet and plaster it on, or cracking to a most injurious extent will inevitably result. Protect open air beds with strawy litter, lightly at first, and heavily, in the form of a thatch, when either heavy rains or frosts have to be warded off.

Mushroom Beds under Cover.—Now is a good time to form beds either in Mushroom houses proper or in cellars, sheds, or snug outhouses of any kind. These beds should be nearly or quite flat, a gentle slope to the front being usually given, of any convenient width, and from 12 inches to 15 inches in depth. They can be enclosed either by walls or stout boards kept in position by means of strong uprights, and preferably be formed on the floor, shelves answering better later on. these cases rather less short stained straw ought to be left with the manure, though in all other respects the preparation should be the same. This season much green food has been given to horses, but it should be remembered that it is from horses in hard work, and fed on hay and corn, that the droppings most suitable for making into Mushroom beds are obtained. If there is no choice take every care with the best that can be had. No fire heat ought to be turned on for some time to come, the best crops very frequently being had from the beds in snug unheated sheds and cellars. Prepare more manure for successional beds, supplementing it with Oak leaves if the bulk is insufficient. Old Cucumber and Melon beds in houses might also be spawned with every prospect of a good crop of Mushrooms following in due course if only the top heat is not too strong.

APIARIAN NOTES.

HOME FROM THE MOORS.

AFTER two months of suspense and toil, with alternate disappointments and successes, we have returned from the moors. We had a brief period of fine weather, but this was followed by torrents of rain and a low temperature, and there were few mornings without hoarfrost. With all these drawbacks, however, I am home with a fair yield of Heather honey, but by no means so great as I have frequently had from the same place in as few days. My best hive, a second cross Carniolan, weighs gross 160 lbs., having increased in weight 70 lbs. My next best, a second cross Syrian, weighs about the same. Both these, along with the others, lost in weight the first month from 12 to 20 lbs., and near the end another 10 to 12 lbs., as is always the case, so that the actual gathering of our best hives would be 100 lbs. The average weight gathering of our best hives would be 100 lbs. The average made from the setting down till the lifting is about 40 lbs.

A dozen hives increased before going to the Heather to thirty-four. Although constantly attending my bees at the Heather, six swarms left unseen and were lost, it being impossible to detect them. Twenty seven of the thirty-three swarms I had were all returned. Among the rest was a Punic nucleus, the pure and cross giving alike satisfaction, having made on the whole as much, or perhaps more, than any other variety. They are no worse than other bees, nor so bad as the pure Italians for stinging or robbing, but are not entirely innocent in that respect. They are very prolific, and it is this good quality that our modernists do not know how to put to

the best use for large yields of honey. The toil from excessive swarming this season is due entirely to practising contrary to what I teach, and, like many more, have suffered accordingly. Influenced by persuasion and past bad seasons I wrought my hives with two divisions instead of three, as I have advised sensible bee-keepers to do.

I am perhaps prejudiced against the mild tempered pure Carniolan free from the yellow bands, but I cannot help admiring the beautiful whiteness of their honeycombs. I thought till early in the summer that I possessed the original pure strain first sent me by the late Mr. Alfred Neighbour nearly twenty years ago, but somehow, through so much swarming and so many queens about, every one was lost, so I have begun anew with one that I have safely introduced lately. Having taken some trouble to obtain the pure strain free from Italian and Syrian blood, I shall if spared till another year take care to increase and to keep them pure, having a good opportunity of doing so.

Elvanfoot has about fifty inhabitants, and it is becoming well known as a healthy locality. Among the inhabitants is one who dislikes bees and bee-keepers. He says, "Bee-keepers bring wet weather, and the bees take the strength out of the grass and the Heather." The person alluded to has for years tried to prevent bees being set upon neighbouring farms, and this year appealed to the factor of an adjoining estate to compel the bees to be removed. This was, however, only partially complied with, the owners of the bees removing them several hundred yards.

As everything by way of reading and correspondence are in arrears, I will in the next issue answer several queries, and commence a series of practical articles for beginners and the inexperienced. I have omitted to say that my best hive mentioned above is an old stock that swarmed in June, the prime swarm from it being nearly as heavy, and gave a surplus of honey early in the season. Your readers can now judge of the reliability, or unreliability, of the saying, "When hives swarm there is an end to honey gathering." In my future articles I will give full instructions how to be as successful as—A LANARKSHIRE BEE-KEEPER.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Secretary, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.— Secretary, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—Secretary, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cow and Pig Manure Water for Chrysanthemums (MacLeod).—There is no safer liquid stimulant than that made from cow manure provided it is scalded with boiling water so as to destroy destructive larvæ before adding the water—say twenty gallons to one peck of the manure, stirring well and leaving a day or two. If you mean the drainings from the cow house it is an excellent manure, and should be diluted with about a fourth of water when neat; if from the manure as well it should be diluted to the colour of mild beer. Piggery drainings are much more powerful than either stable or cow house drainings, and could only be safe when diluted with ten times the bulk of water. Nitrate of soda may be used occasionally, but not too often, at the rate of a \(\frac{1}{4} \) oz. per gallon of water.

Phygelius capensis (L., Dundee).—You ask whether this is a shrubby or herbaceous plant. According to the "Botanical Magazine" it is both. The description in connection with a beautiful coloured illustration, tab. 4881, vol. xi., third series, states the plant is "shrubby below and herbaceous above." That is its general character. In the south the lower part assumes a shrubby habit and retains it through the winter, the Pentstemon-like stems of scarlet flowers dying and cut back to the sound parts. In some colder localities we are told the plants die down the same as Fuchsias do in the open ground and produce young growths from the rootstock annually. Only in such instances could the plant be popularly described as herbaceous.

Storing Fruit (F. J.).—There is nothing better than clean white paper for the fruit to rest on, though it is not necessary unless the wood is likely to taint the fruit. Cocoa-nut fibre would certainly form a better "bed" for the fruit; but choice fruit should have as much of its surface exposed as possible, so that it might ripen equally in every part. As this process begins at the eye, that part is generally placed downwards, in some cases embedded in sand or other material to secure equal ripeness all over. To insure the fruit keeping sound as long as possible it is often packed in material calculated to exclude air, and maintain a uniform temperature without tainting the fruit. Peat moss litter has been used for storing Apples in with complete success, and the fruit was not in the least tainted. The same variety kept longer in it than by any other method, and fetched more money. The moss litter was of course sweet. The very soft wood wool referred to on page 220, September 7th, is excellent as a packing for fruit.

Bones and Kainit for Fruit Trees (T. W. F.).—If it is desired to get as much value out of the bones as possible the first year, they should be dissolved—that is, made into superphosphate. Steamed bone meal is a little more durable, but by no means to be considered a permanent improvement. Crushed bones have value extending over several years, and ought not to be used where the trees are in immediate want of support, it being better to employ bone superphosphate, so as to secure the best results in the summer following its application. The superphosphate and kainit should be in a mixture of equal proportions, and spread over the ground under the branches of the bushes or trees and for a foot beyond in the autumn, at the rate of 2 ozs. per square yard, or $3\frac{3}{4}$ lbs. per rod ($30\frac{1}{4}$ square yards). The ground may then be lightly pointed over, but not injuring the roots, and left until the spring. If a full crop of fruit needs support give a supplementary dressing of powdered nitrate of soda—say $1\frac{1}{2}$ lb. per rod, a little more if the soil is of a dry nature, or a little less if the ground be damp.

Pear Tree Blister Moth (G. T. D.).—The moth is minute and active, body satiny white, the wings having an orange ground spotted with black and other colours. It appears in May, and after pairing the female deposits her eggs at the end of that month or beginning of June, or later, in the tissue of the leaves on the upper surface, and from these issue the grubs or caterpillars, which feed beneath the epidermis, and produce dark brown blisters, corresponding to the spread of the caterpillar. Sometimes the blisters run together. When the caterpillar is full fed, which usually takes place in August or September, it eats its way out, and entering a crevice in the bark or a wall, where it will be snug and dry, it spins a white silken cocoon, very beautiful, and becomes a chrysalis inside, being quite small in itself, but easily recognisable by the silvery coating. From this it appears as the moth at the time before named. Those at the back of the old plaster are the cocoons—some empty, others contain chrysalids. The description to which you allude is not accurate as regards this country, but it is strictly so in respect of warmer and drier climes.

Housing Chrysanthemums (A. Pitman).—Mr. Molyneux's references on page 73 of his work, which you have found so useful, apply to late varieties generally as the first to be placed under glass with the object of advancing the blooms so that they may be ready for cutting at the same time as the earlier varieties, the plants of which are housed later. There are only about two in your list that can be called late or slow in opening, Hero of Stoke Newington and Barbara. Endeavours to have all the varieties in condition at the same time are only as a rule resorted to by exhibitors, and growers of Chrysanthemums for house decoration find a prolonged display the most satisfactory, therefore they prefer to allow the different varieties to open at their natural time. Judging from the names in your list you do not intend the blooms for exhibition, and therefore you will not err by housing all the plants at the end of the present month, sooner if the nights are clear and frost appears immiuent, though if you wish to advance any particular varieties place the plants under glass at once. Some of the names in your list are not to be found in the National Chrysanthemum Society's catalogue, and others are misspelt. Chrysanthemums are often injured by a keen frost at the end of September or early in October, mild weather supervening, and growers should be on the alert accordingly.

Odontoglossums Planted Out—Orchids from Seed (J. Wilson).
—Odontoglossums are planted in thousands by Mr. F. Sander, in his establishment at St. Albans. A layer of open material, consisting of sphagnum, fibrous turf and charcoal, is spread over ample drainage on side stages, and the plants established in it. Under the skilful treatment to which they are subjected they grow as well as plants can grow, and lift well for establishing in pots. The thickness of the compost varies according to the size of the plants, but the same depth as that

usually found in pots for different sized plants is a safe rule of guidance. Planting out is a labour-saving process in watering—a point of greater importance in extensive trade collections than in private establishments. The atmospheric conditions of the houses are specially appropriate for the well-being of the plants. The best way of raising Orchids from seed is to sow all that is found in the pods as resulting from careful fertilisation. To attempt to separate the weak from the strong grains, as revealed by a powerful magnifying glass, would be somewhat too tedious. The seed is cast on the sphagnum round established plants, and if good, and the essential conditions of moisture and temperature maintained, germination follows in due course. The most careful skilled attention is needed, transplanting and establishing the seedlings being an extremely delicate process. The plants flower in from ten to fifteen years after sowing the seed, the majority being no better than the parents, perhaps worse. Raising Orchids from seed reminds us of digging for diamonds—an enormous amount of rubbish has to be removed, but now and then a gem of the first water is found, the lucky owner rejoicing accordingly in the reward for his enterprize and perseverance; but many diamond searchers are not lucky, and it is the same with Orchid raisers, and experts have the best chances of success

Sirex gigas (A Young Entomologist).—The Sirex gigas is found in the north of Europe; it has been taken in England, but very rarely; it is a British species, and is sometimes taken in Scotland. It is likely to be met with in Pine forests, as the female seems to prefer that wood to deposit her eggs in. The male is considerably smaller than the female, and has no sting. The sting of the female consists of three parts—a sheath which divides into two parts or valves, and a fine instrument somewhat resembling a needle; it is with this instrument it wounds its enemies, and the sting is said to cause excruciating pain. The microscope discovers this part to be beset with a number of very minute teeth, like the edge of a saw; with this sting the creature can pierce the wood of sound trees; for we suspect it does not always deposit its eggs in such as are decayed, but rather in such as will supply the larva with nourishment when it is hatched. The eggs are laid in clusters of 200 or 300 together; they are of a pale yellow colour, about the thirtieth part of an inch in length, and shaped like a weaver's shuttle. The larva lives in the body of the tree, enlarging its habitation as it increases in size, for it never leaves the tree till it becomes a winged creature. The larva when full grown is about 14 inch in length, and as thick as a goose quill. It is a heavy sluggish creature, almost cylindrical, the head very small, and the whole of an uniform pellucid yellowish colour. It has a small spine at the end of the body like those by which the larva of some spinges are distinguished; this spine is also a striking character in the perfect Sirex. In the pupa the form of the winged creature is more visible than in the larva state; it is of a browner colour than the larva, and the rudiment of the sting and legs are very visible.

Naming Fruits—A Roundabout Procedure.—A correspondent informs us that he usually sends his Pear problems to a friend, and if neither he nor his man can name the fruit, it is at once sent by the friend to this office. Our correspondent further states that he does not wish to trouble his friend at present, so sends fruit direct to us, with a request that we send the names by post. This is an improvement on the roundabout way, but we only name fruit through these columns for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules.

Names of Fruits.—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (E. M.).—The clustered fruits are varieties of the Siberian Crab, the smaller form with narrow leaves being Pyrus Malus prunifolia, and the other P. M. baccata. You are probably right in the names of the Apples. (J. C. M.).—We cannot name the Apples. The larger ones are essentially faulty, and the others not worthy of names or cultivation. (J. E.).—1, Probably Golden Reinctte, but not sufficiently matured for positive identification; 2, Dr. Harvey. The Pears were unripe and in a condition which rendered naming them an impossibility. (D. M.).—1, Souvenir du Congrès; 2. Williams' Bon Chrêtien; 3, Immature; 4, Probably Beurré de Capiaumont, and certainly not Van Mons Léon Leclerc. The Apple is Five-crowned Pippin. (H. T. H.).—1 and 5, Gathered before ready, consequently unrecognisable; 2, Mère de Ménage; 3, Wyken Pippin; 4, Small fruit of Lane's Prince Albert. (B. W.).—12, Cobbam, a good Apple; 14, Dumelow's Crab. The others cannot be named; they are probably local kinds, and we do not wish to see any more of them. The Crab was quite rotten. If your object is to grow fruit for sale increase the varieties which thrive best in your s

but the stalk end containing the most characteristic feature of the variety was quite rotten; 2, Beurré d'Amanlis. (G. J.).—1, Cox's Pomona; 2, Kirke's Fame; 3, Northern Greening; 4, Nonesuch; 5, Sturmer Pippin; 6, probably a small fruit of Court Pendû Plat. (H. C.).—1, Bergamotte Dussart, a Belgian Pear; 2, Duchesse d'Angoulême; 3, Summer Thorn. (F. B.).—1, 2, and 5, not known, no stalks to assist in the identification of the fruits; 3, Mère de Ménage; 4, Cellini; 6, probably Loddington Seedling, but no stalk. (J. E. S.).—1, Cellini. The others cannot be named, not being well grown specimens, and all of them have been dragged from the trees too soon. (G. G. P.).—Winter Hawthornden. (H. H.)—Apple Ribston Pippin, Pear Autumn Bergamot. (J. D.).—1, Beauty of Kent; 2, probably local, resembles Tower of Glamis; 3, Beauty of Hants. (Knebba).—1, Hollandbury; 2, the two specimens are very unlike, but bear a general resemblance to Dutch Mignonne; 3 and 4, not known, probably local. The Pears were hard, and not ready for naming. Hard Pears.—We have several boxes of Pears that it is quite impossible for anyone to name with any approach to accuracy. They have been sent weeks, and some of them months, too soon for the purpose in question.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (James Boyd).—We regret that the plant which you have taken such creditable pains to describe cannot be identified from the leaves, though special endeavours have been made to determine its name. (H. C. L.).—Funkia grandiflora. (L. M. B.).—Odontoglossum crispum. (H. J.)—Brassia Lawrenceana. (D. H.).—1, Clematis coccinea; 2, We kept the spray of this in water to enable the buds to open which they failed to do, without blooms it cannot be identified; 3, Colutea arborescens; 4, Ceanothus azureus; 5, An Azalea, but must have flowers; 6, Tropæolum speciosum. (C. E. B. B.).—Specimen insufficient, probably Tropæolum Ball of Fire. (R. A. C.).—1, Flowers shaken off; most likely Pelargonium Scarlet Unique; 2, P. quercifolium; 3, Helenium pumilum.

COVENT GARDEN MARKET .- SEPTEMBER 20TH.

Market quiet; prices remaining the same with exception of Cobs, which are finding their level at a slight reduction.

POOR MILK.

HITHERTO it has been laid down by authorities that quality in milk fluctuates 3 or 4 per cent.; it is also admitted that the milk of a "stale" cow is less rich by 5 per cent. than that of a "fresh" cow-a "stale" cow meaning one that has been so long in milk after calving that there is a falling off in both milk yield and richness; a "fresh" cow, one that has recently calved. This has formed a basis for analyses made in the interest of the consumer. It has been regarded as a safe guide, a higher per-centage of poverty in quality being invariably taken to indicate just so much added water. Having regard to the simplicity of milk adulteration, and to the temptation which a farmer struggling with adversity has to indulge in it, it is only right that some check in the guise of a fair test should be kept upon it. It is equally right that the producer should have fair play, and therefore it is all important that the scrutiny should be just and thorough.

A case recently tried in the Marylebone Police Court so clearly points to the possibility of erroneous analyses, that it is worthy of special notice. The report says that two summonses came before the Court, issued at the instance of the Hampstead Vestry, against a dairy farmer named Robert G. Norman of Hillfield Farm Dairy, Bushey, Herts, for sending milk to London which on analysis was alleged to have been adulterated by the admixture of 6 and 7 per cent. of water respectively. The sanitary inspector took samples of the milk on its arrival at the Kilburn Railway Station on August 11th and 12th. Professor Stokes analysed the samples, and certified them to contain 6 and 7 per cent. of added water. The West London Dairy Company, to whom the milk was consigned, also had it tested by Mr. Lloyd, the analyst, who certified it to contain as much as 9 per cent. of added water. Both certificates were met by Mr. Norman with the plain answer that the milk was in the same condition as taken from the cow, and luckily for him it was arranged that Mr. Lloyd should see the cows milked, and make an analysis of that milk. He saw the seventeen cows milked in the middle of a field. All the milk was put into a large churn, and he took a sample. The result of his analysis showed 8 per cent. of added water.

Mr. Lloyd said he believed the only explanation to be given was the exceptionally hot and dry season this year, and its effect upon the cows. The dry season had so affected the food as to alter the composition of the milk. The poorness of the food would affect the quality of the milk and diminish the solids. It was not the dryness of the food eaten that changed the quality of the milk, but the nutriment obtained out of it by the cow. The quantity of water drank by the cow was not important. In dismissing the summonses, Mr. Plowden, the magistrate, said the substantial question underlying all such summonses was whether or not there had been fraud-that must be proved by cogent evidence, for it was a serious matter for an honourable and respectable man to be convicted of such an offence. Mr. Lloyd's analysis must be taken as a perfectly honest one, and it showed that due allowance had not been made for the very hot weather and dry season.

We have quoted this important case in sufficient detail to make it quite clear, because it demanded something more than a mere passing notice. We have long held that if some such scheme of Government supervision of dairy farms in force in Denmark were possible with us, it would be for the mutual

benefit of producer and consumer. "Honourable and respectable" men would then not only have the protection of a skilful Government inspector, but they would also receive invaluable advice and guidance in the provision of food, and the best method of using it for the cows. To have a full flow of rich milk we must feed aright, under a sound method of food production as well as of its use. Had dairy farmers generally such a method entering into the economy of farm management, they would have come through the great drought with comparative ease. There would have been little if any shortness of food supply or deterioration of milk quality. It may seem hard—almost cruel -to say this to men struggling with adversity; but surely it must be granted that he is their true friend who, knowing how many of them might do so much better, strives to assist them in doing it.

WORK ON THE HOME FARM.

Couch fires are burning everywhere wherever we go; they are a sign and token of the doing of much good work, the autumn to get the land clean. Twenty-four of them did we see in one field in Yorkshire a few evenings ago. The following day we came upon a long line of them on a south country farm, and it was delightful to see the men doing their utmost to keep the fires going and to set fire to other heaps. If ever we are to have clean land it is surely now after six months of summer followed by another month of fine weather. Autumn tillage, too, is being done far more generally than usual; we were much pleased recently to see furnace ash being carted upon a Midland farm to be ploughed into the heavy land. Such signs of sound energetic action make us hopeful for the future of farming.

The Wheat sowing is in hand, also Rye and Winter Oats. Wheat should be sown only on deep sound loam; it, with the other crops mentioned, should be got in now without loss of time. Where new layers of mixed seeds or Rye Grass are wanted, it is a good plan to sow now soon after the Wheat is in, because a full plant seldom fails from an autumn sowing; but sowing with spring corn is always much more speculative, as many a farmer has found to his cost this year. Vetches should also be sown soon; a second sowing early in October is also worth while as a connecting link between the first sowing and spring crops. Frosts in Derbyshire dales have touched some vegetation; they are a reminder to push on, using green Maize, holding in hand crops less susceptible to frost. Cows will eat Maize after frost has turned the tops of the plants brown, but it is not so nutritious then. Mention is made of this because we have already seen sheepfolds on roots. The only roots that should be in folds yet are early sown White Turnips; all other root crops should be held over for winter. Dale farmers have no occasion for early folds, plenty of herbage have they on the pastures, many of them have mown a fair second crop of grass for hay.

THE ROYAL COMMISSION ON AGRICULTURE.--The second meeting of this body took place on Tuesday last at 23, Great George Street, Westminster, Mr. Shaw Lefevre, M.P., presiding. The other Commissioners present were Viscount Cobham, Sir Nigel Kingscote, Mr. R. Giffen, Mr. Everett, M.P., Captain Owen Thomas, Mr. Lambert, M.P., Mr. W. Long, M.P., Mr. J. Gilmour, Mr. C. Whitehead, Mr. C. N. Dalton, and W. C. Little, with the Secretary (Mr. H. Lyon), and the Assistant Secretaries (Mr. C. Crawford and Mr. F. Freeman Thomas). Five Assistant Commissioners were chosen to travel, four of them in England, one in Scotland, and gather information for the central body.

REMARKS.

- REMARKS.

 10th.—Nearly cloudless morning, overcast at times in afternoon, and fine evening.

 11th.—Dull early, and generally overcast till 1.30 P.M.; bright afternoon and evening.

 12th.—Clear and fresh, with warm sunshine.

 13th.—Sunny, but rather hazy.

 14th.—Almost cloudless early and in afternoon, but a good deal of cloud in morning.

 15th.—Warm, with brilliant sunshine almost throughout.

 16th.—Bright early, overcast after 9 A.M.; spots of rain in afternoon; wet evening and night.

A fine week with much sunshine, and rain on only one day. Temperature above the average.-G. J. SYMONS.

To many of the younger generation the meeting of the veterans, so pleasantly recorded in the pages of the Journal three weeks ago (page 236), must have been highly interesting, and if a young man's record of a young man's work may be allowed to follow the sketch of the veteran's longer experience I should like to give it. I felt tempted to ask at first for a special gathering of younger men round the council fire to whom to address my story, but after all it may be gratifying to the old chiefs of the gardening tribe to hear of those of the younger generation growing up around them who are animated by the same ideals, and endowed with the same sterling qualities. The time will come when the old workers must lay aside the spade and the pen, and it can hardly be other than gratifying to them to think that when that time comes their teaching will live on, and be developed to the common good as others have been before them.

High cultivation has but a vague meaning to many minds. Mention of it is usually received in a tolerative spirit as a something which, although devoid of practical shape, still merits respect as an admirable abstract principle. It is not looked upon as actually implying the production of good crops of fruit on trees which formerly yielded bad ones, or heavy crops of vegetables where the land originally gave light and unsatisfactory returns. But it is my present purpose to show that it has a tangible force and value, and that far from being an abstract theory it is a principle pregnant with practical results. It has been my good fortune to enter many well managed gardens this season, and the latest affords a splendid instance of what high culture can do. It is a Sussex garden, entered through handsome lodge gates about two miles past Crawley on the main Brighton road. The proprietor, Philip Saillard, Esq., is a wealthy merchant, who has made himself the owner of a vast estate, and has devoted time, money, and intelligence to improving it. The gardens are admirably laid out, the houses handsome and substantial, exhibiting excellence of material, workmanship, and design. Indeed, the whole place is such as the proprietor may well look upon with pride and satisfaction.

I turn now to the gardener's part, and so get at last to my story. The fruit at Buchan Hill, for that is the name of Mr. Saillard's splendid place, is a great object lesson to those who are unable to form any definite conception of the meaning of the term "high culture." The large, walled-in kitchen garden contains a collection of trees, which for skilful management, healthy condition, and productiveness, are not to be excelled in any garden which I have yet seen, and are equalled by very few. They are a remarkable example of the results which follow an intelligent prosecution of a few leading principles. As models of pruning and training, of health and cleanliness, and of fruitfulness, they are equally striking, and in whatever aspect they are considered they constitute an eloquent testimony to the advantages of culture.

The gardener, a young man named Martin, went to the place as foreman, and took full charge between four and five years ago. In that time outside witnesses, well capable of judging, tell me that he has effected an extraordinary transformation. For my own part I can only speak of the present, not of the past. Peaches and Nectarines on a wall facing due east are now in magnificent order, whatever they may have been a few years ago. They are huge trees splendidly trained, with healthy, well-developed, clean foliage, and

have carried good crops of fruit. Walburton Admirable, Royal George, Noblesse, and Dymond are four of the leading sorts. The trees were lifted last year, and are now well furnished with bearing wood. Lifting is the young gardener's prescription for barrenness. He practises it with all kinds. The labour must be great, but the results are unmistakeable.

A long stretch of cordons on the same wall as the Peaches have been recently planted. The quality of the material, as well as the nearness to Cheal's, suggests their birthplace. The espaliers, which run nearly all round the garden, are in first-rate order. They are well established trees, and have filled their allotted space. Enormous quantities of fruit are yielded by them. There is grand fruit of the two stewers, Uvedale's St. Germains and Catillac. Capiaumont is heavily laden, in fact the tree is brown with fruit, and almost the same might be said of Brown Beurré and Easter Beurré, while Beurré Sterckmans, Beurré Diel, Beurré Superfin, Pitmaston Duchess, and Beurré Hardy are bearing exceptional crops. So heavy is the burden of fruit that it is natural to express a doubt if the trees are not overcropped. But the growth, it is observed, is of the right sort, and by no means points to a debilitated condition. The secret is in the condition of the roots and the soil. Lifting and re-lifting, with the concomitant shortening of coarse "prongs," has resulted in the production of a network of feeding fibres, and the medium in which they ramify has been consistently enriched.

Even more noteworthy than the espaliers and wall trees are the pyramids. It would be difficult to produce a more perfectly healthy and fruitful type. Though termed pyramids, they are not so formal as the average tree of that class, and might almost be described as intermediate between the pure pyramid and the open bush favoured by many cultivators. The course of training pursued has evidently been conducted with a view to securing neatness and shapeliness without excessive formality. The bushes are open through the thin disposal of the main branches, which are 15 to 18 inches apart, and they bear magnificent fruit, which is of great size, and as smooth and clean as indoor Nectarines. The moderate extension that is permitted affords a natural outlet for the inherent energies of the trees, and their open character favours complete solidification and maturation. Root management is again advanced as one of the great factors in successful management. "Use the knife less and the spade more" is this young gardener's creed. Numbers of trees which never bore a good crop, the roots being in an unsatisfactory state, the soil exhausted, and the branches in a tangled mass, crossing and re-crossing each other, so that, as my companion put it, "you couldn't see half through them," are now bearing splendid crops. You can see all the way through them now, and a fine display of fruit is included in the survey.

This affords one side of the practical aspect which I have claimed for the term "high cultivation." In this garden, where the trees once gave but a poor return, they now yi ld produce that would shine prominently at any exhibition. I might pass for a moment from the type to a variety. Some of the finest pyramids are Pitmaston Duchess, and with these notes I hand the Editor two Pears from one of the trees. One is a large, clean, shapely example, weighing It was not selected, as there were many larger, but taken off at random. The other is a wrinkled, distorted, worthless fruit weighing 5 ozs. Four years ago the latter represented the crop, for the trees bore no other, now there is only one here and there, an ugly duckling amongst a full crop of large, handsome specimens, such as might have come off one of Mr. Thomas's famous Sittingbourne trees. The ugly ducklings would be laughed out of the market, the normal fruits would probably bring half a crown a dozen. There have been no mysterious processes brought to bear on the trees. They are the same specimens, and occupy the same places as when they were worthless; cultivation alone has brought about the change. They have been thinned, judiciously trained, rootpruned, and liberally fed, nothing more. The plain truth is that practical work and common sense have transformed them from cumberers of the ground and robbers of the soil into valuable and fruitful occupants of the garden.

There is a fruit arch at Buchan Hill about which a few words ought to be said. It is 17 feet high, 15 feet wide, and upwards of 300 feet long. The well known arch at the Lowfield nursery is a babe beside this giant. It is planted with cordons on both sides, and must present a magnificent sight when the trees are in full blossom. It is not less remarkable now, for many of the trees have met in the centre of the arch overhead, and are a rope—I had almost said a rainbow-of fruit. The trees on one side were lifted last year, and next season probably the other side will be similarly treated. Amongst the Pears Nouveau Poiteau, Marie Louise, Duchesse d'Angoulême, Pitmaston Duchess, Brockworth Park, Doyenné Boussoch, Beurré Diel, Beurré Hardy, Souvenir du Congrès, and Louise Bonne of Jersey are doing well; amongst the Plums Green Gage, Magnum Bonum, Peach, Jefferson, Diamond, and Victoria; amongst the Apples Alexander, Blenheim Orange, Lady Henniker, Cellini, Lord Suffield, King of the Pippins, Cox's Orange Pippin, Worcester Pearmain, Peasgood's Nonesuch, Loddington, and Lord Derby.

This wonderful arch has been established ten years, and it is a revelation to see what magnificent results are yielded by the cordon system when the trees have scope for free main extension, are well fed, and have their roots kept in good order. Every fruit grower in the kingdom would delight in seeing it, and indeed the whole garden. The kitchen garden is full of splendid pyramids, and the walls are packed on both sides with fruitful trees. All over the place, amongst the vegetable quarters, the fruit trees, and in the plant houses, the rule is heavy cropping and perfect cleanliness. The soil is systematically stored with nutriment, weeds are kept down and insects prevented, and the result is such full crops of splendid produce as are rarely seen. I am told that Mr. Martin is a tremendous worker, in the garden early and late. My own eyes have told me that he is a fine cultivator. This young practitioner is a credit to his craft, and one whom time will distinguish, unless I am much mistaken, as one of the leading gardeners of his time. His future, at all events, lies in his own hands. His work is a worthy tribute from one of the younger generation to the sound teaching of the old, and a proof that some at least of the rising school are prompted by high principles and energetic perseverance. —W. P. W.

HARDY FLOWER NOTES.

Though days grow short and cool, and falling leaves from trees and hedgerows bespeak the coming of the wintry days, when the wind shall whistle eerily through the leafless boughs, and the flowers which bedeck the garden be few and far between, as yet there is no want of brightness. The Sunflowers still glow; the stately Gladiolus still uprears its beautiful spike among the border flowers; the Pyrethrum has endeavoured, though faintly, to assume the beauty its flowers display in June; the Michaelmas Daisies have been most beautiful, with that soft beauty which renders these flowers so much in harmony with the sadder skies of these autumn days; some of the Campanulas still display on border or in the rock garden their spikes or sheets of cup or bell-like form; the autumn-flowe-ing Chrysanthemums, which here are treated practically as hardy herbaceous plants, adorn the borders with their brilliant blooms of various sizes; late-flowering Poppies, such as the charming scarlet and black Papaver umbrosum, are bright and attractive still, and many others lend gaiety to the garden.

The Meadow Saffrons have well nigh passed away, leaving joyful memories of the cups of the single or the ribbon-like petals of the double forms. No prettier flower of its kind exists than the double white variety of C. autumnale. Scarce it still is, but is worthy of a place in the garden of the choicest of hardy flowers. Their rivals, too, in the affection of the lover of bulbous plants—the Crocuses—have come or are coming rapidly into flower. They are doubly welcome prophets, so to speak, as they are of the spring when the Crocus is fully aglow with beauty, and in themselves choice as little gems which sparkle in the fainter sunlight of cloudier autumn. No one can see a clump of C. speciosus expanded in the sun with its blue-purple flowers so deeply feathered

without feeling delighted at the sight. Very fine, too, has been a clump of C. pulchellus which has come to me from the Bithynian Olympus. When they bloomed before it was on Asiatic soil, and now in this mild corner of Scotland they are blooming again, and one would hope may do so many years. Variable are these collected bulbs, some flowers being darker in colour inside, some with sharper petals, and others with deeper coloured feathering; but all are beautiful with their exquisite tint of blue, and when open showing the white anthers, which are a distinct feature of this Crocus, so worthy of the specific term "pulchellus"—beautiful. A charming companion to this native of the neighbourhood of the Bosphorus and the adjoining countries is the white C. hadriaticus, in flower here at the same time. This beautiful little Crocus from the Ionian Islands and Albania is quite hardy here, and its little white flowers are most delightful either when open, displaying its lemon-coloured anthers and scarlet stigmas, or when closed in in cone-like form. Other Crocuses are also in flower, but must be referred to again.

Very attractive for a long period, either on the rockeries or forming part of rockwork edgings to other borders, has been Linaria anticaria, a little alpine Toadflax which I have had in my garden for a number of years. Unfortunately, like many other Linarias, it cannot be said to be perfectly hardy, although for some years, when I first grew it, it survived our winters. Further experience leads me to the conclusion that it is not to be depended upon; but it seeds so freely here, and sows itself so readily, that my first sowing years ago has given me a constant stock of plants. One of the charms of this little Toadflax is its variable character We do not admire inconstancy in people, but what is a failing in them becomes with some flowers an additional attraction, and this Linaria, like the allied Snapdragon, varies much in colour. The plant forms a neat tuft of grey foliage, with little spikes of flowers well raised above the plant. These are very beautiful, varying much in colour and in shade, some having a white ground with a yellow lip, and spurs faintly lined with grey, and others of various shades of cream and of purple. L. anticaria is more easily retained in my garden than L. alpina, which I have had much greater difficulty in establishing.

One of the prettiest in its way of the dwarf Campanulas still

one of the prettiest in its way of the dwarf Campanulas still in flower has been C. soldanellæflora fl.-pl., an attractive little flower, now I understand ranked among the forms of C. rotundifolia. The flowers are blue and semi-double, the latter feature not being apparent unless on rockwork above the level of the eye or until the pendant flower is lifted to examine the interior of the bell. This pretty Bellflower should grow to about 1 foot in height; but as I prefer to keep it dwarf it is grown in a sunny position in very dry soil, where it does not grow more than 9 inches in height. Seed of C. soldanellæflora may be obtained, but only a proportion can be depended upon to come true, some seedlings showing flowers almost identical with those of C. rotundifolia, and others

having a number of narrow petals loose to the base.

A valuable plant all through the summer has been Polygonum sphærestachyum, the Round-spiked Knotweed, which has been much admired by all visitors to my garden who can appreciate hardy flowers (alas! that such a saving clause is necessary), with its spikes of blood-red flowers on stems growing here to about 18 inches in height. The spikes are about 1½ inch in length, and the brilliance of the flowers renders this perhaps the most attractive of the dwarf Knotweeds. It is growing in my garden in a low spot at the base of a rockery in free peaty soil, and having, what is necessary for this plant, a copious supply of water. Without this it suffers much; its allied species P. affine or brunonis being less particular in this respect, although the best plants I have ever seen had a plentiful supply. P. sphærostachyum is a native of the Himalayas, and although I have previously called attention to it this further note is hardly uncalled for, as so pleasing a plant cannot fail to give satisfaction to the grower. It is quite hardy in this neighbourhood.

Although I have not flowered it, nor have I even a plant at present, I may be pardoned for speaking briefly of a flower which on its introduction we heard a great deal of, but regarding which there is now an almost ominous silence in horticultural literature. This is Ostrowskia magnifica, introduced from Central Asia in 1887, and named in honour of Ostrowski, the Russian botanist. Those who have not seen an engraving of this plant will find one in the Journal of Horticulture, vol. xvii., 1888, p 53. There were great expectations regarding this Bellwort, but very few have been successful in its cultivation, and it is as much in the hope of receiving as of giving information that this note is penned. I have made several inquiries of hardy plant growers who have had this plant, and nearly all have, like the writer, lost their plants through causes variously reported as "severe winters," "slugs," or more frequently what may be called "sheer inanition," or "a premature and unwelcome death." A valuable horticultural work gives

instructions that the Ostrowskia requires the same cultivation as the tall perennial Campanulas. Would that this would suffice. My own experience is brief but typical. I had a plant which survived two winters in a border of good soil which would grow any other hardy Campanula quite well. The first summer it made a growth of about 9 inches, the second spring it grew about 4 inches and dwindled away. Those who are experimenting or hoping to experiment with O. magnifica would do well to be careful to protect the plant in early spring. Like many other Central Asian plants it makes growth early, and its fleshy structure seems to be easily injured by the severe frosts we often experience. I am aware that this plant has been flowered in England, but what we would like to know is, under what conditions? and was it treated as a hardy plant?

The hope which is said to spring "eternal in the human breast" has induced me to hope for several years that Zauschneria californica would flower in my garden, and with a desire to give it every opportunity of displaying what beauties it may possess, I removed my plant to the warmest position I could command—the top of a rockery facing due south, and close to a stone wall which shielded it from the north winds. Here, with a favourable season, this Zauschneria has deigned to yield a few open flowers; but as I write it is showing symptoms of retiring to its annual rest without opening many of the buds which have appeared. The few which have opened fail to exhibit the plant in its true character, and with great reluctance I have come to the conclusion that it must be discarded as unsuitable for our cool climate on the Solway. A similar tale of its behaviour has reached me from many growers, and if it has not been satisfactory in a year like this it is only occupying the ground, which would be better devoted to a more accommodating plant.

Possibly the same might almost be said of Plumbago Larpentæ, which I have had for several years, but which has only flowered this season. There is this very considerable difference, however, that P. Larpentæ has flowered very profusely, and that its deep blue flowers are particularly pleasing, and where it is grown here, on the top of a rockery, having a beautiful effect. I do not know that there is anything particularly required for its successful cultivation beyond a warm soil and situation. It is much admired, although its blooms are not of the same beautiful sky blue as the delightful greenhouse plant P. capensis, but are smaller and of a deep purple blue.—S. Arnott, Dumfries.

HABENARIA CARNEA.

THE exhibits of Habenaria militaris at the Drill Hall during the last year or two have drawn more prominent attention to this brilliant Orchid than it had previously received. Partly, perhaps, on that account, but largely owing to its intrinsic beauty, the new species carnea, placed before the Orchid Committee of the R.H.S. on the occasion of the great Show at the Agricultural Hall, received a considerable share of notice and criticism, which, on the whole, was of a favourable character, and a first-class certificate was subsequently awarded to it. In general character and expression the flower greatly resembles H. militaris, but it is larger and of a tender rose-tinted flesh or blush colour. Considerable interest attaches to this charming novelty, and the engraving (fig. 40) will therefore be welcomed. This Orchid was exhibited by Messrs. F. Sander & Co., St. Albans.

SPATHOGLOTTIS FORTUNEI.

SEVERAL pans of this terrestrial Orchid have been a noteworthy feature in the cool Orchid house at Kew for some time past. Though the individual flowers may not be so fine as in some of the other species, well flowered plants of S. Fortunei are very showy, and supply a welcome colour at a season when the Orchid houses are otherwise rather bare. S. Fortunei is a native of Hong Kong, where it was discovered by Fortune, who sent home pseudobulbs, which first flowered in this country in the gardens of the Royal Horticultural Society in 1845. The species is deciduous, and the flat, fleshy, underground pseudo-bulbs remain dormant for some months after the foliage has disappeared. During this period the plants require to be kept quite dry. S. Fortunei has a considerable resemblance to a Bletia (to which genus Spathoglottis is closely allied), and succeeds well under practically the

same conditions of culture. The narrowly lanceolate plicate leaves are pale green, and about a foot in length. The flowers are borne six to eight on a scape 12 to 18 inches high. They are about $1\frac{1}{2}$ inch across, of a fine clear yellow. The lip is threelobed, and the two side lobes, which curve inwards, are blotched with chocolate.—A. B.

AUTUMN TREATMENT OF DENDROBIUMS.

THE growths of many of these will now be completed or approaching completion, and every opportunity should be taken of exposing them to sun and air. Many of our Dendrobiums have for some time been standing out of doors in the full sun, but as the nights are getting colder they will be removed to the front stage of a vinery, where air is constantly admitted day and night. Here they will remain until they are wanted for flowering, as a long rest

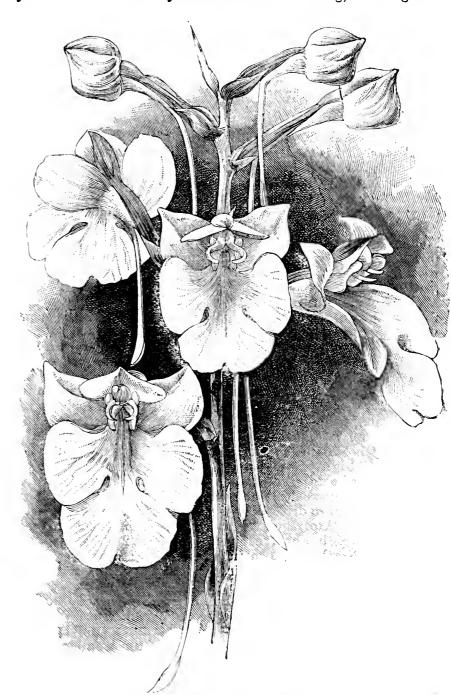

FIG. 40.—HABENARIA CARNEA.

in a cool dry atmosphere is the only means of getting a full complement of bloom in the spring.

There is a difference in the time taken by the various species to produce and mature their pseudo-bulbs. Some, like D. Dalhousianum, although started early in the season, will occasionally be still growing at the end of October or in November; others, such as D. thyrsiflorum, will often make two distinct sets of growths in a season, the time taken being usually about six weeks. D. Wardianum requires a long season of growth, and should be carefully watched and kept rather drier "at the roots and in the atmosphere" when nearing completion, as it is very apt to grow at the bottom before the new growths are matured, and may frequently be seen with young shoots 6 or 8 inches long in the middle of the winter. This is extremely weakening to the plants, and should be avoided in all cases where possible. D. Cambridgeanum and other autumn-blooming species should not be dried off too rapidly after flowering, but the water supply ought to be reduced gradually until the foliage withers and falls off, when it may be entirely withheld until the plants show signs of activity in the spring. D. formosum eburneum, and all spring-flowering Dendrobiums, must be

kept fully exposed to the sun, as it loses its power, a thorough hardening and ripening of the bulbs being most desirable.

A sharp look out must be kept for woodlice and small snails, which do much mischief at this season by eating out the flower buds of such plants as D. nobilis just as they are becoming visible at the nodes. A few pieces of Potato placed on the pots and examined every morning make good traps for the woodlice, while hand-picking by the aid of a light in the evening will be found the best remedy for the snails.—H. R. RICHARDS.

OUT OF TOWN.

Country people enjoy a visit to London during the season, and there is certainly plenty to see and hear in it, while Londoners enjoy a run in the country. My escape from the City was during the time of the great heat, and unfortunately there appeared to be more flies than breezes in the country. It was a sweltering run one evening from King's Cross to Peterborough. A carriage companion was going to the far north—Mr. Ross of the Scone Fruit Preserves. He had travelled from Perthshire to Kent the night before, and after noting that the crop of small fruit there would by no means equal the demands of the jam makers, he was rushing back to buy all he could, and thus literally steal a march on the southerners, whom he knew would have to go north for supplies. That is the way business is done in these days, and men have to be on the alert to make a living.

have to be on the alert to make a living.

The first stop was at Peterborough, convenient for a call on Mr. Harding of Orton Hall. A great change has taken place there since then in the death of the Dowager Marchioness of Huntly. The deceased lady was an ardent gardener and accomplished botanist. Not many persons had perhaps a better knowledge of British plants, and she was ever an assiduous collector of them. Her rockery afforded her much solace during a lingering illness, and gardening was one of the pleasures of her life. The Orton Wellingtonias with trees and Conifers are splendid. Mr. Harding's faith in the future of Thuia gigantea as a timber tree increases with experience. There are trees 60 to 70 feet high, and he with experience. expects they will grow as high again. Seedlings raised by him fifteen years ago are 30 feet high—beautiful specimens, and he does not know of any other Conifer, except perhaps the Larch, that would make equal progress. The timber of this Thuia is said to be of a very durable kind. Passing from the high to the low Mr. Harding was rejoicing over the New York Lettuce obtained from Messrs. Veitch & Sons, as affording the best of salads in the driest and hottest of summers. It seemed to partake of both the Cos and Cabbage type, and was as crisp and sweet as Lettuce could be. He says he does not know what he should have done without it, which is a good deal for a man like him to say, for it would take a good deal to drive him into either ecstacies or despair. He is a believer in Asparagus, too, as a paying crop, and of growing the plants in a single line on 2 feet wide ridges with 2 feet alleys between. The single lines have grown into broad ones; the ridges appear to be full of crowns, and judging by the growth of the plants in summer they may be expected to afford fine produce in spring. A profit of £50 an acre is Mr. Harding's estimate of first-class Asparagus culture, and he speaks from experience in growing, selling, and drawing the money—as good a test as could be desired. Fruit crops were abundant, but a crop of cones on Picea amabilis appeared to be as much valued as any other kind of fruit. Chaçun à son goût. I have no more to say about Orton, except to express appreciation of everything experienced there except the flies, and to state that Mr. Harding remains there as gardener to the Marquis of Huntly.

The next day the train took me northward, and not till passing Grantham, and swerving to the left, was a tinge of green to be seen in the pastures, but the freshness deepened as we sped along, and at Southwell all was verdant and refreshing. The entrance to the town is through an open park-like space, partly surrounded by lofty Elms, and beyond is the fine old Minster. It is a treey place is Southwell, and the land around is fertile. Just outside the town stands the pleasant home of Mr. Merryweather, and at a time when gardens were dried out in the south the nursery seemed as full of flowers as if drought was unknown. But we have only time for a glance, and have to see "Bramleys, and Roses" on our return from the Dukeries.

With his proverbial kindness Mr. Henry Machin, J.P., met us at ancient Worksop, and drove us to his charming home at Gateford Hill. A land of plenty it seemed, as the heavy crops of corn in the fields around swayed in the breeze, and the green crops were pleasant to see, thriving as they were, without a blank in the rows. Good land, good culture, cleanliness, and care were stamped on the face of the compact estate. One of the features to leave an impress on the visitor was the transformation of a drying ground,

on the stable side of the mansion, into a delightful rosery. A very

common sense arrangement it may be termed—a series of long beds about 4 feet wide, with glades of smooth lawn between them. All the blooms could be seen and reached, but the most charming effect was produced by the floriferous Polyantha Roses. Surely all the varieties must be there—not in isolated plants, but sheets or masses, the floriferous trusses rising from a bed of glossy green foliage, producing a delightful effect. That is the way to grow and show the Fairies, not dotting a plant here and there, to be "lost" among its larger congeners. Mr. Machin's exhibition Roses are grown under, so to say, field culture. He is a true Rose amateur—i.e., lover, for this is the English equivalent of the Latin amator, a lover. They are grown in a slice off a field, where they have plenty of air, and not in a garden confined. The young squire of Gateford has done very well as a beginner in showing, and will do better in the future. If he will take a hint from an older man, who commenced budding fifty years ago, he will give his plants liquid manure in the winter, and not be afraid to give it plentifully, and of twice or thrice the strength of a summer application. The best kind of all would be stable drainage, for soil of the texture displayed is seldom rich in potash; and at any rate more could not possibly do harm, and might be of marked benefit to the Roses. Let him try the experiment, and if it does not answer let him not treat his visitor so well if he should call again another year. He will risk incurring the penalty. After a walk through the enjoyable old world kitchen garden there is yet

nearly two hours to luncheon—just time for a drive to Hodsock suggests our friend, forthwith ordering another conveyance.

Hodsock Priory, the home of the Mellish family, is a familiar name to the readers of the Journal of Horticulture, as mentioned in connection with carefully compiled meteorological notes by Mr. J. Mallender, the gardener. The mansion is old, some parts of it very ancient, and the garden is in keeping with it, while Mr. Mallender is no novice, as he has been engaged at Hodsock for more than thirty years. Miss Mellish may be fairly described as a real garden lover, as indeed all the family are, and with her love for plants is combined knowledge. Garish show and formal effect are not sought for in this old-fashioned place. Plants are cherished for their individualities, and more pride would be taken in preserving some rarity and growing a plant needing special care, than in creating a sensation in colour with thousands of familiar bedding plants. Water plants, bog plants, hardy border plants, and old-fashioned Roses prevail at Hodsock; the border plants grouped in colours, such as white, pink, red, yellow, blue, and so on, according to Miss Jekyll's idea of arrangement, instead of the orthodox mixtures. The old time garden Roses are seen at every turn, but en masse in five or six V-shaped beds their points converging at the terrace platform. These beds are apparently about 50 yards long, and must afford cartloads of fragrant trusses. Then the lovely miniature or Polyantha Roses are cherished, and a round bed of them with a local novelty in the form of a hardy Pea covered with brick-red flowers, was much admired. The pleasant reception accorded by the family and Mr. Mallender was highly appreciated, but half an hour was all too short for inspecting the treasures of the garden at Hodsock.

After luncheon at Gateford and a quiet stroll among the Roses through the pleasure grounds our untiring host thought there was time for a drive to Clumber to see Mr. Slade, and have a look round the gardens in the cool of the evening, a happy thought well carried out, ending in all being satisfied with the visit. Clumber is a great place, and Mr. Slade is a "great" gardener, surely one of the greatest (if scaled) and his work is as good as he is weighty. Owing to the vicissitudes of life, to which high and low are exposed, Clumber was for years, so to say, deserted, and "Time's effacing fingers" left their mark behind. But an improving spirit is abroad now, and the present Duke and Duchess of Newcastle, whose goodness are on all tongues, evidently intend to make their splendid heritage worthy of its ancient fame. The garden structures are old, heavy, and out of date; but Mr. Slade, like a sensible man, makes the best of them, and does more than could be expected with them. His Pines, Peaches, and Grapes won honours where it is hard to win them—at Shrewsbury, and when this can be done under present conditions what may we expect after the restoration that will in due time be accomplished? first thought of the Duke appears to be the comfort of workers. A splendid new house has been built for Mr. Slade, one of the best gardeners' homes in the kingdom, and new bothies are in progress, which will combine every requisite for the comfort of the Fruits, plants, flowers, and vegetables are in great demand, and the supply is ample and meritorious.

The most commanding features of Clumber are the mansion, lake and pleasure grounds. The noble building overlooks an extensive terrace flower garden, the fountain in the centre having been cut from a block of marble weighing 50 tons. The lake of nearly 90 acres stretches away right and left till lost in the distance

beyond the trees. Beyond is forest scenery. On the mansion side of the lake are acres of lawn, stretching far away, studded with noble trees of various kinds, a few crowded, no doubt, but all cared for and everything in excellent keeping. Contiguous to the mansion is the new church, a splendid architectural ornament and beautiful within. A magnificent Turkey Oak affords an effective foil to the building, but is spoiling another tree, or this spoiling the Oak which would be a pity. When trees have been allowed to grow so long together so as to mar each other it is often difficult to know what to do for the best, but the Duke has a gardener whose experience and judgment will not lead astray in any matters connected with his charge. Clumber is a princely place, and Mr. Slade appears the right man for the position which he fills so well.

The shades of evening fall, and Mr. Machin drives us to the "Royal," at Worksop where we rest till the morrow, when we have to face the flies in Sherwood Forest en route from Welbeck to

Thoresby.—A CITY MAN.

WINTER-FLOWERING PLANTS.

THE time has now arrived when a general re-arrangement of the inmates of glass structures becomes necessary, so that those plants which have been refreshing themselves in the open air may again be placed under glass, where they will be safe from frost. In carrying out this work there is a general tendency to overcrowding, and a most unwise policy it is in the majority of instances, the exceptions being those plants which are only required to give cuttings in the spring, or others which are passing through a period of partial or total rest, and consequently make little or no top growth during the next few months. These may, for convenience sake, be placed closely together whenever a scarcity of room is experienced, but on no account should the plants intended for winter flowering be overcrowded, otherwise good results will not follow. Although with most of us there seems to be an inborn aversion to consigning plants to the rubbish heap, it is nevertheless sound policy to occasionally "weed" out with no unsparing hand weakly or unsightly plants in order to secure room for the full development of others, and thus prevent their drifting into the same unsatisfactory state. This practice may with advantage be carried out at the present time, so that the large numbers of plants intended for winter flowering which have during the summer months been grown in the open air or cold pits, may be arranged thinly in positions favourable to their well-being. True, it is not always possible to place each class of plants under the exact conditions which experience teaches us to be the best, but much may be done by giving the most important ones the best

Begonias.—Although these are not so much grown for winter flowering as formerly, several species and varieties are extremely useful for the purpose. Insignis, manicata, and nitida are three of the best that I am acquainted with. They are also very accommodating plants, and succeed well in old houses where many other plants cut but a sorry figure. Each of the trio produces flowers either pink or rose in colour, which are very useful in a cut state, and the two first-named make handsome decorative specimens for use in pots. Plants which have been growing during the summer in cold pits ought now to be removed to warmer quarters, where a night temperature of from 50° to 60° is maintained, under which conditions they will flower well during

the next three months.

Few plants are more useful than Bouvardias for supplying choice cut flowers especially adapted for arranging in sprays and buttonholes, provided they are well grown. Cold pits are excellent positions for them during the summer months, but they should receive daily syringings during bright weather to prevent attacks of red spider. After the plants have become established occasional applications of soot water and Clay's fertiliser are beneficial, promoting health, vigour, and cleanliness; indeed, if these matters are not attended to green fly, scale, and red spider will invariably establish themselves on the foliage. Should any of these insects be found upon the plants, the latter ought to be thoroughly syringed with a solution of Calvert's carbolic soap, mixed at the rate of 2 ozs. to a gallon of water. This I find is a safe and rate of 2 ozs. to a gallon of water. efficient insecticide. To flower Bouvardias well during the winter a light house or pit is necessary, and a night temperature of 55° to 60° should be maintained, with a rise of 5° during the day. If grown under cooler conditions a smaller number of flowers is produced. When much fire heat has to be employed to maintain those temperatures, special attention must be given to damping the floor in the house as well as to watering the plants, otherwise the insects above enumerated will give great trouble and severely check the formation of flower buds on the side shoots. If the top lights are left open a little way continually, except during very

severe frosts, the pipes kept slightly warm when the weather is not bright, liberal ventilation being given when it is, the plants will make

sturdy and floriferous growth.

The following varieties of Bouvardias give a good variation of colour, the majority of them being very free flowering:—Alfred Neuner, double white; Candidissima, white; Vreelandi, white; Elegans, scarlet; Etna, double red; Hogarth, scarlet; Maiden's Blush, rosy blush; Mrs. Robert Green, salmon pink; President Garfield, double pink; Purity, pure white; and Vulcan, scarlet. Humboldti corymbiflora, with its snow white and deliciously scented flowers, is always much sought after. It seems a pity it is not a continuous bloomer, like so many of the smaller flowered type. I find its flowering period seldom extends over a month or six weeks. This variety succeeds well if planted outdoors during the summer, provided it is given a warm sunny position and the plants are set far enough apart for the air to circulate freely between them. They ought to be potted early in September, and placed on the north side of a wall to establish themselves before being taken under glass. When in the latter position less heat and atmospheric moisture than the majority of Bouvardias require will suffice for Under such conditions the flowers produced the one specified. have much greater substance than when given the treatment recommended for other varieties.

Where flowers of Calla ethiopica are especially prized during November and December a number of plants should be kept in pots throughout the year. If these can be stood at the back of a north wall, away from overlanging trees, they continue to increase in strength throughout the summer months, and by the present time many of them will be showing flower spikes. I like to place these plants in their winter quarters by the end of the present month. Before arranging them in the houses the application of a rich top-dressing is of immense benefit to the plants. Loam and fresh horse droppings in equal parts with a 5-inch potful of Clay's fertiliser to a peck of the other ingredients is an excellent compost to use for the purpose. Light span-roofed or lean-to houses are the best for Callas, but not absolutely necessary, as I have frequently produced large numbers of flower spikes during the autumn months from plants in houses which were both lofty and heavy in build, but when grown under such conditions the plants always become more or less drawn, even when kept near the glass. The advantages of growing the earlier plants entirely in pots may be easily perceived, as much less artificial heat is required to bring the flowers out by a given date. Indeed good clumps which have been planted out are frequently weakened by applying strong fire heat to hasten the flower spikes as soon as they are seen. These which were planted in the open air and have not yet been lifted should be potted at once, and placed in Peach houses, vineries, or pits, till they can be removed to more favourable positions. These will supply bloom during the early spring. They are generally at their best about Easter.—LABOR OMNIA VINCIT.

PLAIN WORDS ON PRUNING FRUIT TREES.

(Concluded from page 271.)
WINTER PRUNING.

Apple Trees.—The operator should look over all his trees in the autumn immediately the leaves have fallen. If summer pruning has been properly attended to the winter work will be light; but many gardeners have not the time during the summer to attend to this matter, and consequently the pruning is left until the winter. This is not always advisable, inasmuch as the trees can be kept in better order by judicious summer pruning, and, moreover, made to produce better crops. In pruning a young tree the operator should consider the shape and form he wishes it to assume. Leading shoots for the formation of bush pyramids or espaliers should be well looked after. In pruning cut back to a bud that is on the outside of the shoot, which will help to keep the head open. Insert the knife directly opposite the bud, and then make a slanting cut upwards so as to come out a little over the bud. If the cut is made too low down the growth from the bud will be weak, and in some cases the shoot will get broken up by the wind. All dead branches and spurs should be cut away, as they give the trees an unsightly appearance. The heads of the trees must be kept open; cross branches should always be cut away, also any useless wood. The aim of the pruner should be to regulate the tree so as to give every leaf and bud sufficient room to develop; then if the roots have been properly attended to a good crop of fruit should be the result. If previous instructions have been carried out Apple trees will require but little attention besides shortening side shoots and to thinning the head to induce fruit spurs to form. As regards trees that have not attained their full size and the leading shoots have been left for extension, these should be shortened back to about 18 inches, pruning to an outer bud. This chiefly applies to bushes, which are the best for gardens. A standard tree after the head is formed will need little pruning besides the outling out of cross head is formed will need little pruning besides the cutting out of cross branches and not allowing the shoots to become crowded.

Pear Trees.—Pears on the bush system should be pruned similarly to the Apple, but trees that are growing against walls require different

treatment, so as to cover the allotted space. In pruning the young tree leave the branches about 12 inches asunder. The leader must be cut back to the proper distance, then three shoots will be required, one for leader and two for side branches. The latter will not require much shortening, as it is desirable to cover the wall as soon as possible. With some varieties it is possible to take two or more courses in one year. If a bud refuses to break, it is, in my opinion, a good plan to make an incision in the bark over the bud, which will check the flow of sap and

cause the bud to start into growth.

Peach Trees.—Assuming that a Peach tree has been properly attended to during the summer, and only sufficient wood laid in to replace that which has borne fruit, the latter should be cut away with a sharp knife close to the base of the young shoot which is destined to take its place for the next year's crop. Shorten the young shoot to where there is a wood bud. On some shoots it will be found that there is no wood bud except the terminal bud, in which case the shoot must be left at full length, as the fruit cannot come to perfection unless leaves are produced beyond it. To distinguish fruit buds from wood buds is a very simple matter. The former are full and plump, whereas the wood buds are thin To distinguish fruit buds from wood buds is a very simple and pointed, and are generally found between two fruit buds. When this is so the shoot can safely be cut back to the length required. Young gardeners and amateurs will avert much disappointment by carefully observing this one particular point.

Cherry and Plum Trees. These will not require much winter pruning beyond cutting away dead wood or thinning spurs, and in the case of full grown trees spurring back leading shoots not pruned during the summer. The Morello Cherry should be treated similarly to the Peach, cutting away all the old wood that has borne fruit to make room for the young shoots. Standards are better if left to themselves. Plums require but little winter pruning if properly attended to during the summer. Figs should be treated like the Peach, as they fruit on the new wood, which must not be shortened except to induce young shoots

for the coming year.

Bush Fruits.—Red and White Currants should be pruned hard back after the bush is formed, as the fruit buds form in clusters at the base of the young shoots. A young plant should be cut back to produce vigorous growth. Select four shoots to form the base of the bush, then at the next pruning cut them back, and from the young growths choose eight shoots, which will be found sufficient to form a bush. Keep the centre open. A good height will be from 4 to 5 feet. All shoots should be spurred in to the main stem. Black Currants require different treatment, as they fruit on the previous year's wood. A good practice is to cut out weakly shoots and encourage vigorous young growths, cutting away the old wood. Raspberries should be kept to four cancs in a clump; if more have been allowed to grow they should be cut away, and the remaining four shortened back to 4 or 5 feet.

Root-pruning.—All trees before they are planted should be examined, and all tap roots cut away with sharp knife. After these are removed cut away the bruised parts of the other roots to encourage the emission of fibrous roots. The greatest attention should be paid to this part of pruning. It is a good plan to train the roots to grow straight from the stem of the tree. All the roots that cross should be shortened. In young plants the roots should be shortened to about 18 inches from the stem. The root-pruning of old trees is rather a difficult operation, and should not be attempted by amateurs. In the case of an old tree that has never been pruned before, it is better to operate only on one side for the first year. Dig a trench not less than 3 feet wide and 2 feet deep, the distance from the stem and also the depth must be in proportion to the size of the tree. The trench being dug, examine the roots, and cut the ends off those which are bruised with a sharp knife. Thrust a spade beneath the ball of soil around the stem of the tree to sever any tap roots. The trench must then be filled in with fresh soil, and a good watering given. The following year the other side of the tree may be treated in a similar manner.—A WORKING GARDENER.

SOFT VERSUS HARD COLD WATER FOR PLANTS.

It would appear Mr. Dunn (page 271) has very little to advance in the shape of argument to further his ideas on this matter, or he would have published them, instead of indulging in a mere play upon words, and suggesting that my training and observation have been so limited as to render me incapable of realising what can be grown in large gardens. Such is Mr. Dunn's summing-up of myself. It seems he has already had sufficient of the real question, and would fain turn the matter into other channels. But that will not do. Your correspondent has on page 214, September 7th, described cold hard water as an "obnoxious drug," and little better than "slow poison" for plants. He suggests that I do not understand the meaning of the word "stubborn." He will find if he looks in his dictionary that it means "firm," the facts I adduced on page 239 are as firm this week as when they were recorded. Now, let him find, if he can, if pure hard cold water is by any authority described as an "obnoxious drug," and he may also, with advantage to himself, endeavour to trace the meaning of "poison." Both those epithets, as applied by him, are, in my view, grossly incorrect. He has committed himself to dicta, the truth of which he must prove before what he may say in other respects can have weight with intelligent readers.

His references to drained and undrained soil are beside the question, for plants fail in waterlogged soil whether the water is soft or hard, and there is more soft water than hard in quagmires. The relative values of warm and cold showers are not in question. He made a positive statement that hard cold water is an obnoxious drug poisonous to plants. He must either prove, withdraw, or modify that statement, or stand self-convicted on its inaccuracy. That is the point, and all arguments around it will be mere word spinning.

I have given instances of the water so unequivocally condemned by Mr. Dunn, proving of enormous value in the profitable cultivation of Grapes, Cucumbers, and plants. Hundreds of persons have seen the examples, and Mr. Dunn may see similar results in scores of establishments, where the best Covent Garden produce is grown. The question, I repeat, is not of one kind of water being better than another, but of hard cold water being "an obnoxious drug poisonous to plants." That is Mr. Dunn's astounding allegation. I have rebutted it with a narration of facts much too stubborn to be dissipated by any person who is so loose in his phraseology as Mr. Dunn has, to my mind, shown bimself to be.—J. B. R.

MUCH experience with "hard cold water" is my excuse for entering shortly in the discussion on the subject. If hard cold water were "slow poison" our prospects here for the future would be miserable indeed. During the whole of this year the rainfall has been so light that " soft water" has been quite out of the question for plants of any kind. So dry has been the weather that, instead of having all our tanks full of warmed water, they have been quite dry when pumping day came round, and by the time the water entered them plants of various kinds were quite ready to receive a supply. The only source of water here, irrespective of the small amount of rainfall, is one well dug in the chalk 250 feet deep. One would imagine the water drawn from such a depth is as cold as water can be in summer, and I think there is no doubt it is as hard as it is possible to obtain any. Within five minutes of the water being pumped from this well it has many times this summer been given to plants of various kinds, including Chrysanthemums and Calanthes. Grapes, Peaches, and Melons have also been refreshed with supplies of this hard cold water. He would be a bold person who would say any of these are being poisoned ever so slowly. While perhaps wishing that I could not only soften but warm this water before applying it to the roots and over the foliage, I find it is impossible to do either, so many are the calls upon our one well. We are thankful to take it as it comes, and will wait and see whether it proves to be "slow poison" or not. So far, I am bound to say, it appears to have had a distinctly nourishing effect.—E. MOLYNEUX, Swanmore, Hants.

EARLY PEARS.

In the Journal of Horticulture Dr. Jules Guyot has been recommended as a good Pear. I have fruited this variety as a cordon on a south wall for the past five or six years, and I do not think it is ever likely to be so valuable as Williams' Bon Chrêtien. It is, indeed, a prettier fruit, is sweet and good; but I have never had it so delicious as the old "Williams" when in perfection. Souvenir du Congrès has become very popular, no doubt on account of its large size combined with a prolific habit. Some wonderfully fine examples of this desirable Pear have been exhibited this year, and it is sure to be grown more largely than ever. My opinion is that a few cordon trees will yield a sufficient supply for most establishments. The old Beurré d'Amanlis is, I think, a more useful variety. Clapp's Favourite as a cordon has yielded some delicious early fruits of good size. It possesses the desirable property absent in most early Pears, of ripening a few at a time, so that from one tree a supply can be gathered to bridge over several weeks. It seems to make way very slowly, but is bound to become a standard garden fruit. I have a cordon tree of a Bergamot named Dr. Hogg. It is delicious, and follows Beurré d'Amanlis, ripening about the same time as Louise Bonne of Jersey. Another delicious autumn Pear of the same shape, but larger, is Fondante d'Automne. This, with mc, is later than Louise Bonne of Jersey.

I have planted several trees of Marie Louise, the most useful of early winter kinds. It is seldom we have too many tof this, as it ripens slowly and its season is easily extended by a little care in gathering and by keeping the later fruit cool. Moreover, no Pear sells better, as it holds a high character in the market. I have a young tree of Beurré Bachelier, a Pear which ripens earlier than the above, and is a most prolific variety. The flavour is, however, rather poor, and it is useful alone on account of its never failing to bear, and therefore of value in seasons when good Pears are scarce. Pitmaston Duchess produces enormous fruits, but it has the fault of the last-named without the redeeming quality of producing fruit freely. Where space is limited I should personally be inclined to leave it out. Hacon's Incomparable is

very good in some seasons, and bears freely every year.

The time will soon arrive when any new trees that may be wanted must be purchased. On this point I may be allowed to say that it is necessary to keep a supply of young fruitful trees. In some soils no doubt old Pear trees bear fruit with wonderful regularity; but in very many gardens the soil is so unsuitable that root-pruning and the best attention to the branches combined fail to produce trees worth the trouble they incur. I have some magnificent trees under my charge, but if I had not from time to time introduced young trees the Pear crop of 1893 in our case would have been a small one. With young vigorous trees, however, I shall have no difficulty in meeting current demands. I prefer maiden trees to those that are older. They can be purchased cheapiy, and the trees may be grown in any form it may be found necessary to train them. As a last word, let me advise intending planters to order trees at once, so that they can be planted before thewinter.—B.

THE LATE M. GUILLOT.

In common with thousands of Rose cultivators, I mourn the death of M. Guillot of Lyons. He has, as your correspondent, "D., Deal" (page 272), indicates, immortalised himself by his world-famous productions, such as La France, Catherine Mermet, and Ernest Metz, which have so many admirable attributes, such as those of form, of fragrance, and floriferousness, that they are not likely to be superseded or surpassed. He was unquestionably the greatest of modern French rosarians. As Mr. Wm. l'aul of Waltham has been for a long period the intimate friend of these, I venture to express the hope that he will, ere long, contribute to this *Journal* his personal reminiscences of M. Guillot. -David R. Williamson.

A LARGE MARECHAL NIEL ROSE.

In paying a recent visit to Knowsley Cottage, the residence of Thos. Pilkington, Esq., I found planted on the end and trained along a back wall of a vinery a fine Maréchal Niel Rose tree. The Rose under notice was planted some ten years ago, and is on its own roots. Twelve wires 9 inches asunder cover the back wall, and to each of these a shoot of the Rose has been trained, and the growths have reached a total length of $24\frac{1}{2}$ yards. The tree is in perfect condition as regards foliage, but canker has shown itself upon the older of the two stems from which the shoots are taken, the other being quite young and vigorous. A difficulty to its blooming freely was the free access of the roots into the Vine border. This has been overcome by a brick chamber built so as to confine the roots. After growth is completed the plants can now be given a period of rest. Good loam and liquid manure when in growth are what the plant feeds upon, and no mildew is to be seen. The shoots trained across the end of the house yield blooms a fortnight earlier than those on the back wall —R. P. R.

PEARS VERSUS PEACHES.

I FOR one cannot agree that "Pears are infinitely better and more profitable than Peaches" grown out of doors, because here I have abundant proof that the latter are more profitable than the former, given equal conditions as to site and culture. I am well aware that Peaches on open walls in several gardens are a failure, but why is it in many cases? Given a favourable locality I consider the Peach crop is the most certain of all hardy fruits when the trees are reasonably managed. I am ready to admit that in some districts where the situation is low there may be more difficulty in obtaining a full crop of fruit annually, but I am also well aware that in some of these gardens the trees are not managed in the proper way to secure the best results. When the soil is made rich enough by heavy manuring to grow full crops of vegetables over the roots of the trees, and when the foliage is permitted to be infested in the spring with black fly, to be followed with red spider in the summer, we may expect that outside Peach culture will be condemned. But is it fair?

Other mistakes besides those are continually being made, such as deferring the pruning of the trees until the spring, thus depriving them of a reasonable chance of maturing their wood. A lack of water at the roots is also another cause of failure with Peaches. Without sufficient moisture after the crop is gathered trees cannot prepare the fruit buds for the next year's crop of fruit. So long as such cultural points are neglected it matters little what locality Peach trees are found, the crop will be light, and the argument of "Pears being infinitely better" holds good. This, however, is not the right way to view the matter, and given equal conditions of situation I say that open air Peaches are by far the more remunerative crop.

I will cite an example on the remunerative side of the argument for the two sorts of fruit. A tree of Peach Grosse Mignonne, covering 30 feet of an 8 feet wall, this year ripened 300 good fruit early in the month of August. Every fruit could have been sold at the rate of 3s. per dozen, taking this as the minimum price. Growing against the same south wall are cordon Pear trees in really good condition. Fruit from the varieties Louise Bonne de Jersey and Duchesse d'Angoulême of the first quality would not fetch more than 2d. per lb. Now, who would say the same amount of wall space occupied with Pears would give the same return as the Peaches?

I do not stop at Peaches growing against south walls. I have this year gathered fruit of Late Admirable, weighed 10 ozs. each, from a tree facing east, and Royal George tree gave similar excellent fruit. Both these trees occupy a very much exposed site. Although these same trees seldom miss a crop of "blister," their healthy character otherwise seems to pull them through. We grow Peaches against west walls also, and with good results. Pears, I find, are much more difficult to sell than Peaches owing to the immense quantity that come from Jersey and France. When eighteen magnificent fruit of Williams' Bon Chrêtien can be bought in the market for 1s. 9d., what chance is there for English grown fruit? My experience is that fruiterers care but little for Pitmaston Duchess Pears when they can obtain fine fruit of Duchesse

d'Angoulême. So much as gardeners think of Jargonelle and Marie Louise Pears, there is a great difficulty to induce fruiterers to buy them. I am well aware that this has been an exceptional season for outside Peaches. We gathered our first fruit from an open wall June 24th, and have not been without Peaches since, and have still a few fruit. such sorts as Alexander to commence with, followed by Early Louise, Waterloo, Hale's Early, Bellegarde, Grosse Mignonne, Dymond, Royal George, Walburton Admirable, and Late Admirable, there need be no great difficulty in having an uninterrupted succession of fruit from the open walls. From the remarks of "C." (page 259), he would have us believe that when Peach trees are blistered during March and April it is useless to expect them to recover that year. This is not my experience, and I have to contend with east winds. If the trees are otherwise healthy "blister" should not prevent their perfecting a full crop of fruit.

As much as I like Pears it would never do to follow the suggestion of your correspondent and substitute Pears in all cases for Peaches. The great charm of a garden is the variety which it is made to produce, and this applies equally to hardy fruit. We must have proof positive that a fair trial has been given to the Peach trees before we dispense with them, especially when Pears will grow equally, or nearly as well, against other walls. Except in extreme cases I am hard to convince that Peaches are so difficult to cultivate on south walls. I know they have been condemned in many cases, but the judgment was misplaced. — E. MOLYNEUX, Swanmore Park, Hants.

SALWEY PEACHES RIPE IN SEPTEMBER.

WE are now (September 23rd) gathering large, ripe, and beautifully coloured fruits of the Salwey Peach from a tree on a south wall, the crops borne by three trees of that excellent late Peach Sea Eagle, occupying space on the same wall having been finished a fortnight ago. The supply, in the meantime, had been maintained by Lord Palmerston on a west wall, and Violette Hâtive on a wall having an east aspect. The trees of the last mentioned variety produced equally fine fruits as were gathered some weeks earlier from trees of the same kind growing

against a south wall.

It is certainly an advantage to growers who have to maintain a regular supply of ripe Peaches from as early as possible and as late into autumn as they can be obtained, to have trees of early and midsummer varieties on walls having respectively south, east and west aspects. By planting, say, two trees of Alexander, one on a south and the other on a west wall, Amsden and Hale's Early on a south wall, and another tree of the latter fine Peach on a west wall, a better succession of ripe Peaches is thereby secured than could otherwise be obtained. The succession to the supply yielded by trees of the above mentioned Peaches planted as indicated may be continued by such varieties as Dr. Hogg, Early Grosse Mignonne, Dymond, Royal George, Bellegarde, Violette Hâtive, Princess of Wales, Barrington, and Sea Eagle, planted all against south walls, or in the manner described above, a tree of Salwey being planted against a south wall to come in last, generally towards the middle or end of October. This is the first year in my experience for middle or end of October. This is the first year in me the fruit of the Salwey Peach to be ripe in September.

This being the time for transplanting home-grown trees and obtaining fresh ones the above remarks may prove as useful as they are opportune to intending planters generally, but more especially to amateurs, who may modify the plan recommended above to suit their own individual circumstances.—H. W. WARD.

LIVERPOOL NOTES.

THE AUTUMN SHOW.

As would be noticed by many of your readers from the advertisement in the Journal of Horticulture last week our autumn Show is to take place on Tuesday and Wednesday, November 7th and 8th, and not on the 15th and 16th, as previously arranged. According to the season this is a step in the right direction, for Chrysanthemums are rather early, and if bright frosty weather should come the former date will probably be more suitable for many good varieties. It has been a most trying summer, but there are certain to be some fine blooms. We are all looking forward to a wonderful display of fruit, which is of splendid quality in Lancashire, and the earlier date is without a doubt more suitable, for Pears and Apples are quite a fortnight or three weeks earlier than on former seasons. I may mention that liberal prizes are again offered,

SUCCESSFUL EUCHARIS CULTURE.

Owing to a breakdown of the heating apparatus in connection with the glass houses at Parkside, Huyton, the residence of J. A. Willox, Esq., M.P., the magnificent Eucharis in 12 and 16-inch pots were completely frozen through last winter and the foliage killed. To many persons the bulbs appeared useless, and, indeed, advice to that effect was freely given, but Mr. Wattie, the gardener, made an effort to save his plants. Some good loam (two parts) with the finer particles taken out, charcoal refuse, dried horse droppings passed through a sieve, and coarse silver sand were selected and mixed well together. Three or four hard bricks were heated and transferred to the centre of the compost. These heated bricks were used as a precaution against any danger from germs in the soil. Eight and 10-inch pots were scrubbed, drained, and half filled with the compost, on which some silver sand was placed, leaving all thus ready for the reception of the bulbs. The latter were not washed, nor does Mr. Wattie believe in washing with any solution unless the greatest care is exercised. The bulbs being dry the old soil was removed with a well worn hat brush, six being placed in an 8-inch and eight in a 10-inch pot. A little of the compost was then put in between the bulbs, and the pots stood on a boarded stage, the temperature of the house ranging from 65° to 70°, rising with sun heat. A watering was given at a temperature of 90°, and an occasional damping about the pots was all the moisture applied until growth had commenced, after which copious supplies were given. The freezing occurred at the end of February. Now the plants have massive leaves 6 and 7 inches across, pots full of thick white roots, and have produced an abundance of flowers during the past six weeks.

TOMATOES IN SHALLOW BOXES.

Is a deep soil necessary for the growth of the Tomato? was a question which occurred to me after leaving the Eucharis referred to above. In the early Peach house I noticed some grand well fruited plants, growing in ordinary cutting boxes 1½ and 2 inches deep and 18 inches long, placed on the narrow stage at the front of the house. The plants were trained to upright stakes, and there were two in each box. Good loam had been used in planting, with a top-dressing of horse manure given, and Sutton's A1, Hackwood Park, Carter's Traveller (a beautiful free setting, large and solid red fruits), and Golden Sunrise (the now well known yellow) were carrying heavy crops. They were some surplus plants which had been planted in the shallow boxes with the object of getting a few fruits from them. The lesson learnt is that good Tomatoes can be well grown in very little soil, provided the plants are properly watered.—R. P. R.

EVENTS OF THE WEEK.—But few events of horticultural interes will take place during the ensuing week. The special Show of fruit and vegetables which opened at the Gardening and Forestry Exhibition, Earl's Court, on Wednesday will remain open to-day (Thursday) and to-morrow. Several sales of garden produce, particulars of which have been advertised, will be held in the various auction rooms in the metropolis.

- THE WEATHER IN LONDON.—Since publishing our last issue the weather in the Metropolis has been of a variable character. Until Friday it was warm and summer-like, but on the day mentioned it became cold, as also was Saturday, when showers occurred. Sunday opened bright and comparatively warm, Monday proving colder, with occasional showers. Tuesday was mild, and early on Wednesday morning it rained heavily. At the time of going to press, however, it is fine. Slight frosts have occurred at night, but at the time of writing no damage has been done to tender plants.
- DEATH OF MRS, LATHAM.—We deeply regret to announce the death of Mrs. Latham of the Edgbaston Botanical Gardens, Birmingham, which took' place on the morning of the 24th inst. somewhat suddenly, 'after a' long and dangerous illness, from which it was hoped she was recovering. A very large circle of friends sincerely sympathize with Mr. Latham in his bereavement.
- TESTIMONIAL TO MR. THOMAS MANNING.—We have pleasure in announcing that the Committee of Gardeners formed for the purpose of offering to Mr. Manning some mark of respect on his retirement from active duty, have had gratifying support in the form of contributions towards carrying out the object in view. A large number of gardeners and others at once sent subscriptions, which are limited to 10s. 6d., to Mr. George Wythes, Syon House Gardens, Brentford, Treasurer of the Fund; or Mr. James Hudson, Gunnersbury House Gardens, Acton, London, W., Honorary Secretary. The subscription list closes on October 7th.
- GARDENING APPOINTMENTS. We learn that Mr. James Gibson, recently of The Oaks, Carshalton, a first-class vegetable grower and exhibitor, as well as an all-round horticulturist, is about to enter the service of A. H. Watts, Esq., Devonhurst, Chiswick, as head gardener, where it is hoped he may find ample scope for his abilities. Mr. A. Aitkins, for the past two years foreman under Mr. Lewin at Drumpellier, N.B., has been appointed gardener to Colonel King-Harman, Newcastle, Ballymahon, Ireland. Mr. W. Adams has been appointed head gardener to Mrs. Walker, Rydinghurst, Cranleigh, Surrey. Mr. G. Phillips, late gardener to W. Banon, Esq., Taplow House, Maidenhead, is appointed head gardener to the Rev. G. W. Corbit, Sundorne Castle, Shrewsbury.

- —— It is with unfeigned regret that we announce the death of MISS SARAH LLOYD, daughter of the late well-known florist, Mr. Lloyd of Sheet, near Petersfield. Mr. Lloyd's specialty was the Tulip, of which he possessed a very choice collection, and which his daughter has carefully tended since his death in December last. Miss Lloyd was also an ardent florist. She died, after a short illness, at her residence at Sheet on the evening of the 25th inst., deeply regretted.
- THE GRAPE CROP IN AMERICA.—Grapes in the Lake Erie region, according to an American exchange, are looking fine. From Dunkirk, in Chautauqua County, to Cleveland, Ohio, the crop has more than a usually promising appearance. The vineyardists of that section have long recognised the importance of exterminating weeds and of cultivating the Vines as carefully as other crops are cultivated. Some of their vineyards, containing from 25 to 50 acres, and laid out with extreme regularity, are indeed a beautiful sight.
- THE CURRANT CROP IN GREECE.—While most countries have suffered from poor crops this year, Greece has been exceptionally favoured. The Currant crop amounts to 160,000 tons, while last year it was only 112,000 tons. Again, the crop of Olives is reported to be three times as large as it was in 1892, and the Wheat crop is also said to be good. The agricultural population, therefore, of Greece, ought, one would think, to be prosperous. There is, of course a grievance, on account of the low price of Currants. The new crop is selling at 8s. a cwt. to London or Liverpool, which is a sad falling off from last year, when there were buyers on the same terms at 19s. a cwt.
- —— SINGLE CACTUS DAHLIAS.—Messrs. Dobbie & Co., Rothesay, N.B., send us blooms of a new type of single Cactus Dahlias that has been distributed by them this season. The flowers are of medium size, with reflexed florets of various colours. For decorative purposes these Dahlias are undoubtedly useful, but they will not find favour with everyone, no more than the single Chrysanthemums do. The flowers sent, however, are fresh, and among the named varieties Highland Mary, rich scarlet; Meg Merrilies, lemon yellow; Guy Mannering, blush; and Robert Burns, purplish magenta, are specially good. Blooms of some unnamed seedlings of merit are also noticeable in the same collection.
- —— Shrivelled Potatoes.—The case to which "Middledale" (page 266) refers of Potatoes being found in a flabby or soft condition is not at all novel. I have often met with tubers in a similar condition, and have always attributed it to scald from occasional very hot sunshine. It is usually found where the tubers are very thinly covered with soil, or has sometimes occurred where through some accident the plant stem has been injured, and soil partially removed from the tubers, thus exposing them to undue heat. Of course it is a case that seldom occurs, and for that reason it is of little importance. Still, whenever oddities in any garden product are found it is but natural that anyone should wish to know the why and the wherefore.—A. D.
- THE SIREX GIGAS.—I was surprised to read on page 279 that this beautiful insect "has been taken in England but very rarely." I have at odd times taken a few insects, and retained them as objects of interest, and now have some fine specimens. They do not appear rare in our neighbourhood near Bath. I take it that this insect has not an actual sting in the ordinary sense of the word. I have handled them when alive, but have never been stung; this, of course, does not go for much. The very wonderful tail that the female has, often more than half an inch long, is not a sting, though it is quite possible it might inflict injury on the skin; but its use is to pierce the wood in order to lay its eggs therein, and the Pine forests in some countries are often much injured by this gigantic sawfly. Wood calls this instrument a gimlet.—Y. B. A. Z.
- THE ROYAL GARDENERS' ORPHAN FUND.—We learn that a large committee of gardeners of Kingston, Surbiton, and district, including the leading members of the fraternity in that locality, with Mr. T. Cushon, Norbiton Hall Gardens, as Chairman, Mr. E. Bennett, Hampton Court, Vice-Chairman, Mr. W. Furze, Roselands, Teddington, and Mr. A. Dean, Kingston, Secretary, has been formed for the purpose of promoting a grand concert in aid of the above Fund, at the Surbiton Assembly Rooms, on the evening of October 25th. A strong effort is being made with considerable success to secure an influential list of patrons. The concert is being furnished by Mr. W. Furze, who is himself an excellent amateur vocalist, and who promises a first-class programme. The effort is a somewhat ambitious one, but it is hoped that with some active canvassers in the district tickets will be largely sold and a great success achieved.

- FROST IN SURREY.—A Godalming correspondent informs us that 5° of frost occurred last Saturday night in that district which destroyed all the Runner Beans, Vegetable Marrows, and plants of a similar nature.
- CASSIA CORYMBOSA.—Mr. H. R. Richards, Roche Court, Salisbury, writes:—This fine old plant has been flowering here continually since June, and seems likely to go on for another month at least. There are but few better plants for standing out of doors in vases, and a great point in its favour is the comparative immunity which it enjoys from insect pests.
- A SPARROW TRAP.—I want to make a fortune (vide page 265). Sparrows are easily tamed by feeding them regularly for a few days near the doorway of an outhouse, gradually introducing the food to the interior. The sparrows will soon enter freely and confidently. When many are inside close the door by drawing a string or other contrivance previously arranged. "Country Amateur" will then have them, and can send the fortune, care of the Editor, to—W. T. B.
- WAKEFIELD PAXTON SOCIETY.—There was a brilliant display of Tuberous Begonias at the rooms of this Society on the occasion of a recent meeting, when Mr. Vere, gardener to Mr. W. H. Stewart, J.P., of Milnthorpe House, read a practical paper upon their culture. In the paper he pointed out that under suitable conditions Begonias would prove formidable rivals to the Pelargoniums. It was, he said a novel and pleasing change, beautiful alike in foliage and flower, and produced a display with which no other class of plants could vie. Mr. J. G. Brown presided, and Mr. Thomas was Vice-Chairman. There was a good attendance.
- MICROBES ON ROOTS.—A correspondent sends us the following cutting:—"'Symbiosis' is a word used by scientists to describe the peculiar relations which have been found to exist between various microbes and the roots of plants to obtain necessary food. The Leguminosæ—such as Peas and Clover—are well known to be assisted very considerably by a microbe which forms tubercules on the roots, and multiplying exceedingly there little colonies of microbes 'manufacture' nitrogen in large quantities. The fungus or microbe feeds upon organic matter, but does not make it, whilst plants with green leaves make organic matter, but do not use it, so that both green-leaved plants and fungus work or 'manufacture' for each other, but not for themselves."
- This young Society means business, for it wound up its summer session by holding a largely attended and most enjoyable soirée at the Albany Hall, Kingston, on Wednesday evening last, and opens its autumn session on Tuesday evening next, October 3rd, in their new rooms in Eden Street, when Mr. Jas. Martin, the able foreman to Messrs. Sutton and Sons, Reading, will have an "Evening with the Begonia," a theme upon which he is specially entitled to speak. J. P. Trew, Esq., the President, will take the chair on that occasion. The session will close on December 12th with a "Chat about Chrysanthemums" by Mr. H. J. Jones of Lewisham, when it is hoped that the President of the Chrysanthemum Society, Mr. Alderman Sherrard, will preside.
- SUNDERLAND GARDENERS' IMPROVEMENT SOCIETY. On Wednesday, September 20th, the members of this society (upwards of forty) held their excursion to Hutton Hall Gardens, the seat of Sir J. W. Pease, M.P. They were kindly met at the station by Mr. McIndoe, head gardener, and Mr. Funnel, estate agent. Mr. McIndoe conducted the party, and explained the various fruits, including the cultivation of Vines, Figs, Tomatoes, and Citrons, the houses of which extend nearly three miles (?) The pleasure grounds were next visited, and the Coniferæ were much admired, the marked difference in the atmosphere between Sunderland and that district being clearly apparent. The company then adjourned to the boathouse (a remarkable structure of rusticity), situated at the end of the lake, and on the invitation of Mr. McIndoe partook of a substantial luncheon. Mr. Funnel then conducted the party over the hills and estate, including the stables. The party next proceeded to Guisborough and viewed the priory, abbey, and gardens, then dined at the Buck Hotel, Mr. Bolam, F.R.H.S., the Chairman of the Society, presiding. Mr. McIndoe proposed, "Success to the Sunderland Gardeners' Society," and regretted that distance prevented him becoming a member, but he promised to read a paper on fruit growing. The health of Sir J. W. Pease, Mr. McIndoe, and Mr. Funnel were enthusiastically drunk, and also the host and hostess. The party arrived home at 9.30 P.M., after enjoying a pleasant and harmonious day.-JAMES WATSON, Hon. Sec.

- A NEW HYBRID CLEMATIS.—Monsieur André describes in a recent issue of the "Revue Horticole" a new hybrid Clematis, produced by a French horticulturist at Lyons by fertilizing Clematis Pitcheri with the pollen of C. coccinea. This new Clematis is said to have preserved the vigour and the numerous stems of the strong-growing C. Pitcheri, and the brilliant colour of the flowers of C. coccinea.
- Destroying Weeds.—On page 265 "W. R. Raillem" contributes an interesting note on eradicating fleshy rooted weeds. Like him I have been very successful in destroying Bindweed, Tassilago, and other fleshy rooted kinds, and like his informant I had my information from a grand old gardener—viz., the *Journal of Horticulture*, which also exposed the folly of allowing weeds to seed before attempting to root them up.—N. B.
- GARDEN GUNS.—Mr. E. P. Timmins, Balsall Heath, Birmingham, claims by the invention of catapult guns to have overcome the difficulty of clearing cats, rabbits, and similar destructive animals from gardens. These guns are made in various sizes, are perfectly silent, and no licence is required to use them. Mr. Timmins has also produced a useful contrivance called the "Beak-weeder," by which Plantains and other weeds can be easily removed from lawns and walks.
- DISTRIBUTION OF SURPLUS PLANTS AT THE LONDON PARKS.—As winter is approaching it is announced that the surplus bedding plants will be distributed to the public on application to the superintendent at the various parks on the undermentioned dates:—Battersea Park, 24th October; Myatt's Fields, 21st October; Ravenscourt Park, 21st October; Royal Victoria Gardens, North Woolwich, 14th October; Southwark Park, 27th October; Victoria Embankment Gardens, 13th October; Waterlow Park, 18th October. Many amateurs in and around the metropolis will doubtless avail themselves of these opportunities to obtain plants.
- FORMOSAN CAMPHOR.—One of the chief staples of Formosa is camphor, but the industry is carried on under somewhat unusual conditions. Mr. Hosie in his late report on Formosa says that the Camphor Laurel grows in the savage territory only, and the hillmen or Hakkas, who border on that territory, have to make arrangements with the savage chiefs to protect or refrain from destroying the stoves or stills which the former set up in their country. As soon as the hillmen have settled all preliminaries with the savage chiefs and a suitable spot has been fixed among the Camphor trees for the erection of a still, the former proceed to run up a shed or rough building, the size of which depends on the number of stoves it is intended to contain. If ten are to be erected the building would be about 20 feet long by 12 feet or 13 feet broad. In the centre of the floor an oblong structure, some 4 feet high, 10 feet long, and 6 feet broad is built of sun-dried mud bricks, having five fireplaces or holes at each side raised a foot or so above the floor of the room. The two ends of the structure are solid and without fireplaces. The latter are so built that an earthenware pot can easily be inserted above the fire in each hole. An earthenware cylinder connects the mouth of each pot with the surface of the structure or still; between the pot and the lower end of the cylinder there is a round thin piece of wood fitting both the mouth of the pot and the lower end of the cylinder, and perforated so as to allow the steam from the water in the pot to pass into the cylinder during distillation. The top of each cylinder is usually about a foot in diameter and is level with the surface of the still. Such a still would present to the eye a mud structure, with ten round holes on the top and five fireplaces at each of the two longest ends. To complete it, however, ten large earthenware jars are required. These during the process of distillation are placed inverted on the top of the still immediately over the upper ends of the cylinders so as to form condensers. To prevent the escape of steam from the condensers bands of jute are fitted firmly between their mouths and the top of the still. The pots are filled with water and the cylinders with camphor wood chips; the jars are in position on the top of the still, and the firewood is lighted under the pots. When the water boils the steam passes up through the perforated wood into the cylinders, heats and moistens the chips, and ascends to the condensers, carrying with it the camphor fumes which the chips have given forth. The steam then condenses on the inside of the jars, and when the latter are removed a layer of white camphor crystals is found adhering to them. This is brushed off by hand and placed in baskets. The chips are then withdrawn from the cylinders, fresh chips take their place, water is added to the pots, the condensers are again placed in position, additional firewood is thrown into the fireplaces, and the work of distillation recommences.

— SUGAR CANE DISEASE IN BARBADOES. — The steamship "Atrato," which arrived at Plymouth a few days ago, brings information of a destructive cane disease that has developed itself at Barbadoes during this season, and is causing considerable alarm among the sugar planters. Nearly every estate in the island is losing its sugar crop. The plants are attacked at their roots, which rot and the plants perish.

COPPERAS IN PLANT MANURES.—"Suburban" sends us the following extract for publication. "Since the successful application of copperas or ferrous sulphate in the treatment of plant disease has become known, manure manufacturers have been in the habit of mixing this salt with the other ingredients of a manure, more especially in the case of phosphates. The advisability of this practice has recently been investigated by authorities. From a number of experiments they have drawn the conclusion that the addition of copperas has a deleterious effect upon superphosphates, that is to say, on mono-calcium and bi-calcium phosphates; but when tri-calcium phosphate is treated with copperas, a considerable portion of the phosphoric acid is rendered soluble in ammonium citrate, hence the action is beneficial."

— Bedding Begonias were at Yeovil, where Mr. B. R. Davis has collected a remarkably beautiful selection of plants, doubles chiefly, for the doubles seem in respect of massing effects to be productive of more pleasing effects than do the large-flowered singles. The plants put out in large numbers range from 7 inches to 13 inches in height, the tallest, Clemence Demeart, of a deep rose colour, giving a most charming effect, and the dwarfest, Dandy, a rich deep red, about 7 inches. Cactus is a beautiful reddish cerise, 8 inches high; Postboy, salmon carmine, 10 inches, are but a few of many that constitute a splendid strain. Whilst some are of continental origin, not a few are of Mr. Davis's own raising, the general collection of double and single large-flowered varieties is of the best grown, the new bedding forms may well rank as unique of their kind.—D.

Wonders of the Cotton Plant.—The Cotton plant, which has for so many centuries furnished a large part of the population of the globe with clothing, seems to be almost without limit in its usefulness. From the seed a valuable oil is expressed, while the husks form an article of food for cattle in the shape of cakes. From the lint which clings to the seed after it has passed through the "gin" felt is made, while the oil extracted from the seed is applied to quite a large number of purposes. But, according to the British Consul, Mr. Portal of Zanzibar, Cotton seed is also capable of yielding sugar. A process, 'Public Opinion" remarked recently, has been discovered for extracting sugar from Cotton seed meal, and though the details of this process have not been disclosed, it is said that the product obtained is of very superior grade, being fifteen times sweeter than cane sugar and twenty times more so than sugar made from Beet. This indicates that sweetness is not due to cane sugar, but to some chemical.

- SNOWSTORMS.—On Saturday morning a severe snowstorm was experienced over a great portion of the north of England. Snow fell so thickly that in a few minutes everything was covered to a depth of 3 or 4 inches. The weather in the district up to the present week had been unusually fine, but bitterly cold during the last day or two. The fall of snow lasted several hours. There has been a snowstorm in north Westmoreland, and the Pennine Hills are covered with snow. Snow fell in Annan early on Sunday morning. The flakes were unusually large, and the ground was covered with snow 1 inch deep. On Saturday soft snow fell heavily in Newcastle, and at night the weather was very cold. There has been no rain in the neighbourhood for many weeks, and the danger of a water famine has compelled the water company to cut off the supply to households for about fourteen hours a day, and pump water from the river for the use of manufactories. Dense hailstorms swept over parts of North Wales on Saturday, and the first snow of the season was to be seen on Snowdon. The districts of Hitchin, Luton, and St. Albans experienced a decided change in the weather on Saturday morning, when a strong north-easterly gale swept across the country. Several hailstorms prevailed at intervals, while between Hitchin and Luton there were occasional slight falls of snow.

VINE PROBLEMS.

OF the three questions propounded by "Experimentalist" on page 268 last week, No. 2 is the most interesting to me personally from having had considerable experience in raising Vines from seed, and I will, therefore, deal with it first and principally. It is, unfortunately,

not stated whether the seedling in question (taking it for granted the case is fact, and not merely theoretical) resembles in wood and foliage the male or female parent, as in the latter case I should be inclined to draw the conclusion that no actual cross had been made, and that the difference in fruit was merely the result of seminal variation. The crossing of Grapes is a delicate operation requiring very great care and a certain amount of manual dexterity, or the flower is self-fertilised before the foreign pollen is applied, and in the majority of cases which I have investigated where crosses were supposed to have been effected the rough and ready methods employed made it absolutely impossible to say whether any real cross-fertilisation had been accomplished or not.

Seedlings from self-fertilised flowers generally follow the parent pretty closely in habit, though the fruit may differ considerably in flavour and colour; but seedlings from a genuine cross will differ immensely, especially when the parents are not nearly related, in support of which it may be mentioned that a number of seedlings raised by my father from the American Strawberry Grape crossed with the Black Hamburgh had foliage varying from less than the size of one's hand to one which overlapped a sheet of the "Times."

I have at the present time an interesting study in heredity in the shape of seedlings from Gros Colman and Black Hamburgh crossed with the Strawberry Grape, the offspring in both cases resembling the male parent closely in foliage, peculiar perfume, intense flavour, and diminutive bunch and berry, the last two points of course rendering them commercially valueless. I ascribe the prepotency of the Strawberry Grape, even when used as a pollen parent, to the fact of its having been but recently reclaimed from the wild state, while our older Eastern varieties have been constitutionally weakened by long generations of cutting propagation.

Questions 1 and 3 are matters of history, and therefore better dealt with by older writers; but it seems probable that if an instance of a genuine sport could be produced it would be found to agree with the description in Question 1, just as in the case of plants grown for their flowers (notably Chrysanthemums); the sport, while differing widely from the parent in colour of bloom cannot be distinguished from it in habit and foliage.—Chas. E. Pearson, Chilwell Nurseries, Notts.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE next meeting of the General Committee will take place at Anderton's Hotel, Fleet Street, E.C., on Monday evening, October 9th, at seven o'clock. On the termination of the ordinary business of the Committee Mr. Charles E. Pearson, of the Chilwell Nurseries, Notts, will read a paper on "How to Improve our Chrysanthemum Shows," and discussion will be invited.

KINGSTON CHRYSANTHEMUM SOCIETY.

More than usual interest attaches to the annual Exhibition of this Society on November 7th, as there will be two champion vases competed for, the first being restricted to three previous winners only, the second one of course being open to all comers. Chrysanthemums seem to be grown in the locality more largely than ever, and in spite of the season they never looked better. A severe competition in all classes is expected.

BIG BLOOM CULTURE IN FRANCE.

THIS is a subject that seems to have agitated the minds of French growers not a little. While many appear to affect a sort of contempt for the method we adopt to secure exhibition blooms there are others who are undoubtedly desirous of giving it a practical test. Most of the pamphlets and articles published on Chrysanthemums in France have contained allusions to the big bloom method, and one or two cultivators like Mr. Phatzer and Mr. Calvat have successfully put it into practice. A Mr. Thibault of Nantes has, however, recently published a small treatise on the subject, borrowed principally from Mr. Edwin Molyneux's well-known book on "Chrysanthemums and their Culture," It is illustrated with several reproductions from Mr. Molyneux's excellent little volume, which appears to have formed the basis of more than one continental work on the popular autumn flower.

CHRYSANTHEMUM BUD MITE.

ALTHOUGH the Chrysanthemum sprays dispatched by your correspondent, "G. B. A.," from Scotland on September 8th did not reach me until the evening of the 11th, they were quite fresh, clean, and undamaged by the post office punches. This condition is absolutely

essential for a satisfactory examination of specimens. The three sprays were packed in damp clean moss in a stout cardboard box; growth sturdy, leaves deep green, glossy, thick, leathery, and without speck or blemish. The buds crowning the three sprays, one to each, appeared small (for the time of year), but normal, and had apparently nothing the matter with them. "These buds were taken early, and have remained in nearly the same state for about six weeks," stated "G. B. A.," also that they were taken from a plant of Wm. Holmes.

Denuding a spray of its leaves it had the appearance shown at A (fig. 41), natural size. The side buds (a) had been taken off six weeks ago, leaving the crown bud (b) only. This bud was slightly tinged at the apex (a) with brown. Removing the bud scales, the inner portion

to upset its equanimity. It will be noticed that there are no "buds" (or eggs, as they are sometimes called), nor were any discovered in the other parts of the dissected Chrysanthemum bud; in fact, gemmation had ceased, evidently some time ago, and only a few "bud" sacs were found. But in the older and unbrowsed erineum and suspended in it I found what I take to be the transformation stage of the four-legged (larva) mite into the six-legged. This is shown at G, and the empty case from which the six-legged mite emerges is represented at H. The six-legged mite itself was not found, but to assist others to recognise it it is shown at I. It is the female form—a most active and interesting creature.

The mite is not by any means uncommon, though hitherto unnamed

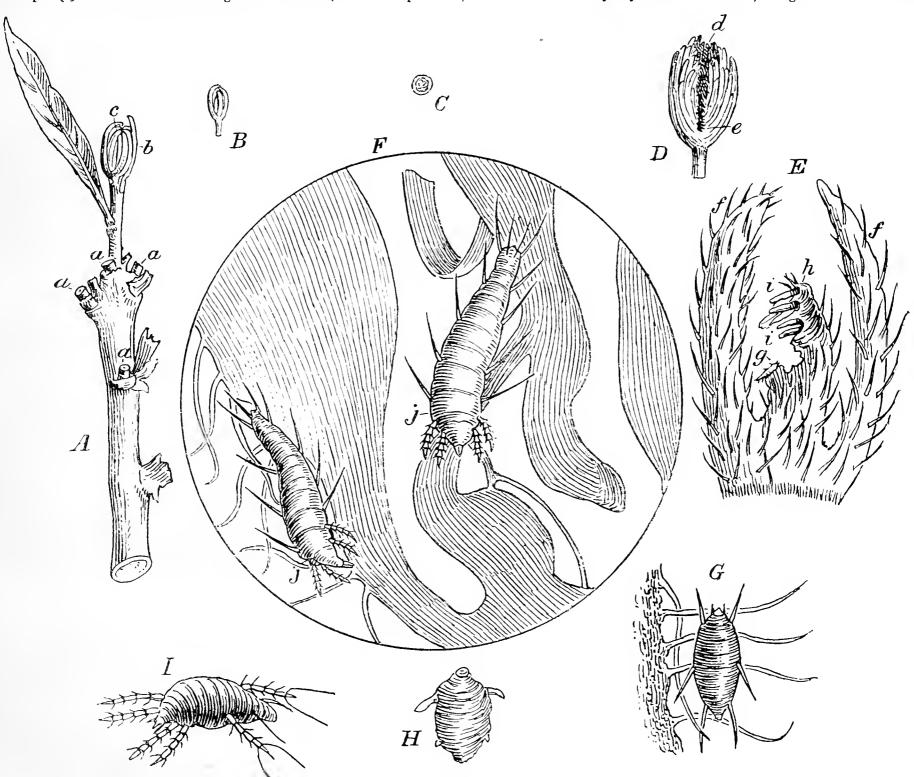

FIG. 41.—CHRYSANTHEMUM BUD MITE (PHYTOPTUS CHRYSANTHEM!—Abbey).

or embryonic flower was the size shown in vertical section at B, and in transverse section in C. Nothing was manifestly wrong with the bud as observable by the naked eye. Subjecting the section B to an ordinary pocket magnifier it had the appearance represented in D. Still no trace of any parasite was to be found, but the brownness at the apex pourtrayed in black (d) was seen to extend down the flower bud and to the base of the embryonic petals (e). Taking this portion only of the section and subjecting it to a lens of moderate magnifying power it appeared as shown in E; f, petals with hairs or erineum; g, mite; h, "bud eye;" i, cases from which the parthenogenetic mites emerge. Cutting a microscopic section—that is, a thin slice with the aid of a lens, and placing it on a glass slide and examining it with a powerful lens, two mites were seen as shown in F at j. They are full grown—the last of the parthenogenetic series, nearly 1-200th of an inch in length and about 1-900th of an inch in breadth at the widest part. The full scope of the microscope on the section is given to show that there is no erineum on the right hand side, where the mite is full fed, torpid, and beginning to thicken, but that on the left hand side was active amongst the erineum, moving about as if nothing had occurred

and undescribed. I propose, therefore, to name it Phytoptus chrysanthemi, the Chrysanthemum bud mite. It is unquestionably a native species, found in the buds of Chrysanthemum Leucanthemum or Leucanthemum maximum, the whole of the flower buds of this plant often being what is termed "deaf." In some gardens the plants flower profusely, in others only few flowers are produced, though the plants are perfectly healthy and strong growing. Some of the flowers are deformed, perhaps the florets only develop on one side, because the mites destroy the buds.

It also proves disastrous sometimes to Centaurea montana buds, they also being occasionally flowerless; but it is chiefly confined to the Chrysanthemum family—in fact, it is doubtful if the species are identical. But there is no question about the Chrysanthemum mite of our gardens and fields attacking the buds of Chrysanthemums. It generally fastens on the crown buds, the female pushing her ovipositor into the bud from the apex and right down to what would be the eye of the flower, and there deposits her eggs. They are imbedded in the living substance, and erineum is produced on what would be the petals of the flower. These eggs hatch out in a few days; but the mites are enclosed, and in

growing they form somewhat large tuhes, not unlike erineum, but stouter, shorter, and blunt-ended, and from these the mites emerge. The tubes are easily seen, and heing hairy on the outside are readily distinguished from the erineum, which is not hairy on the surfaces. The mites at once commence depositing "buds," which are almost as much in diameter as the four-legged mites which shed them. These "huds" produce more four-legged mites, and all, or such as survive—for they have many enemies when they become full fed—pass from this into the six and eight-legged stages, and it is the four-legged mites that do all the mischief; or rather they do the work mapped out for them by the perfect mite, which deposits its eggs where the succeeding generation will find the needful food ready for its sustenance.

What hecomes of the mites after they leave the Chrysanthemum buds I do not know, but this I do know, they will return at the appointed time of breeding and deposit eggs in the flower buds then formed. This is seldom deferred beyond July, and as regards Chrysanthemums is usually restricted to the king or crown buds, though the side buds are occasionally infected. There is one peculiarity about this mite which deserves notice, it does not, like other hud mites, cause the buds attacked to become abnormally large, and their presence cannot be detected by any external sign until the mischief is done—that is by the buds not swelling as they ought.

The only thing likely to be of any use is to syringe the plants with bisulphide of calcium (see page 223), 1 pint to 12 gallons of water, immediately before or directly the Chrysanthemum buds appear, and repeat occasionally to August. Dusting with tobacco powder would also act as a preventive. The only remedy is to cut off the early crown buds and rely on side huds, which is very plainly set forth in "Chrysanthemums and their Culture," by Mr. E. Molyneux; but this has no regard to mites, only the practice cuts short their career, as the four-legged mites must perish in the decapitated buds, and they certainly cannot leave them and enter others. The best thing is to make sure and hurn every crown bud removed, also cut off every "deaf" bud without delay and serve it the same.

Some people like the large white Daisies, Chrysanthemum Leucanthemum maximum. When the plants have the buds "deaf"—that is, cease to swell and develop flowers, cut off all such and burn them. Pursue this with all the huds appearing in a similar condition, and it will he found that the plants will produce flowers as well as leaves.—G. ABBEY.

EARLY FLOWERING CHRYSANTHEMUMS.

In my former note I am afraid I did not make my meaning clear, for I do not want to see better things than Chrysanthemums at a show where they are supposed to form a leading feature. It was solely for the purpose of secing the display of early Chrysanthemums that I went to the Aquarium, but they were unquestionably far less attractive than in previous years. The fault, if there be one, scarcely lies with the N.C.S., but rather with those who have sung the praises of the early section. So much of late years has been said and written about this new race and the value of them for outdoor decoration, and I know not what else beside, that any true lover of the Chrysanthemum must have shared my feelings of disappointment at the very few varieties of modern introduction that were staged on the occasion of a show where one naturally expects to see a first-class assortment of the best new flowers.

From what I know of the Chrysanthemum circle I should say there is a very small percentage of the members of the National Society who are ardent admirers of early varieties, and I question whether they are wanted. The November Chrysanthemum makes itself beloved on its own merits, the early kinds appear to require being subsidized. If that be so they are not wanted, and the sooner they cease to exist the better. This appears to me to be the more strongly manifest when such dull, colourless blooms are placed in striking contrast with Dahlias and Gladioli. No flower can hope to retain its hold on the public if it has to be propped up with pecuniary assistance; it must assert its own inherent value, it must be loved for itself alone, for its form, its colour, its beauty, and usefulness. Herein lies the difference between the early and the November Chrysanthemums, the latter having all the qualities that appeal to the affections of the flower loving community, chief of all perhaps being its seasonableness. At the time of year when it comes to us in all its fulness it is indeed a thing of beauty, if not a joy for ever, and has many thousands of admirers.—P.

EASTERN LILIES.

THE Duchess of Sutherland, who is an earnest amateur horticulturist, writes me to say that the Japanese, Indian, and Levantine Lilies which she planted at my suggestion at Trentham last winter have proved a gratifying success, and that Her Grace intends to give them a trial at Dunrobin Castle, Sutherland, where she is at present residing. Among those which have succeeded admirably at Trentham, where I saw them recently, are Liliums auratum, longiflorum, speciosum, Kraetzeri, Wallacei, Kramerianum or "Krameri," and giganteum cordifolium, of which the last mentioned, the emperor of Liliums, is grown under glass, though this is not requisite to ensure its success. Lilies have been at least three weeks earlier than usual this year, but, though in many instances they flowered splendidly, they did not grow to their average dimensions for want of rain.

In my own garden L. davuricum, also called umbellatum, flowered

in May; the beautiful Madonna Lily, Lilium candidum, in June; longiflorum and giganteum early in July, closely followed by the majestic auratums, the later flowering varieties of which have now the harmonious companionship of the exquisitely formed and delicately fragrant Lilium speciosum. The cultivator of Eastern Lillies is, manifestly, to be envied; for if even moderately successful he may have from the period of the Narcissus to that of the latest autumnal Chrysanthemum one long, continuous, and infinitely varied bloom. Their reign is, therefore, as impressive in its duration as that of the Rose. The infamous sparrow has, in my garden, occasionally attacked the Gelden-rayed Japanese Lily, and destroyed its noble buds when preparing to expand, but that I may add was before the adjoining cornfields were ready for his always unwelcome incursions, since which period he has left my Liliums alone.—DAVID R. WILLIAMSON.

LILIUMS FROM COLCHESTER.

WE send Lily blooms mostly from plants growing out of doors, viz., L. speciosum Kraetzeri, L. s. Melpomene, L. s. macrantha, and L. tigrinum Fortunei. Owing to the drought Lilies have had a bad time, the flower spikes are short and the substance of the blooms thin where grown out of doors; but as regards pot culture where moisture has been freely given it is quite different, and the blooms and spikes this year are very good. We also have included bloom of Lilium neilgherrense and L. Henryi. The former Lily has flowered with us very freely this year, but requires the aid of glass both to start it and finish its growth. Imported bulbs arriving in a shrivelled, poor condition late in the spring, plumped up rapidly, and to our surprise grew to the flowering stage much better than could have been expected, showing that it is really a very vigorous Lily under proper treatment; its scent is peculiarly like honey. L. Henryi has been grown by us both in pots out of doors and in the open ground. It is a grand grower. We received our bulbs from China in the middle of March last; they soon hegan to stir, the growths appeared some six weeks later than those established at Kew, and are now in full flower, those at Kew being over some six weeks since. It has evidently a hardy constitution, and roots very freely, has dark green foliage and numerous flowers. It is from these points and from its novel colour a grand Lily for the hybridiser. Two points about this new form seem not to have been brought forward—its broad beautiful dark green central axis, translucent like deep sea water; second, the number of large processes of an orange yellow colour which fringe these green axes. It is a beautiful flower for ladies to wear, specially for those of a dark complexion, or a couple of blooms well backed by the foliage of the scented-leaved Pelargoniums are very decorative in a room. We feel convinced that this Lily will become a great favourite with the fair sex.

We are hound to express our surprise on reading the paragraph on page 265 reflecting on ourselves in copying your illustration without permission. So far from that being correct, we purchased the block from your office, and as no stipulation was made as to the use to which it might be put we thought, and still think, we had a perfect right to use the block in our catalogue.—WALLACE & Co.

[The flowers referred to were beautiful. Many of the buds expanded on being placed in water, and others are still opening, showing the great value of Liliums as cut flowers for decorative purposes. In reference to the illustration Messrs. Wallace & Co. had the undoubted right, under the circumstances, to use the block in their catalogue. Had we known they had purchased it the paragraph would not have been written, and it may now be considered as withdrawn. The block was sold in the publishing department without the fact being made known to the Editor—a purely accidental omission that occurred during a moment of pressure in business. Our rule is only to supply blocks to the owners or exhibitors of the flowers illustrated, and it is not departed from except by special arrangement equitable to all parties concerned in their reproduction.]

GRAPES SHANKING.

MR. RICHARDSON'S article on this subject (page 238, September 14th) is in some respects a remarkable one.

- 1, He says about a dozen bunches left unthinned in 1892 had not a shanked berry in them. Nothing is said about the variety left unthinned, nor anything stated as to the condition of the thinned bunches in that year; but it is assumed that his subsequent statement—namely, "In previous years there was not a bunch but was more or less affected by the disease" applies to the thinned bunches in 1892. This being so, it is clear that the thinning was considered in 1892 to be the cause of the shanking, hence the decision to leave the whole crop unthinned in 1893.
- 2, In anticipation of the prospective heavy crop in 1893 measures were taken in advance for its support. A heavy dressing of fresh cow manure was given to the borders in the early part of November. Inside it could only benefit to the extent of the washings from it by artificial watering. Outside there would be washings by rains, and the consequent enrichment of the soil. The removal of the November dressing of cow manure in February, and the supply of another dressing then, left till the first week in May, is a method of enriching the soil with one of the most soapy, close, and retentive of manures in the winter season. It is an old and bad practice.

3, The feeding twice a week with the undiluted drainings of the

cowshed from the first week in May until the Grapes began colouring, could not have other than a good effect, especially as the season of 1893 has been the hottest and driest on record. Your correspondent was singularly fortunate in having such an abundant supply of cowshed drainings at a time when most cows were at grass and the tanks empty. The applications appear to have suited the Vines admirably under the conditions prevailing in 1893—a broiling sun, a parched soil, and an arid atmosphere; for the result was "A magnificent crop of good bunches with medium sized berries (no puny stoneless ones), excellent in flavour,

but as might be expected, deficient in colour."

"Poverty," says Mr. Richardson, "is the cause of shanking in Grapes." Mr. Barron in "Vines and Vine Culture," gives overcropping as the "cause of shanking to a very serious extent," and Mr. Richardson's Grapes were so plentiful that they were deficient in colour. With the Grapes unthinned there is more danger of poverty than when they are thinned. Of course Mr. Richardson means poverty of soil, but Mr. Barron includes "rich materials" as one of the causes of shanking. Though a believer in "muck," I am sorry to say that where it is most used shanking is most rampant, and Mr. Richarson's experiment only proves the importance of feeding the Vines when the greatest strain is put upon them by the crops.

As to the cause of shanking I must say that it has so far baffled both cultivators and scientists. The alleged causes are as opposed to each other as the poles of the earth, that is, shanking occurs in Grapcs under conditions diametrically opposite to the assumed cause. Let us notice a

few of them.

Overcropping the Vines.—Mr. Richardson has shown that Vines with the Grapes unthinned, and a crop so heavy as not to colour well, there was less snanking than when the berries were thinned, and the seeds much less in number. In a vinery where the Vines are seen carrying a crop of Black Hamburgh Grapes an black as jet, and a weight of fruit equal to 1 lb. per foot run of rod, scarcely a shanked berry is to be found, but in one adjoining, and with the Vines carrying a bunch of Grapes here and there, not only small branchlets, but whole shoulders, and in some cases whole bunches have to be cut away because the

Grapes are shanked. Weakness.—This must be distinguished from poorness of soil, for Vines against houses, and with the bunches unthinned, like Mr. Richardson's, often produce enormous crops of Currant-like unshanked Grapes, and this is allowed to go on until the Vines become so exhausted as to yield nothing but leaves and tendrils. Such Vines with the shoots properly thinned and pruned, also fed at the roots with house slops, would bear excellent fruit if the bunches and berries were duly thinned. But this is not the weakness alluded to as conducive of shanking, for what is meant is a puny condition of the Vines resulting from early forcing or heavy cropping in consecutive years, even where the borders are rich, yet we have growths tendril like and small bunches with a large percentage of shanked berries. Border renovation, a year's rest and freer growth will generally insure better crops. But the opposite of weakness—that is, grossness, or Vines with soft long-jointed shoots, leaves like Rhubarb, and lank loose bunches, is also given as one of the causes of shanked berries, and the remedy propounded is border renova-

Restriction .- Too close stopping or poverty of foliage and consequently indifferent root action is presumed to favour the dwindling of the bunches and cause the berries to shank. The remedy for this is alleged to consist in allowing the Vines to make more growth and to prune less Vines, however, on the extension system often go wrong—that is, they produce Grapes that shank in some cases to the extent of onethird of the crop. The preventive for shanking in this case is assumed to be found in pinching. This shows the falsity of extremes. to be found in pinching.

Checks to Growth.—One of these, prejudged to promote shanking, is to remove a large quantity of foliage at a time and at distant intervals. This, of course, is a bad practice; but the fact remains that at the opposite pole is seen Vines that have never had removed from them more growths than can be carried away at one time from a large vinery in the attendant's apron, with a number of red sour berries in the otherwise well finished bunches when the Grapes are ripe. It is difficult to understand why outdoor Vines with the shoots cut back considerably just before the Grapes commence ripening have few shanked berries, while Vines so treated under glass have a large number of shanked Grapes.

Chills.—Allowing the temperature to rise considerably in a vinery and then admit air so as to reduce it several degrees is said to produce rust on tender Grapes and shanking when they ought to ripen. The other side of the question is, that however careful the cultivator may be about ventilation, the Grapes often shank badly.

Rich Borders.—When the carcases of animals were buried in Vine borders the Grapes were said to have been wonderfully fine in some cases and in others that the Vines absolutely refused to grow. About shanking under such conditions the records are mute, and I have no experience. Nevertheless rich borders are alleged to induce shanking in Grapes, but there is a difference as regards richness in Vine borders. Some are composed of material which settles into a close soapy mass, and the Grapes produced by the Vines planted therein sometimes shank in the stems of the bunches. Others are formed of rich material, with enough gritty and calcareous substances to render them porous and swect, yet the Grapes borne by healthy Vines growing in them are shanked more or less. Mr. Richardson tells us that the cause of shanking is poverty of soil. Grapes certainly shank when the Vines are grown in poor soil, perhaps one berry in a thousand as compared with those growing in rich soil.

Excessive Dryness at the Roots.—Mr. Barron gives this as paralysing to the young roots and a cause of shanking, for deluging with water afterwards destroys the roots. I presume every gardener has a copy of Vines and Vine Culture, if not, he ought to procure one, for the illustrations of the Grapes—almost every variety—certainly all worth growing, with the descriptions, are worth double the money (5s.). But the fact remains that Vines receiving 72 inches of water or equal to that of rainfall, have the berries shanked ten times worse than those of Vines growing in a gravelly soil receiving only 24 inches of rain direct from the clouds.

Sodden and Sour Svil.-Whether the Vines are in pots or planted in borders this condition at the roots results in shanking in the Grapes. There is no question about that, nor is there any of Grapes also shanking when the roots of the Vines are in the most favourable circumstances as regards soil sanitation. It is a matter of degree, for it is not difficult to find shanked berries in the best examples of certain varieties, to wit Frontignans, Black Muscat, Muscat of Alexandria, and even in Black

Hamburgh.

Cold Borders.—Forty years ago there were ten outside Vine borders to one even partly within the houses. There was no more shanking in those days than at the present time. Mr. Barron mentions cold subsoils, of course, with the roots in them, as a source of shanking, and it is quite true, nevertheless he recommends outside borders (and I agree with him) for summer Grapes; but I have seen Grapes ripe in March on Vines over Pines with the roots entirely in an outside border, and covered with a coating of the soapiest manure. It would have delighted Mr. Richardson to have seen it, for there were only "a few shanked berries here and there." That is one side of the picture, the other is That is one side of the picture, the other is Muscat of Alexandria Grapes shanking badly when the roots of the Vines are confined to inside borders. Mr. Richardson has only a few shanked berries and no puny stoneless ones with the roots of the Vines partly in and partly outside the house. The case is a hopeless one— Grapes will shank.

Bad Management.—This includes errors in ventilation, syringing, watering, temperature, disbudding, stopping, thinning, cropping, feeding,

unfortunately Grapes shank under the best treatment.

Fungal and Insect Attacks.—Mildew infesting the growths and berries, and the destruction of the foliage by red spider, also scale and to induce shanking in Grapes. They may; the mealy bug, are said to induce shanking in Grapes. They may; the facts are as positive in the opposite direction, for I have seen outdoor Grapes white with mildew in June with Grapes as black as jet and covered with a blue bloom in September, except where rusted by the sulphur in destroying the mildew. A similar thing occurred in a house, the Grapes ripening but much rusted. There was nothing remarkable in either case as regards shanking. Grapes may ripen off red, and even shrivel when red spider has exhausted the foliage; even scorched Vines shank less, if anything, than Vines do in some cases with flimsy foliage, and scale and mealy bug in no way contribute to shanking. I have seen whole houses of Grapes, every bunch of which had to be syringed before sending the Grapes to table; but the scissors had not to be employed to cut out red, sour, shanked berries.

Outdoor Grapes.—These are found to shank less than the same

varieties indoors; yet shanked berries are found both on thinned and unthinned bunches, on heavily cropped Vines and on those carrying only a few bunches. It is hardly necessary to say that shanked Grapes are common on Vines under glass.

Time.—Shanking is generally confined to the period when the Grapes begin changing colour. Sometimes it is only a berry or two, in extreme cases it is a whole bunch; generally one or more of the branchlets or shoulders, or parts of them that shank. One Vine has few, its neighbour of the same variety has many shanked berries; some are red and sour, others are black and not ill-flavoured. It is similar with white Grapes. Some of the shanked berries shrivel, remain green, and are ill-favoured, while some retain their plumpness, attain a high colour, and are exquisitely flavoured, as found on some bunches of Muscat of Alexandria It is not a question as to when the shanking occurs, for it does so both before and after the Grapes are ripe, also after they have been cut, bottled, and placed in the Grape room.

Thirteen causes of shanking have been given, and still the real cause of the evil is as great a mystery as ever. All I know about shanking is that, like every other disease, it is induced by certain favouring climatic, conitary and cultural conditions. This being a like the following that the conditions of the cond sanitary, and cultural conditions. This being so, it follows that it is to a great extent preventible by careful cultivation. Some varieties being more subject to it than others may be rejected, as is recommended in the case of Apples and Pears to avoid canker; but this is an admission of being dead beat, and is analogous to killing a whole herd of cattle because one or two are afflicted with anthrax. Who can dispense with because one or two are afflicted with anthrax. Black Hamburgh and Muscat of Alexandria? Both are at the head of their classes in quality and in liability to shanking, but they have been to a great extent superseded by the thick-skinned varieties, less subject to the evil. Still the varieties first named are grown in proper structures, well provided with means for ventilation and heating, well constructed borders of sound material, and good cultivation all round, without many shanked berries.

Notwithstanding all that has been advanced in support of shanking being a constitutional and heredital disease, the fact remains that it is of an organic nature, and as such has its rise in the morbidity of the subject. That, however, cannot give rise to any living organism; it is caused by and owes its origin to a micro-organism, which, like all life, is dependent for its existence on a parental germ. -G. ABBEY.

THE ASHFORD VINERIES, FORDINGBRIDGE.

JUST as the seeing of a place that has a reputation, and yet is indifferently cared for, brings the visitor disappointment, so does a visit to a place where little is looked for and much that is good found afford exceeding satisfaction. I have been into many market-growing establishments about London, and have usually found that everything about them was made very secondary to tidiness and general excellence; consequently when recently I called at the Fordingbridge Vineries I looked for nothing better, but was exceedingly pleased to find a large number of houses in perfect condition, the whole place neat and clean, and the culture of Vines, Tomatoes, and Chrysanthemums, for these are just now the chief objects of culture, of the very best. Perhaps some of this is due to the fact that Mr. Stephen Castle, who is the Manager, and has had full control for several years, is at once a modest man, who boasts nothing, has some garden taste as well as much skill, and is certainly a capital cultivator. It may seem odd that what is a small town of such excellent houses should be dropped down in so remote a part of the country. The vineries are the property of a well known Jersey firm, Messrs. A. & J. Quartier, who also have an extensive corn business at Fording bridge. On the other hand, it would seem as if soil and situation were in these days of far more consequence than place and distance, for the railways render locality of small moment, and it seems as easy, as is found in practice, to send products to London, Manchester, or Edinburgh, as to Bournemouth, Plymouth, or Exeter. The vineries are close to the railway station, and in that respect, whether in getting in coal, for Mr. Castle believes only in anthracite, or for sending away produce, is most convenient.

Looked at from the clevated railway a little towards Wimborne the entire body of glass is presented in the form of a large triangle, the acute angular point being closest to the spectator, whilst in the remote background are Mr. Castle's and some of his assistants' residences. Just by these there is yet space to erect another long, broad span house, and then in a meadow below there is reserved space for the addition of some ten or twelve more large houses, and these no doubt will be erected in a few years. For the purpose of examining the contents of these structures we start from the manager's house, and enter a huge lean-to that fronts to the north-east of the other houses. This is 200 feet by 18 feet, and is in three equal divisions. The first two are planted with Gros Colman, the end one of which is the latest. Here at the time of my visit the berries were just showing a little colour, whilst in the next division the colouring was much more advanced. These represent the latest of the five market Grapes grown. The Vines are planted close to the front, and at only 2 feet apart. There are twenty-three Vines in the first division and thirty in the second, a portion of the first being otherwise occupied. Every Vinc is carrying a tremendously heavy crop of good sized bunches, and the berries when ripe will be fully up to the usual dimensions. Each rod is expected to give 40 lbs. of Grapes; whilst those in the first division will be cut in January, those in the other will be cleared by Christmas. The third division is planted with Black Alicante, and there are twenty-nine rods. Here, too, there is a great crop, although not the same weight as in the other divisions. Grapes are, however, nearly finished, and will be excellent in every respect, the average weight per rod being rather over 30 lbs.

It is worth noting that for these Vines, as indeed all over the place, no very special preparation has been made. The borders consist of the ordinary soil deeply trenched, and it is naturally drained. It is very firm, and seems to have very enduring nature—indeed, it must have good natural properties to carry such crops of Grapes year after year. There is very little of top-dressing with animal manure, as it does not seem to be too accessible; about 3 feet wide, close to the Vines, alone is thinly dressed. The chief reliance seems to be on the patent silicate manure, which Mr. Castle largely uses for top-dressing, and which he regards as most valuable for Vines. I may mention here that for all his Muscat Vines he adds a moderate proportion of sand to the borders, and also gives occasional dressings of it, as well as of the manure.

The next house, running at a slight angle from the one described, is a fine span 210 feet long and 30 feet wide. This, too, is in three divisions and was planted with Vines so recently as 1891. In the first division on the north side twenty-two Alicantes are planted 3 feet apart, each one carrying from ten to twelve well-coloured bunches. On the south side are the same number of Gros Colman, each one heavily fruited. Then on either side of the centre walk, and at 6 teet apart, there are planted on the south side Alicantes, and on the other Gros Colman, so that some of each sort are on each side of the house. These are trained as vertical cordons, each carrying on an average twelve to fourteen bunches, and not less than 20 lbs. weight. Tomatoes in pots are run up between the Vines. The second division is planted exclusively with Muscats, but the crop had been cut. Into the border four loads of sand had been worked. Mr. Castle speaks very highly of the Canon Hall Muscat of which there are several Vines, specially liking its full berries, stout dark leafage and wood and general productiveness.

The third and lower division is planted entirely with Gros Colman, twenty-four on cach side, and twenty-four down the centre for erect training, making seventy-two in all. The berries on the north side have much the best colour because the sun caught them obliquely through the glass above the Vines on the opposite side. This fact shows in getting colour into this Grape the importance of ample sunlight. This division was planted towards the end of May, 1891, each Vine now catrying a heavy crop up some 6 feet of rod.

*Close to the end of this fine vinery commences the smaller houses of

the large triangle of glass. Here is a block of three, each 12 feet wide respectively, of 30, 40, and 50 feet long. The Vines in the first house are Black Hamburghs, planted 3 feet apart, and are two years established. They run to the apex on each side, and have given a good crop. The borders are 5 feet wide, and only 9 inches deep, as being They run to the apex on each side, and have given a good built for Cucumbers, pipes run along beneath. The second house is planted partly with Hamburghs, partly Gros Maroc, in the same way, but the crop has been cut. The third house is planted with Muscat of Alexandria; the return pipe in the chamber beneath the border being found most helpful in finishing the berries. The Vines here are three years planted, and carry a fine crop. Then follow three span houses, each 18 feet wide, and respectively 70, 80, and 90 feet long. The centre gutters of these rest on brick piers, so that the houses are all, so far, open one to the other. The plan, however, is productive of cold draughts, and is not desirable. One range of pipes is made partly to heat two houses. The first house is full of Gros Colman, chiefly planted form made about 0 foot large and 2 foot spect containing a heart four years, rods about 9 feet long and 3 feet apart, carrying a heavy crop. A few Muscats planted by mistake are to be worked with Gros Marga for a few Vines of that variety do records her well because in Maroc, for a few Vines of that variety do remarkably well here, and in all cases the soil seems to impart excellent flavour to the fruit, perhaps due to some extent to absence of gross feeding. In the second house the Vines are chiefly Alicantes, the rods laden with fine bunches, and richly coloured. In the third house Muscat of Alexandria and Gros Colman are planted alternately. The greater part of the crop here, also a very fine one, has been cut.

Next comes a block of houses 20 feet wide, ranging in length from 120 to 160 feet. The first house is planted on the west side with Muscat of Alexandria and Gros Colman alternately, all the other side being the latter sort only. The Vines are four years old, and the crop is indeed a splendid one, presenting a grand sight. The Grapes are cut during November and December. The next house is planted entirely with Gros Colman, two years old, fruiting about 7 feet lengths, each rod having from nine to eleven bunches. There are in this house 100 Vines at 3 feet apart. In the third house of this group Black Hamburgh Vines have been planted recently for early forcing. Tomatoes otherwise fill the house, these being planted crosswise in rows 3 feet apart and are vertically trained. The crop has been a heavy one, and fruit will be furnished if desired till the end of October. The chief varieties are Hackwood Park, Sutton's Perfection, Challenger, and Webb's Regina, one of the larger Apple-shaped sorts, of which Mr. Castle speaks in the highest terms. The fourth house is also recently planted with Black Hamburghs, and in it immenses numbers of Tomate plants have been as

and in it immense numbers of Tomato plants have been grown.

Lastly is a huge house, 34 feet wide by 160 feet, the first division of which was planted last spring with Peach and Nectarine trees. The second and third divisions were planted with Gros Maroc last April, and will soon be in a productive condition. This house, too, has been planted with Tomatoes, and amongst them are Conference, Ham Green Favourite, and Vick's Criterion. This completes the record of the glass houses at the Ashford Vineries, and presents a total length of 1530 fcet a goodly area of glass to be met with so far from London. Mr. Castle has long been known by his writings, and very often by the fine examples he has shown, as an authority on Grape culture, and this unbiassed record of what I have seen of his work will, I am surc, carry conviction that he is fully entitled to all the honour of such a position. -A. D.

LONDON TREES.

THE following correspondence regarding London trees appeared recently in The Times:

BEFORE parting with the memorable summertide of 1893, it may not be profitless to observe its effect upon trees, so essential to the beauty and health of the metropolis. They afford the one redeeming feature to an otherwise ugly town. Some years ago I brought upon myself a good deal of adverse criticism by quoting Leigh Hunt's saying that it was hard to find a single street in London from some part of which a tree was not visible. I only know of two—viz., Savile Row and a street parallel with Berners Street.

London trees have two adverse influences to resist—coal smoke and heat reflected from miles of brick and stonework. The effect of the latter is so clearly marked upon several species at the present moment that the lesson ought not to be neglected by the Office of Works and by those in charge of squares and gardens, for, although the heat has been greatly excessive this year, trees in a town are always exposed to greater summer heat than those in the country.

The trees which have suffered most are one native species—the Wych Elm, and two exotic species—the Horse Chestnut and the Lime. The condition in which these are now and have been for some weeks past ought to convince us of their unsuitability for urban planting. Many of them are entirely leafless; others retain but a sere remnant of summer clothing.

The Plane, for which we shall soon have to borrow the title of a humbler green thing and call it "London Pride," has stood the trial fairly well, for, although it has shed half its leaves, the other half remain and are still fresh and verdant. By a popular mistake this tree is called the Western or Occidental Plane. It is not so, but an Eastern European and Asiatic species (Platanus acerifolius), and may be distinguished from the American P. occidentalis by bearing two or more seed vessels on the fruitstalk instead of one.

Aspens and Poplars have suffered not at all, and should be more

largely planted in London. By a peculiar formation of the leafstalk, which is flattened midway, they are specially provided with a mechanical means of protection against heat. The leaves hang vertically, and possess glands on both surfaces, whereas Oak, Beech, Chestnut, &c., have glands only on the under surface.

Ailantus glandulosa, the Tree of the Gods, is in splendid foliage, and, if more care were taken to keep it in shape in its early years, would soon

prove one of the surest ornaments of our streets.

But the tree to which I wish to call special attention as invaluable for towns is what is commonly called the Acacia. It is not an Acacia at all, being of the Pea flower tribe; its scientific name is Robinia pseudo-Acacia. Let anyone compare the fine specimen standing at the corner of Lord Sefton's house in Belgrave Square, or a group of young ones in the Green Park, near the Wellington Arch, with trees of other kinds around, and he cannot fail to recognise in this species one which, for beauty of form or freshness of verdure, cannot be excelled for planting in towns. Ulmus campestris, called the English Elm because it is not English, has kept its foliage fairly well, but it is dull and discoloured.—HERBERT MAXWELL.

SIR HERBERT MAXWELL does well in calling attention to the Ailantus glandulosa in his remarks on London trees. It is one of the very best trees for the soil and climate of London, and will in time grow to the height of 40 feet or 50 feet. So vigorous is the growth in a young state that it will often make a shoot of 6 feet in a single year. The leaves are large and handsome, 3 feet or more in length, with a thick midrib, on each side of which are ranged in pairs some twenty or thirty lance-shaped leaflets. I have a specimen of this tree in my garden nearly 50 feet high, which is the admiration of everyone who sees it. When the late Major M'Kenzie was about to plant the trees on the Thames Embankment I remember discussing with him the merits of this tree for that position. It was, however, decided, properly I think, that the beautiful but massive foliage would be torn and disfigured by the strong currents of wind often prevalent there. In fairly sheltered positions no tree is handsomer or more appropriate for cities and large towns, as it is very hardy and will grow anywhere. Many trees which flourished in London some thirty or more years ago no longer thrive there, owing to the increased volumes of smoke and various noxious gases; but there are still many trees and shrubs, which, owing I believe principally to the structure of their leaves, seem to set these influences at defiance, and the Ailantus is one of the most valuable of them. Planes, Poplars, and Robinias (the latter usually called Acacias) are proved London trees, and there are many varieties of each far preferable to the old-fashioned and beautiful but unsuitable English and foreign trees still injudiciously planted.—WILLIAM PAUL, Waltham Cross, Herts.

MAY I add a word of caution to Sir Herbert Maxwell's praise of the Ailantus as a London tree? The foliage has all the beauty and endurance he claims; but, to use the words of an American authority, Mr. F. B. Hough, "the male flowers have a nauseating odour that renders this tree undesirable for cultivation near dwellings."

I think I am right in adding that not many years since most of the Ailantus trees in New York were grubbed up on account of this offensive character. It is a tree also to be handled with care on account of the acrid juice of its bark, which has been known to caused poisoned hands among woodmen and gardeners —J. L. P., Marlborough.

TRIDAX BICOLOR ROSEA.

A NORTHERN correspondent sends us a few blooms of this pretty late flowering plant, and remarks that the yellow-flowered Compositæ are so numerous in late summer and autumn that it is quite a relief to obtain any additions to the family in which the flower heads are of some other tint. We think so too, and the plant to which attention is called is by no means familiar in gardens. When in bloom it is very attractive, and is worthy of a place with other border plants. As will be seen by referring to the illustration (fig. 42), the flower heads are of moderate size and neat shape, white with a strong suffusion of deep clear rose—a peculiarly bright and pleasing tint. They are freely produced. The plant is compact, of moderate height, and of easy culture.

APPLES AND PEARS AT WOODHALL, WEST NORFOLK.

"WOODHALL," a very ancient mansion, is said by Kelly in his Directory of Norfolk to have been "formerly one of the seats of the Abbots of Ramsey, to whom the estate belonged before the dissolution of the Monastery in 1537." It is now the property of Major Stocks, D.L. and J.P., by whom it has been much enlarged and in every way greatly improved. I do not purpose, however, now to take up space in the Journal by a description of this fine old place other than as it relates to the above-named fruits.

Mr. Lewendon, the gardener, is an experienced and successful fruit cultivator, both outdoors and under glass. Heavy crops of Grapes of the finest quality and finish, Peach and Nectarine trees in splendid condition, perfectly clean with fine foliage, well ripened wood on triple buds boldly developed at nearly every leaf, show his skill in growing fruits under glass; but this skill is perhaps still more strikingly shown

outside by trained trees on walls, bush and pyramid trees in gardens, and free standards in the orchard. All alike arc, or have been, carrying fine crops of fruit of the largest size and finest quality.

Here may be seen carried out most effectually the rational methods of pruning advocated by many horticultural writers and lecturers—viz., no lopping off of large limbs (mutilating, not pruning), but judicious

FIG. 42.—TRIDAX BICOLOR ROSEA.

thinning out of the smaller branches annually through all the free orchard trees, so as to admit a full amount of light and air freely through all their parts. This practice, combined with due attention to cleaning the trees annually by lime dressings in the winter and feeding their roots as required, results in the good supply of fruit of the finest quality. Some horizontal trained Pear trees, covering one side of a long range of stables and carriage houses, are pictures of health, fruitfulness, and good management. The common error one meets with in trees of this class is overcrowding both of the horizontal branches and of the spur growths thereon, but here no overcrowding is permitted either in trained trees,

free standards, or pruned bushes. In pruning pyramids and bushes, Mr. Lewendon says he prefers "to give them their head"—that is, he leaves the leading growths a foot or more in length, but keeps each branch

quite a foot distant from its neighbour.

A considerable portion of the fruit had been gathered on the occasion of my visit, and a peep into his fruit room was a treat not soon to be A number of Warner's King Apples covering a long rack, forgotten. were the finest I have yet seen of that variety. The fruits taken throughout, as gathered, I was told, averaged 18 ozs. each, and one specimen when placed on the scales bumped them down at $1\frac{1}{2}$ lb. Other varieties so large and fine as to be almost out of character were Gloria Mundi (averaging 1 lb. each), Blenheim Orange, Lord Suffield, Ribston Pippin, King of the Pippins, Cox's Orange Pippin, Kentish Fillbasket, Lady Henniker (a favourite with Mr. Lewendon), New Hawthornden, Sturmer Pippin and Worcester Pearmain. Bismarck, Cellini, Small's Admirable, Lane's Prince Albert and Bramley's Seedling were also very good indeed.

Amongst Pears his finest and best are Maréchal la Cour (a variety which succeeds remarkably well in the eastern counties), Dorothy Royal, Zepherin Grégoire, Pitmaston Duchess, Durondeau, Forelle (very handsome), Beurré Diel, Beurré Clairgeau, Beurré Rancc, Beurré d'Aremberg, Marie Louise and Winter Nelis; very good also were Autumn Bergamot, Williams' Bon Chrêtien, Glou Morçeau, Passe

Colmar, Thompson's and Josephine de Malines.

Passing from Woodhall, I find in many parts of Norfolk grand old trees alike trees of the fine Apple Ecklinville Seciling. Young and old trees alike are laden with fruit of large size, clear skins, and of such colour as one only expects to see upon fruit grown under the sunny skies of Kent. a well tried variety for the market grower this is hard to excel in the

county.

In many orchards I also find large trees of Wyken Pippin heavily laden The trees as a rule bear every second year, the trees needing with fruit. a season to recuperate after perfecting such heavy crops as they are now I am surprised to find no young trees planted of this delicious Christmastide Apple. The tree is a vigorous grower everywhere, perfectly free from canker, and makes a large spreading head. Of few varietics only can it be said they are free from canker in this generally flat, low-lying, badly drained county, which seems to produce forest trees and pheasants far better than high class fruits.—W. K. W., Leeturer in Horticulture to the Norfolk County Council.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 26TH.

THIS meeting brought a very effective display of autumn flowers-Dahlias being very prominent, Orchids, fruit, and vegetables.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Rev. W. Wilks, Dr. Hogg, and Messrs. John Lee, G. Bunyard, J. Cheal, A. H. Pearson, G. Goldsmith, G. Taber, T. J. Saltmarsh, W. Warren, J. Smith, H. Balderson, J. Hudson, G. Wythes, W. Iggulden,

G. Reynolds, G. Sage, A. J. Laing, A. Dean, and J. Wright. Mr. E. Molyneux, The Gardens, Swanmore Park, Bishop's Waltham,

sent a magnificent dish of the American Apple Wealthy. large, round, inclining to ovate; greenish yellow, almost entirely covered with broken crimson stripes. Very handsome, symmetrical, and as tender as a Pear. Considerable discussion arose relative to the growth and bearing habit of the trees, some of the members expressing their strong disapproval of the variety in those respects, while others had found the trees quite satisfactory. Eventually an award of merit was granted by a majority of three votes.

Sir John H. H. Amory, Bart. (Mr. Grigor, gardener), sent a new Melon named Maximus, cut from a plant in a pot. Fruit oval, very large indeed, but like many other large late fruits wanting in quality, and no award was made. Mr. J. Lye sent from Clyffe Hall, Market Lavington, a fruit of his new Melon Lye's Exquisite, a medium-sized green flesh,

but over-ripe. Probably a good Melon when in condition early in the season, and the Committee desired to see it next summer.

Sir E. Loder (gardener, Mr. G. Goldsmith), Leonardslee, Horsham, sent a dish of Pomegranates, very large, 3 inches in diameter, grown against a wall in the open air. They were not ripe (vote of thanks). Plenty of fine ripe imported Pomegranates can be bought from barrows in the London streets at 1d. each. Mr. J. Duncan sent ripe Grapes grown in the open air at 45, Amherst Park, Stamford Hill, London (vote of thanks). A similar mark of recognition was accorded to Mr. Wm. Palmer, who sent from Andover a dish of Duke of Albany Peas grown from seed ripened from an early crop in the summer and sown on

July 15th.

The Earl of Cork and Orrery, Marston House, Frome (Mr. W. Iggulden, gardener), sent thirty dishes of splendid Pears, mostly grown by old trees on Pear stocks in clay soil. A silver Knightian medal was unanimously recommended for the collection, also a bronze medal for an unusually fine dish of Doyenné de Comice. Besides the variety named grand dishes of Van Mons Leon le Clerc, General Todtleben, Glou Morçeau, Easter Beurré, Beurré Sterckmans, Pitmaston Duchess and others were staged by Mr. Iggulden, who would like more hot summers at Marston.

Mr. Owen Thomas sent from the Royal Gardens eighteen magnificent Pines and a dish of fruit of Cydonia japonica. The Pines consisted of twelve Queens and six Smooth Cayennes from plants sixteen months old from the sucker. Fruits of the Queens would probably average about 6 lbs. each, while some of the Smooth Cayennes were doubtless

9 lbs. in weight. A silver-gilt Knightian medal was unanimously recommended, and some persons thought that a still higher honour was merited. A vote of thanks was accorded for the Cydonia fruits.

A collection of twenty dishes of Apples and the same of Pears were sent from the gardens of the Dowager Lady Freake, Fulwell Park, Twickenham; very good fruits of popular varieties, and a small silver medal was recommended. A highly creditable exhibit of seven varieties of Onions, six of Apples, six of Plums, and a fine dish of Marie Louise Pears was staged by Mr. John Chinnery, Downton Castle Gardens. produce represented excellent culture, and a silver Banksian medal was A similar honour was voted to Mr. G. Reynolds, Gunnersbury Park Gardens, for twenty splendid Melons, several very large indeed, and all indicating superior culture. J. Nix, Esq., Tilgate Manor, Crawley (gardener, Mr. Dibben), sent twenty-seven dishes of Pears, several of them very good in leed—an excellent representative collection (small silver medal). Messrs. H. Cannell & Sons had a very extensive exhibit of vegetables and fruit, the whole comprising a hundred dishes, only some of the vegetable "dishes" would about fill a bushel basket. Earliest of All Cabbage was represented by neat compact heads, and London Coleworts were very fine. Leeks were blanched to the extent of 9 or 10 inches, and robust plants of Brussels Sprouts were crowded with firm knobs. Potatoes, Carrots, Onions, and most other vegetables in season were included in this representative collection, and a silvergilt medal unanimously recommended.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair);
Messrs. H. Herbst, R. Dean, G. Stevens, C. F. Bause, C. J. Salter, J. D.
Pawle, C. Jeffries, E. Mawley, H. Cannell, A. H. Williams, Charles
Noble, Peter Barr, and Rev. H. H. D'Ombrain.

Messrs. Cheal & Sons set up a very attractive stand of Dahlias,
three bold shields of bloom being flanked by boxes and bunches of

flowers. The central and largest shield was composed of Cactus varieties, prominent amongst which were Delicata, Ernest Cannell, Robert Cannell, and Countess of Radnor. Duchess of York was also noteworthy for its distinct colour, and a new variety called Crawley Gcm, with bright crimson flowers, was much admired (silver Flora medal). Messrs. Keynes, Williams & Co. had a fine display of Dahlias, comprising three large shields of Cactus varieties, in which Kaiserin, pale yellow; Dawn, golden bronze; and Keynerith, the grand scarlet, were prominent; and stands of Show, Cactus, Pompon and single varieties; Delicata, Lady H. Grosvenor, Bertha Mawley, Chancellor, Lady Penzance, and Gloriosa, all Cactus varietics of great merit, were much admired (silver Flora medal).

Mr. R. Dean exhibited Venidium calendulaceum var. multiflorum (Vilmorin), but as only a small pot plant bearing four flowers was shown its value as a pot plant was not strikingly evident. Mr. H. J. Jones sent Fuchsia triphylla carminata alba, the plants being 6 to 8 inches high, in 5-inch pots, bushy and freely flowered. Mr. R. Owen sent a Canna named Comtesse O. de Lestoile and Chrysanthemum Vigilant. G. P. Pierre Harris, Esq., Scads Hill House, Orpington, had a stand of double Dahlias, containing neat bright blooms. Messrs. Pitcher and Manda aroused attention with the fine Datura cornucopia, the flowers of which are white with a faint lilac shading; the reverse of the segments and the tube rich bluish mauve, and with a powerful Auricula fragrance (see below). Messrs. Cannell & Sons contributed a pleasing display of Begonias, the most conspicuous variety being the golden amber single Begonias, the most conspicuous variety being the golden amber single Fashion. The doubles possessed great quality (silver Banksian medal). Mr. A. Waterer showed seedlings of Abies pungens glauca, Andromeda japonica, and Cedrus atlantica glauca (the "Silver Atlas Cedar"). These had been lifted and the roots wrapped in packing material surrounded by mats (silver Flora medal). Mr. C. Turner had some splendid double and Pompon Dahlias, Mrs. Morgan and Norma being very conspicuous among the former (both receiving awards), Captain Boyton, Irene, and Eric amongst the latter. They also had a very promising seedling Cactus named Edith Turner large rich crimson with cerise suffusion Cactus named Edith Turner, large, rich crimson, with cerise suffusion. Mr. T. S. Ware sent a choice collection of new Dahlias, several of which received awards, and are referred to below.

Mr. Arthur Rawlings contributed a large collection of Show and Fancy Dahlias, many leading varieties being in admirable condition (silver Banksian medal). Messrs. J. Laing & Sons were represented by one of their characteristic displays of stove and greenhouse plants, the foliage plants being noteworthy for cleanliness and good colour, and the group was tastefully displayed (silver Flora medal). Mr. B. Ladhams contributed a large and varied display of hardy plants, and he also had some beautiful bunches of his fine Pink Ernest Ladhams. bipinnata was noteworthy amongst the hardy flowers, and so was Heliopsis scabra major, which received an award of merit, and is referred to below (silver Flora medal). Messrs. Veitch & Sons staged several new plants, and three—viz, Nepenthes mixta, Veronica hybrida Purple Queen, and Aglaonema rotundum-were honoured by the Committee

(see below).

The Gladiolus prizes did not bring satisfactory competition. J. C. Tandy, Warkworth, Northumberland, was the only exhibitor in both classes, one being for twelve distinct varieties and the other for twelve British-raised Gandavensis varieties. He was placed first for both stands, and showed all Kelway-raised varieties. Atlas, Corinne, Formosa, Grand Rouge, Enchanteresse, and Pyramide were six of the

ORCHID COMMITTEE —Present: H. J. Veitch, Esq. (in the chair); Messrs. J. O'Brien, T. W. Bond, C. Pilcher, E. Hill, J. Douglas, E. Handley, S. Courtauld, T. B. Haywood, and Dr. Masters.

Mr. P. McArthur sent a small collection tastefully arranged with

Ferns and Palms. Amongst these the beautiful Vanda Sanderiana, V. Sanderiana pallida, Oncidium Jonesianum, and Cypripedium Ashburtoniæ were conspicuous. W. Thompson, Esq., Walton Grange, Stone, had some spikes of Cattleya Alexandræ, for which a vote of thanks was accorded. A spray of Cattleya Brymeriana came from W. E. Brymer, Esq., Dorchester, and Messrs. W. L. Lewis & Co., Southgate, sent a few plants, including Cattleya Ashtoniana (C. Harrisonæ X C. gigas Sanderiana) Cattleya X Johnsoniana, and C. Loddigesi Pugetiana. Mr. J. O'Brien, Harrow-on-the-Hill, send blooms of Satyrium eriscarpum, S. membranaceum, and Brownlea cærulea (botanical certificate). Messrs. F. Sander & Co., St. Albans, had a small group of choice species. The most attractive of these were Cattleya aurea, Miltonia Moreliana, Cœlogyne oculata, Calanthe curculigoides, Cypripedium Schlimi, and the pretty Habenaria carnea, which is figured on page 283. E. Ashworth, Esq., Harefield Hall, Wilmslow, Cheshire, was accorded a cultural commendation for a fine plant of Dendrobium Phalænopsis Schröderianum Beatrice Ashworth var. The same exhibitor had a plant of D. P. Schröderianum Ashworth's var., a paler flower than the last named variety. A plant of Cypripedium Beatrice Ashworth (C. Leeanum X venustum) was also shown by Mr. Ashworth, likewise were blooms of other Orchids. W. Cobb, Esq., Dulcote, Tunbridge Wells (gardener, Mr. F. Howes) exhibited a plant of Catasetum Gnomus, for which a botanical certificate was awarded.

Messrs. B. S. Williams & Son showed a few choice Orchids, for one of which—Cattleya blesensis—they received an award of merit (see below). Messrs. Hugh Low & Co. had a varied and bright collection of Orchids backed by Lilium nepalense. The group included Cattleya maxima, Tricosentrum albo-sanguineum, Vanda cærulea, V. Kimballiana, and many good Cypripediums. Thos. Statter, Esq., Stand Hall, Manchester, sent Cattleya Alexandræ, C. Parthenia hybrid, and C. bicolor cærulea. Messrs. Charlesworth, Shuttleworth & Co. had a little group. cœrulea. Messrs. Charlesworth, Shuttleworth & Co., had a little group of much interest, the most noteworthy feature of which was a new Cypripedium named Charlesworthi, referred to under certificates below. They had Vanda cærulea very richly coloured, V. Sanderiana, Cattleya labiata autumnalis, and a number of Cypripediums. C. Ingram, Esq., Elstead House, Godalming (gardener, Mr. Bond), sent Lælia elegans

Turneri, Ingram's variety (see below).

CERTIFICATES AND AWARDS OF MERIT.

Aglaonema rotundum (J. Veitch & Sons).—A charming little foliage plant, with broadly lanceolate pointed leaves, deep rich green, blotched with light silvery green. It will make a good companion to A. costatum, exhibited some time ago (first-class certificate).

Alocasia Chantrieri (J. Laing & Son).—A variety with shield-shaped,

deep burnished green leaves, prominently ribbed (award of merit).

Begonia Duchess of York (J. Laing & Son).—A fine double flowered variety, blooms of medium size and rich cerise colour (award of merit). Cattleya blesensis (B. S. Williams & Son).—This is a cross between Cattleya Loddigesi and Lælia pumila. The flowers are of a uniform mauve shade, but the lip is richly coloured with purplish magenta

(award of merit).

Cypripedium Charlesworthi (Charlesworth, Shuttleworth & Co.). A very remarkable introduction from the East Indies. It is a distinct and beautiful species, very dwarf, with long, narrow leaves. The flower stem is only 3 to 4 inches long. The lip is short, green, heavily suffused with bronzy brown; and the dorsal sepal is very noteworthy. It is broad and rounded, and the colcuring is a beautiful soft rose, delicately veined. The staminode is pure white. A feature of the leafage are the rows of dots on the reverse side. The species is a great acquisition (first-class certificate).

Dahlia Octavia (C. Turner).—A fine yellow show faintly tipped

with red (award of merit).

Dahlia Mrs. Morgan (C. Turner),-A large and handsome show variety, blush deepening to pink (award of merit).

Dahlia Captain Boyton (C. Turner).—A very neat and pleasing Pompon, colour blacking purple, an acquisition (award of merit).

Dahlia Miranda (C. Turner).—A very distinct Pompon, yellow, heavily tipped with chocolate (award of merit).

Dahlia Beauty of Watford (Mr. Darby).—A pretty single variety of an cld gold colour, suffused with carmine, with a distinct brownish red ring in the centre (award of merit).

Dahlia Edith Turner (C. Turner).—A fine Cactus Dahlia with

flowers of a purplish scarlet colour (award of merit).

Dahlia Florence Woodland (T. S. Ware).—A beautiful Pompon, very

smooth and neat, yellow tipped with crimson (award of merit).

Dahlia Mrs. Peart (T. S. Ware).—A very promising white Cactus

which will meet a long-felt want (award of merit).

Dahlia Cherub (G. P. Pierre Harris, Esq.).—A variety of the Show type, with shapely flowers of a rich golden amber (award of merit).

Dahlia Grand Duke Alexis (Keynes, Williams & Co.).—A very large

white decorative variety, with folded florets (award of merit).

Dahlia Norma (C. Turner). — A grand new Show variety, large,

shapely, and of a beautiful golden amber colour (award of merit).

Dahlia Duchess of York (Keynes, Williams & Co.).—A fine show variety with neat blooms, terra cotta, heavily suffused and margined

magenta (award of merit). Dahlia Ceres (Keynes, Williams & Co.).—A pretty Pompon, flowers

neat and lemon colour (award of merit).

Dahlia Sovereign (Keynes, Williams & Co.).—A bright yellow

Pompon variety with neat blooms (award of mcrit).

Datura cornucopia (Pitcher & Manda).—A very handsome species; flowers white, with faint lilac suffusion, the reverse of the segments and tube having rich bluish mauve specklings and flakings. It is strongly scented (first-class certificate).

Heliopsis scabra major (B. Ladhams) .- A fine autumn Composite,

with flowers of a very rich deep yellow (award of merit).

**Lælia elegans Turneri, Ingram's variety (C. Ingram, Esq.).—A very large and richly coloured form, the lip being of great size, and coloured

with glowing purplish magenta (award of merit).

Nepenthes mixta (J. Veitch & Sons). — An interesting and highly coloured hybrid, raised by crossing N. Northiana (pollen parent) and N. Curtisi. The pitchers are long, somewhat narrow, greenish red, heavily blotched with deep brownish red (first-class certificate).

Veronica hybrida Purple Queen (J. Veitch & Sons).—A very free-

flowering, brightly coloured, and beautiful variety (award of merit).

THE LECTURE.

At the afternoon meeting, Mr. W. Iggulden, The Gardens, Marston House, Frome, gave a lecture on the "Causes of Failure in Eucharis Culture." There was a fair attendance and Mr. Iggulden dealt with his subject in a thoroughly practical manner, detailing the various causes of failure in the cultivation of this plant. A brief discussion followed, and a vote of thanks was accorded the lecturer.

EARL'S COURT SHOW.

SEPTEMBER 27TH, 28TH, AND 29TH.

A SPLENDID show of fruit and vegetables was opened at the Garden and Forestry Exhibition yesterday (Wednesday). The Apples were remarkably fine and well coloured, and the Pears were also good. The vegetables were not very numerous, but of excellent quality, the chief

feature being the fruit.

The principal class was for twenty-four dishes of dessert Apples, and seven exhibitors competed. The leading prize was awarded to Messrs. G. Bunyard & Co., Maidstone, who staged medium sized, even, and richly coloured fruits. Wealthy, Cobham, Gascoyne's Scedling, Cox's Pomona, King of the Pippins, and Worcester Pearmain were particularly good. Mr. H. Berwick, The Nurseries, Sidmouth, Devon, was second with fine fruit; the third prize going to Mr. John Scott, Marriott, Somerset. For a collection of culinary Apples comprising forty-eight dishes there were four competitors, and the first prize went to Messrs. G. Bunyard & Co., who had splendid fruits. The best of this collection were Cox's Pomona, Lane's Prince Albert, The Queen, Tyler's Kernel, Emperor Alexander, and Peasgood's Nonesuch. Mr. Woodward was second, and Mr. J. Scott followed closely. An extra prize was awarded the English Fruit and Rose Company for a good collection. Mr. Nicholson, gardener to J. W. Melles, Esq., Sewardstone Lodge, Chingford, was first for three dishes of culinary Apples; Mr. Cotteral, Oxon Hoath, Tonbridge, second; and The English Fruit and Rose Company, Hereford, third. Messrs. G. Bunyard & Co. were again first for twelve dishes of dessert Apples, the best being Worcester Pearmain, Wealthy, Washington, Swedish Reinette, Blenheim Orange, King of the Pippins, and Cox's Orange. Mr. G. Woodward, Barham Court Gardens, followed with a fine collection.

Mr. Woodward was awarded the first prize for twenty-four dishes of Apples in the amateurs' section. The fruit was fine and well coloured, especially Cox's Pomona, Mère de Ménage, and Worcester Pearmain. Mr. G. Goldsmith, gardener to Sir E. G. Loder, Bart., Leonardslee, Horsham, was second with a good collection, the third award going to Mr. G. Chambers, Beech Farm, Mereworth, Maidstone. Mr. S. H. Goodwin, Smartswell, Mereworth, secured first prize for twelve dishes of Apples, amongst which Cox's Pomona, Worcester Pearmain, King of the Pippins, and Peasgood's Nonesuch were particularly fine. Mr. J. Austin T. Killick, Weavering, Maidstone, was second, and Mr. Goldsmith third. Five competed in this class. Mr. W. Minifile, Bedlands, Sidmouth, was first for six dishes of Apples; Mr. Chambers being second; and Mr. James Hall, Croscombe, Wells, Somerset, third. Thirteen competed in the class for six dishes of dessert Apples, and the produce was good throughout. Mr. Chambers was the winner with fine fruits. The second prize went to Mr. R. Potter, gardener to Sir M. Collet, Bart., St. Clere, Kemsing, Sevenoaks; and the third to Mr. J. Hall. The English Fruit and Rose Company were third. For twelve dishes of Apples Mr. G. Woodward was first, Messrs. G. Bunyard & Co. second, and Mr. H. Penwick third. Berwick third. Messrs. G. Bunyard & Co. and T. Rivers & Son divided the prizes for twelve dishes of Apples and Pears grown in an orchard house.

Pears were also shown in splendid condition. In the class for twelve dishes there were nine competitors, and the leading award went to Mr. G. Goldsmith for a magnificent collection of fruit. Pitmaston Duchess, Marie Louise, Doyenné du Comice, and Beurré Clairgeau were very fine. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, was second, and Mr. G. Woodward third. Mr. W. Wills, Unsted Park, Godalming, was first for six dishes of Pears in one section, Mr. J. Dean, being second, and Mr. W. Slogrove, third. There were six competitors in the class for twenty-four dishes of Pears, and the prizes were keenly contested. Mr. G. Woodward was awarded the first prize, the second going to Mr. G. Goldsmith, and the third to Mr. W. Iggulden, Marston House Gardens, Somerset. M. A. Offer was first for twelve dishes of Pears, Mr. R. Smith, Presdale Gardens, Ware, being second, and Mr. H. Berwick third.

Vegetables, as already mentioned, were shown in good condition. For a collection of twelve kinds Mr. T. Wilkins, gardener to Lady Theodora Guest, Inwood House, Blandford, was first, showing splendid produce. Mr. G. J. Waite, Glenhurst, Esher, was a good second, the third prize going to Mr. J. Friend, Rooksnest Gardens, Godstone. There were seven competitors. Mr. E. Ryder, Orpington, was first with a collection of Tomatoes, the Frome Flower and Fruit Company second, and Mr. J. Welborn third. Messrs. J. Strong, E. Ryder, and J. Hall secured other prizes for Tomatoes. Messrs. T. Rivers and Son, G. Goldsmith, J. Friend, and J. Dean for Plums, and Messrs. G. Woodward, T. Rivers & Son, A. Offer, D. Fairweather, and H. Beanes for Peaches.

Miscellaneous exhibits were numerous. Mr. G. Reynolds had a collection of Melons (silver medal), and Mr. C. Terry, The Gardens, Tatton Park, Brentford, some Pine Apples (silver-gilt medal). Mr. C. Turner, Slough, exhibited a dish of very fine Mère de Ménage Apples, the heaviest veighing 221 erg. (highly commended). Mr. W. Manager, the heaviest weighing $22\frac{1}{2}$ ozs. (highly commended). Mr. W. Mancey, Upper Gatton, Redhill, had Pitmaston Duchess Pears, the heaviest of which weighed 2 lbs. (bronze medal). Mr. Goldsmith gained a bronze medal for Pomegranates. Messrs. T. Rivers & Son, Sawbridgeworth, gained a silver medal for a collection of Grapes, Apples and Pears, and was awarded the first prize for a splendid table of fruit, including trees of the Bijou Apples. Mr. J. Dibben, Tilgate House, Crawley, had a collection of Pears (bronze medal); Mr. T. M. Le Pelley, Rusper, Sussex, Grapes (bronze medal), and Mr. W. Minifie, Sidmouth, Peasgood's Nonesuch Apples (highly commended).

In the Exhibition buildings many miscellaneous exhibits were also staged. Mr. J. Strong had Tomatoes (bronze medal), and Mr. W. Salmon, West Norwood, a large collection of vegetables (silver medal). Mr. Henry Merryweather, The Nurseries, Southwell, Notts, had a fine collection of Bramley's Seedling Apples. Mr. A. Rawling secured a bronze medal for Dahlias, and Mr. Deverill, Banbury, a silvergilt medal for a magnificent collection of Onions. Messrs. H. Cannell and Sons had Begonia blooms, as also did Mr. A. W. Young, South Norwood. A bronze medal went to Mr. T. A. Hester, The Links, Plumstead Common, for a collection of Grapes Apples Pears and Nuts.

Plumstead Common, for a collection of Grapes, Apples, Pears, and Nuts.

Messrs. J. Veitch & Sons, Chelsea, gained a gold medal for a group of
Nononthes. Nepenthes. First-class certificates were awarded for N. Northiana, N. mixta, and N. Burkei excellens. The same firm sent a collection of cut hardy shrubs, and certificates were given for Cratægus pinnatifida major and Cornus stolonifera Spathi. Messrs. Veitch & Sons also gained certificates for Aglaonema rotundum, A. costatum, Cypripedium Niobe, C. Aphrodite, C. T. B. Haywood, C. Drysa, Catasetum Darwinianum, Pandanus pacificus, Rhododendrons Princess Beatrice, Aphrodite, and Ajax. Mr. A. Waterer, Knaphill Nursery, had Conifers (silver medal), and Messrs. J. Cheal & Sons a grand collection of Dahlias and Apples, but no award had been made when our reporter left. Messrs. W. Paul & Son, Waltham Cross, gained a silver medal for a collection of cut Roses and Apples. A first-class certificate was awarded for Duke of York Rose, a new China variety.

Mr. J. Watkins, Withington, Hereford, had a very fine collection of

Apples (silver medal), as also did Mr. H. Berwick, Messrs. J. Veitch and Sons, G. Bunyard & Co. (silver-gilt medal), but pressure on our space prevents further reference. Messrs. W. Innes & Co., Littleover, Derby, staged some well-grown Grapes (silver-gilt medal), and Messrs. G. Spooner & Sons, Hounslow, had Apples (silver medal). Messrs. J. Laing and Sons secured a bronze medal for Apples and Pears, as also did Mr. A. H. Rickwood, Fulwell Park, Twickenham. Messrs. H. Cannell and Sons secured a silver medal for a collection of vector blog and fruit and Sons secured a silver medal for a collection of vegetables and fruit, and Messrs. Keynes, Williams & Co., Salisbury, a similar honour for Dahlias. Certificates were awarded for Dahlias Apollo, Lady Penzance, Gloriosa, Sovereign, and Phœbe, shown by the Salisbury firm.

HARDY FRUIT GARDEN.

Wall Trees.—Branch Thinning.—At no period of the year can the evil of overcrowding branches be better noticed than at the present time while the foliage is still on the trees. Horizontally trained trees often have double the number of branches they should have. results are easily seen by the elongated spurs which are denuded of foliage at the base. This goes on continually when the sun cannot shine between the branches or spurs. Clusters of strong wood buds and weak fruit spurs struggle with each other. The lower branches usually suffer the most in this respect. The top tiers of branches and their extremities are often able to develop some fruitful spurs even when crowded, but it is seldom such can be found lower down the trees, which shows the great importance of light and air. Trees should be so managed that equal conditions can be secured to every part, then general fruitfulness will ensue. The main branches ought, as a rule, to be a foot asunder, except in the case of some varieties of Pears which, making slender wood and small foliage, will do with the branches 9 or 10 inches apart. Another point to be noticed is that branches with spurs standing out a considerable distance from the wall require more room between them than those on which the spurs are short.

Spur Pruning.—Along with removing some of the branches spurthinning is usually required, crowded elongated spurs being also conducive to unfruitfulness. Thinning spurs is usually done in the winter, but greater advantages follow if the operation is done while the

foliage remains. In the first place it can be effected more thoroughly while the leaves are present on the trees to guide the judgment in the selection of the best to retain; while the further advantage results with autumn as against winter pruning, that the buds left receive at once the active energies of the trees, helping them to become transformed more quickly into prominent fruitful buds.

Pruning Bush Apple Trees.—The present is also a suitable opportunity to thin out the wood of bush Apple trees. They will be fruitful at an earlier period if overcrowding is never allowed, and to effect this a little judicious thinning is necessary every season. Remove the badly placed shoots and those which intersect others, spoiling the appearance and contour of the trees. Severe shortening of the main shoots must not be adopted except where it is desired to originate more. Before young trees come into bearing long shoots are frequently made in one season. Such as these are backward in forming fruit buds if Therefore shorten the longest to half some slight check is not given. their length, others merely having their points removed, cutting to firm wood, and to a bud pointing in the right direction for extension. Next season, instead of the sap rushing straight to the leading point it will be diverted into the lower buds, causing fruit buds to form or side shoots to be produced, which in the summer shorten to four leaves, thus aiding the formation of fruit buds and preventing the interior being overcrowded with long spray.

Stopping Growths on Neglected Trees.—Scores of Apples and Pears grown on walls and in other restricted forms never receive any summer pruning, consequently the growth of foreright and side shoots on main branches is a continuation of the first growth, increasing in strength and length. Usually such shoots are shortened back at the present time, sometimes left for the winter pruning, with the idea that this is the correct method; but in neither case can the formation of fruit buds be relied on to take place, owing to the excessive appropriation of sap by these rampant growths. It is, however, better to shorten them now to four or five leaves than to permit them to remain. Their removal will, at least, admit light and air to any weak fruit buds which may be clustering near the base, improving and strengthening them whereby they can take advantage of more rational treatment to be followed another season. The strongest growers will be benefited by root-pruning.

FRUIT FORCING.

Pines.—Suckers.—These, started early in September, or recently, should be raised near the glass as soon as they have made good roots, for it is essential that those intended to be wintered in small pots be brought forward very gradually, so as to secure a sturdy base. This must not be sought by withdrawing the plants from bottom heat, as that would render the growth stunted. When the suckers have well filled their pots with roots the strongest plants may be transferred to the pots in which they are to fruit.

Growing Stock.—Young plants will need free ventilation on all favourable occasions to maintain them in a healthy sturdy condition, keeping the bottom heat about the roots at 80°, and maintaining a temperature from fire heat of 60° to 65° at night, with 5° to 10° rise by Water the plants when they require it, employing weak and tepid liquid manure, and avoid the use of the syringe too frequently; merely sprinkling the paths and pit sides morning and evening will suffice in all but very bright weather.

Fruiting Plants.—Afford these a night temperature of 70°, 80° to 90° during the day, closing at 85°. The watering should only be moderate at the roots, as an excess is liable to cause the fruit to become black at the centre. Moderate moisture also must only be accorded, for when kept very close and moist the crowns are apt to become unduly large, and the glass should be kept clean, with the plants as near to it as

practicable without the crowns touching.

Cherries.—With plenty of air and not too much heat up to the stoning period Cherries may be had in April or May. They can be grown either planted out or in pots. Inexpensive houses with boarded sides and a glass roof answer as well as more elaborate structures. It is nccessary that the house be well ventilated both at top and bottom, and efficiently heated. Wooden ventilators should be provided at the front or sides just above the floor line, and at the top to open the whole length of the house. In addition to this drain tiles may be laid in the soil in channels about 6 feet asunder crosswise of the house, with the ends taken outside and above the surface by elbows, and the drains should have sockets at 3 feet within the house, and then 6 feet apart, with pipes coming above the surface. With caps for the outside openings and similar ones for the inside air cap be admitted by these drains in the similar ones for the inside air can be admitted by these drains in the severest weather. The trees may be planted out in front of a lean-to and be trained to a trellis fixed 12 inches from the glass, the treeshaving stems reaching to within a few inches of the trellis. The roof lights for planted out trees should be moveable, and it is better to allow the trees to occupy the whole of the roof than have them partly so, and others against the back wall.

A lean-to structure is best for early forcing, and two rows of 4-inch pipes in front will suffice for a house of 10 to 12 feet width. Span-roofed nouses will accommodate trees on both sides of them, and for widths of 18 to 24 feet will require two rows of 3 and 4-inch hot-water pipes respectively on each side. The border should be wholly inside and not made all at once. A 4 to 6 feet width of border according to the size of the trees is sufficient to commence with. It should be drained 9 inches to a foot deep, having a drain to carry off superfluous water, placing the roughest at the bottom and least coarse on top, covering with a 3-inch thickness of old mortar rubbish. From 21 to 24 inches depth of soil is ample. Good turfy loam four parts, lime rubbish from an old

building one part, and road scrapings one part, chopping the turfy loam moderately small, and mixing well together forms a suitable compost. If the top 3 or 4 inches of a pasture can be had where the soil is a rather strong loam interspersed with calcareous gravel and flints, it could not possibly be better for this or any stone fruit, and needs no admixture. Trees, that have been trained two or three years to walls are best, as they come into bearing at once, and will move safely provided they have been recently lifted. The borders being firm plant at once, or as soon as the leaves have mainly fallen, and give a good watering. Mulch with a couple of inches thickness of short stable litter, and take off the roof lights, not replacing them until the new year, when the trees may be started. Early Rivers Black Tartarian, and Governor Wood are the be started. Early Rivers, Black Tartarian, and Governor Wood are the best for trellises.

best for trellises.

I. Cherries in Pots.—These are very accommodating, and may be grown in any light, airy, well heated houses. The trees may be procured at once. They ought to be in pots, if not they will require a year to become thoroughly established. Repot at once if necessary, disentangling the roots at the sides of the ball, removing the drainage, and shortening any thick or straggling roots. Provide good drainage and make the soil firm, adding a fourth of well decayed manure to the compost for potting. Trees that are in as large pots as desired need only have the drainage rectified and be surface dressed, or the old drainage may be cleared away, a few inches from the base of the ball removed, the roots shortened back, removing all the loose surface soil and supplythe roots shortened back, removing all the loose surface soil and supplying fresh material, made firm under, around, and over the ball. The trees should be placed on a hard bottom impervious to worms, and surrounded with ashes to the rim, covering the pots with litter upon the approach of frost. Afford a good watering after potting or having the roots interfered with. Guigne Annonay, Early Rivers, Empress Eugénie, Early Red Guigne, Early Jaboulay, Early Red Bigarreau, May Duke, Black Tartarian, Governor Wood, and Elton are excellent varieties, and afford fruitin succession. The trees may be in pyramidal form, but low standards, so that the heads will be well up to the glass, are most desirable.

Cucumbers.—The plants for winter fruiting should be planted as soon as they are ready if not already done. A good bottom heat is essential to success, whether it be obtained by the aid of fermenting materials or hot-water pipes, but the latter is the most desirable means, and if the former are used there should be hot-water pipes in the bed to maintain the heat when that of the fermenting material declines. The soil may consist of light turfy loam with a third of fibrous peat, a sixth of old mortar rubbish, and a tenth of charcoal, the whole well incorporated. Reliance should be placed on liquid manure and surface dressings for imparting vigour later in preference to employ-

ing manure in the compost.

Autumn Fruiters.—A healthy and vigorous growth must be maintained, and do not overcrop the plants. Afford weak tepid liquid manure once or twice a week as may be necessary. Add a little fresh warmed soil about once a fortnight to the hillocks or ridges. Maintain a night temperature of 65°, 70° to 75° by day artificially, and 80° to 90° from sun heat. Avoid a close atmosphere by careful and moderate ventilation, but cold drying currents must be prevented, for they are very injurious. Be sparing in the use of water, especially on the foliage, keeping a genial condition of the atmosphere by damping the surface in the morning and afternoon, but gradually reduce the atmospheric moisture as the days shorten and the natural heat declines. If aphides attack the plants fumigate on two or three consecutive

evenings; for mildew dust with flowers of sulphur.

Strawberries in Pots. — A selection should now be made of the plants for early forcing, taking those which are in the forwardest condition as regards completing their growth and plumping the crowns. La Grosse Sucrée and Vicomtesse Hericart de Thury are, all points considered, the best. They may remain outdoors until the approach of frost, and should then be placed well up to the glass in frames, only affording protection from heavy rains and frost, otherwise exposing fully or ventilating freely. The plants must not lack water, yet needless applications cause the soil to become sodden and sour. Any plants that appear in the latter condition should have the drainage examined. Expel worms from the pots with lime water, and rectify the drainage where defective. Where the crowns are numerous, the small ones should be removed with a wedge-like piece of hard wood without injuring the leaves or central crown. This will concentrate all the vigour of the plants on the chief crown, and though there will be fewer trusses of bloom there is no need to fear a deficiency of crop, but it must not be carried too far, and in the case of split crowns, that is, the central one divided into two or three, these must be left, removing the small side ones only. The plants must have plenty of space for the full exposure of the foliage, which is essential to a sturdy growth and plump well-developed crowns. Remove all runners and weeds as they appear.

APIARIAN NOTES.

PRACTICAL HINTS FOR BEGINNERS.

THE reader must bear in mind as he peruses these notes, that the writer has had a wide experience in bees and bee-keeping, sufficient to enable him to answer almost any query concerning bees, and to affirm positively that the Lanarkshire divisional hive is the only one adapted for moving bees with safety from place to place, as from the home apiary to the orchard, thence to the Clover, and eventually to the Heather. It is the only hive in which we can say in the autumn, when all is arranged, the bees are safe till May or longer. It will therefore be the only hive

alluded to in these notes.

But bee-keepers are their own masters, and beginners are at liberty to make experiments, and trials of different things and on different lines from what I teach; at the same time it must be understood that the many mishaps in wintering and moving bees in summer, together with unnecessary expenses connected with large and double cased hives, warrant me giving the foregoing warning. Read the book of Nature, then the singular and often mysterious movements occurring in the hive will become plain and easily understood. Learn the "hows and the whys," and beekeeping will become an easy, profitable, and interesting pursuit.

TENANTS OF THE HIVE.

These are the queen, workers, and drones during the summer, and not unfrequently fertile workers, drone-producing queens, and hermaphrodites. As every text book gives illustrations of the former, it is needless to enlarge on them here further than is necessary to make plain to the novice their mission in the hive.

"It is difficult to catch the queen," or "I have never seen one" are expressions not unseldom used by beginners. Experienced beekeepers have not unfrequently from the smallness of some queens great difficulty in spotting or catching them, but it is often undesirable to waste time hunting for them, as there are ways of disposing of them, as will be hereafter explained. Meanwhile the best illustration of a queen beginners can get is, when queens are heard piping in the hive to open it and secure a ripe cell. It is known by its dark brown appearance over the seal and its edge, as the seal sometimes falls back after the queen has left and is again sealed by the bees. Make sure the cell contains a queen. Vibrations by its movements are distinctly felt, and it can be seen in the cell when held between the eye and the light. Now place the cell with a few workers on a piece of comb under a glass, where you can watch the exit and other movements, and have a full view of a live queen bee and all her movements better than pen or pencil can describe.—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

LANARKSHIRE DIVISIONAL HIVE.

I OBTAINED two hives and like them, only I am somewhat in difficulties about the management. You kindly told me how to pack them for winter, but I want to know about sufficiency of room. I drove and put a stock in three weeks since, placing with it other two stocks; they were not very strong. I put them on worked out combs, so there is no building for them, and I have fed them slowly with syrup; but I fancy the one box will hardly be large enough. Perhaps you might kindly tell me in the Journal of Horticulture. The "B. B. J." says we should replace old queens with young ones, but I cannot find the queens. I suppose it is a difficulty for novices, so I must leave them alone and trust they will be all right.—S. M. H.

[In reply to "S. M. H.," it depends greatly upon whether the hive is intended as a swarmer or non-swarmer, and on the locality producing flowers that yield the principal supply of honey whether the bees should occupy two or three divisions. One at any time is too small. If the bees swarm several weeks before the honeyyielding flowers are in bloom, then two divisions are suitable; but if the flora of the district comes before the bees are ready for swarming, prepare the hive now in three divisions full combed, having a youthful queen. If the hive is well supplied with stores it will attain a good strength, and the bees will be able to gather much honey in the early part of the year before attempting to

It is not very long since the "B. B. J." taught that queens were at their best when three years old, and perhaps took the hint about youthful queens from the pages of the Journal of Horticulture. As you have joined two old stocks to the original

probably one of their queens is saved: usually old or swarmed

stocks have young queens.

There have been many mishaps in feeding bees with syrup made after a recipe in the "B. B. J.;" it is by far too thick. The proportions of the best cane sugar and water should be equal in weight. For various reasons I neither spend time nor money on the paper mentioned, so cannot help inquirers outside of the columns of the Journal of Horticulture.—A. L. B. K.]

CARNIOLAN BEES.

An error has occurred on page 278. The matter should read, I am perhaps prejudiced in favour (not against) of the pure Carniolans free from the yellow bands, but cannot help admiring their good qualities in honey gathering, purity of comb, and mild temper, or, in other words, after disproving by actual trial and experiment nearly all that has been written elsewhere against Punics, I prefer Carniolans.—A. L. B. K.

THE INGENUITY OF BEES.

CAN bees learn to tell the time of day as well as a clock? A correspondent of "Science Siftings" lately noticed that a large number of bees were frequenting the flowers on his lawn, and every day when he came home to lunch he put a lump of sugar on a brick in the garden for them. They soon learned the time when they might expect the sugar, and now, when he goes out at noon, he finds about 100 bees sitting around waiting for their lunch.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Calla æthiopica Seedlings (T. W. W.).—Calla æthiopica is popularly known as the Arum Lily, but seedlings vary somewhat in foliage as well as in form of spathes, and you can only ascertain the character of your plants by flowering them.

Cobæa scandens alba (H. R. Richards).— We have not seen flowers so nearly approaching pure white as those you have sent, nor does Mr. G. Nicholson, of Kew, remember seeing any quite so white as these specimens of yours which he has examined.

Insecticides (T. A.).—We have not a doubt that what you say is correct, but your letter is written in a form that brings it distinctly within the category of advertisements, and could only appear by an arrangement with the publisher on the usual business lines.

Culture of Erythrinas (Young Gardener) .- The following hints, written by a most successful cultivator of these plants, exactly answer your question:—"Erythrinas are very handsome easily grown plants, and we strongly recommend them to those whose accommodation for growing plants is limited, because they may be kept all the winter in any kind of place where frost does not penetrate; after they are started in spring may be wholly grown outside, and only removed to the greenhouse as they come into flower. They are remarkably profuse flowering plants, and their wants are few. A mixture of loam and leaf soil, with a good dash of sand and a few pieces of charcoal, suits them admirably. An annual potting just as they start will be sufficient for ordinarily large plants, and an annual pruning—which consists in cutting off all the summer's growth down to the rim of the pot—coupled with such treatment as we have hinted at, will insure success. We advise a little heat for starting them in, though, because they start more regularly than if left outside. If put in a warm temperature we advise careful hardening-off and placing outside early in June; their removal inside when the first flowers show themselves. After they are cut down they should be kept rather dry and away from frost. E. crista-galli is the best known, and a fine plant it is. It is hardy in the warmer districts of England and Ireland, but must rank as an easily grown greenhouse plant in the less favoured districts of these islands.

Thin Runner Beans (T. W.).—The variety sent is of a different type to the ordinary Scarlet Runner, the pods being, as a rule, less fleshy, but more delicate in flavour. Those you send are too old for cooking, and the older they are the more "skinny" they become. The season has been very unfavourable for Runner Beans, and the produce has, in consequence, not been so good as usual, though dearer in the markets, and we suspect that ripe seed will be much above the average price in bulk. We think you should send samples of the Bean to the introducers of the variety and the vendors of seed, and hear what they have to say on the subject.

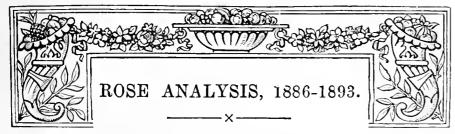

Destroying Ants (D.).—As you have fruit about and the ants visit it, it would not be safe to use poison. There is no better plan than to procure some partially picked meat bones and place them near their haunts. In a short time the ants will cover the bones, which can be placed in a bucket of boiling water. Another set of bones should then be laid, and more ants will visit them, often covering them in their eagerness to appropriate the flesh. In the meantime the bones first used should be placed in a sieve to dry, and then may be used again as baits. This simple plan will soon clear off thousands of ants provided it is persistently practised.

Euphorbia splendens (B. P. S.). — The plant of which you sent a specimen is Euphorbia splendens. It is of easy culture, requiring a stove temperature and a soil of fibrous loam and sand, with a small proportion of lime rubbish. The pots should be well drained, as any stagnant moisture is especially injurious to the plants, as their stems are very succulent. When the plants are growing freely water may be liberally supplied, liquid manure being also beneficial occasionally. Although succeeding well in pots this Euphorbia is more useful if planted out in a border against a wall in the stove, where flowers will be freely produced, during a considerable portion of the year.

Sambucus nigra aurea (Elder).—You are right, this is more golden than the old Gold-variegated Elder (Sambucus nigra variegata), being quite yellow in the matured growths, and which it retains to the close of the season. It is of very free growth, and though Elder may be common it is fit to take rank with the choicest of variegated shrubs, not the least of the merits of Elders being that of their thriving in the vitiated atmosphere of manufacturing localities, and they do well near the sea; in fact, screens of Elder are the best as screens or shelter from sea breezes for choicer plants—choicer simply because less free-growing and less common. The Silver-variegated Elder (Sambucus nigra argentea) is not nearly so effective as this; still it is a desirable shrub or small tree, and especially as it will grow anywhere.

The Lady Apple (W. M.).—The Apple to which you refer is the Api of pomologists, and the following description and history from the "Fruit Manual" may be of interest to you:—"A beautiful little dessert Apple; in use from October to April. It should be eaten with the skin on, as it is there that the perfume is contained. The skin is very sensitive of shade, and any device may be formed upon it by causing pieces of paper, in the form of the design required, to adhere on the side exposed to the sun before it has attained its deep red colour. The tree is of a pyramidal habit of growth, healthy, and an abundant bearer. It succeeds well in almost any situation provided the soil is rich, loamy, and not too light or dry, and may be grown with equal success either on the Doucin or Crab stock. When worked on the French Paradise it is well adapted for pot culture. The fruit is firmly attached to the spurs, and forcibly resists the effects of high winds. According to Merlet the Api was first discovered as a wilding in the Forest of Api, in Brittany. It has been asserted that this Apple was brought from Peloponessus to Rome by Appius Claudius. Whether this be true or not there can be no doubt it is of great antiquity, as all the oldest authors regard it as the production of an age prior to their own. Although mentioned by most of the early continental writers, the Api does not appear to have been known in this country till towards the end of the seventeenth century. It is first mentioned by Worlidge, who calls it 'Pomme Appease, a curious Apple, lately propagated; the fruit is small and pleasant, which the Madams of France carry in their pockets, by reason they yield no unpleasant scent.' Lister, in his 'Journey to Paris, 1698,' speaking of this as being one of the Apples served up in the dessert, says, 'Also the Pome d'Apis, which is served here more for show than for use; being a small flat Apple, very beautiful, and very red on one side and pale or white on the other, and may serve the ladies at their toilets as a pattern to paint by.' De Quintinye calls it 'Une Pomme des damoiselles et de bonne compagnie.' Under the name of Lady Apple large quantities of the Api are annually imported to this country from the United States, where it is grown to a great extent, and produces a considerable return to the growers, as it always commands the highest price of any other fancy Apple in the market. In the winter months they may be seen encircled with various coloured tissue papers adorning the windows of the fruiterers in Covent Garden Market.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only

Palace on the 1st of July last, as regards both the number and quality of the flowers staged fell far short of what we expect to see at "the National." In fact, we have to go back nine years in order to find so small a display of Rose blooms. This year's display has been likened to that of 1879, when instead of the season being a singularly dry, hot, and early one it was nearly as abnormally cold, wet, and backward. On that occasion, however, instead of 4660 Hybrid Perpetual and Tea and Noisette Roses being staged, as was the case in 1893, there were then only 1880, or less than half the number. It was also in other respects much inferior, so that exhibitors as well as visitors will see what they have to expect should our fickle climate treat us to a Rose season as unprecedentedly late as that of 1893 was forward.

It is the proud boast of the National Rose Society that on whatever date their metropolitan exhibition be held, or whatever the character of the season, they never fail to attract to their leading show the cream of all the Roses throughout the country which happen at that particular period to be in flower. This year our English rosarians have had to contend against conditions of weather, at all events as regards heat, dryness, and continued sunshine, without precedent during the seventeen years that the Society has been established; and taking all three adverse conditions together, as far as I can gather unequalled during the present century. So that regarded from another and I think a more reasonable standpoint their Crystal Palace Show of 1893 must be looked upon as having been a highly creditable one considering the very exceptional character of the spring and summer. The only wonder to me is that anyone could expect to see anything like an average exhibition after such a long and trying spell of drought and heat and in such a remarkably forward year. In fact, the calendar had become so utterly deranged that throughout the Rose season instead of May we had to read June; instead of June, July; and instead of July, August.

Notwithstanding all these drawbacks there were to be seen scattered here and there throughout the Show a fair sprinkling of choice blooms — blooms sufficiently fine to satisfy even the most exacting of critics, and which any ardent Rose lover would travel many miles to feast his eyes upon. And this is an advantage "the National" possesses over all other Rose shows in that, drawing its supply of Roses from a much more extended area, there are sure to be certain favoured localities from which choice specimens may always be expected. In fact, there was even in the poor and scanty display of 1879 one grand bloom of Niphetos which, if my memory serves me rightly, I have never since seen equalled. At all events, such an impression did this flower leave on my mind at the time that I thought it worth while making a special pilgrimage to Hereford in order to worship the plant from which it had been gathered.

The total number of Rose blooms tabulated for the purpose of this analysis has been about 15,000, the number of names taken down from the prize stands at each of the eight exhibitions being as follows:—

1886 1887 1888 1889 1890 1891 1892 1893 Hybrid Perpetuals... 1038 1121 1067 1130 1247 1176 1396 1184 Teas and Noisettes... 509 642 631 662 554 635 854 778 1547 1772 2101 1954 2027 1846 1675 1702 The effect of the abnormal character of the seasons upon our analysis will be at once seen on glancing down the tables and noticing the number of times the different varieties were set up in the winning boxes this year as compared with their average performances at the eight exhibitions. I may here explain that in order to bring these averages (which govern the relative positions of the Roses in the tables) up to date and make them of more practical value, they have this year been recalculated on similar lines to those followed in my last Dahlia analysis.

The Hybrid Perpetuals, which at none of the previous seven shows had been as numerously staged, were the following:—Alfred Colomb, Dupuy Jamain, Horace Vernet, Duke of Wellington, Camille Bernardin, Fisher Holmes, Earl of Dufferin, Duchess of Bedford, Reynolds Hole, and J. S. Mill. On the other hand, Madame G. Luizet, La France, A. K. Williams, F. Michelon, Captain Christy, Lady Mary Fitzwilliam, Marie Finger, Marquise de Castellane, Duchesse de Vallombrosa, and Star of Waltham were never before so scantily shown. It will thus be seen that for once the late-flowering varieties were specially favoured, while those which bloom early in the season were as a rule but indifferently represented.

Mrs. John Laing, an English variety raised by the late Mr. Henry Bennett and first sent out by him in 1887, now heads the list of Hybrid Perpetuals. It is a grand all-round Rose, and well deserves the position it has for the first time gained. Both last year and this it was staged more frequently than any other H.P. in the Show. The fact is, that although distributed six years ago it is only during the last two seasons that plants of it have been grown in sufficiently large numbers by exhibitors generally to enable it to take the place in the table to which it was entitled. Alfred Colomb, a rather late-flowering sort, was almost as frequently staged this year as the premier flower. Camille Bernardin, Horace Vernet, Duke of Wellington, and Fisher Holmes were also to be found in an unusually large number of winning stands.

Last year there were only four Roses on the list of Hybrid Perpetuals which were less than six years old. This year, however, we have six-Gustave Piganeau, Sir R. Hill, Jeannie Dickson, Marchioness of Dufferin, Duke of Fife, and Margaret Dickson. Only one of these new sorts comes to us from France, the remaining five being all of British origin. Sir Rowland Hill (No. 36), a plum-coloured sport from Charles Lefebvre, and the sole representative of the year 1888, was staged twice as often as at any of the three previous exhibitions. Next in order of age comes Gustave Piganeau, an 1889 variety, which I ventured to predict last year would at no distant date occupy one of the leading places in the analysis. I, however, never anticipated that it would rise in the list as rapidly as it has done—at one bound leaping from No. 46 to No. 8. It is by no means a strong grower, but like Mrs. J. Laing is free flowering and dependable. I am rather surprised to find that Jeannie Dickson still remains very much in the same position as last year, but as likely as not this may be entirely due to the peculiar character of the season. It was sent out in 1890, and will be found at No. 47. Both of the 1891 varieties, Marchioness of Dufferin (No. 53) and Margaret Dickson (No. 59), find places in the table for the first time. The past season seems to have suited the former admirably, but cooler conditions of climate are evidently required to bring the latter to perfection. The remaining new Rose, Duke of Fife (No. 59), a bright crimson sport from Etienne Levet, only came out last year, but should it prove constant is sure to become a general favourite when better known.

That beautiful Tea Rose Catherine Mermet still heads the list of Teas and Noisettes. There is no other variety which can show anything like as steady a record or which appears less at the mercy of the seasons. Indeed, at the last seven exhibitions the number of blooms tabulated has varied only from thirty-nine to forty-six.

No. 2349.—Vol. LXXXIX., OLD SERIES.

Comtesse de Nadaillac appeared this year in no fewer than fifty-one different prize stands, or in a greater number than any Rose whatever in the exhibition, and is the only Tea which distinguished itself by being staged more frequently than at any of the seven previous exhibitions. There were, however, eight varieties which

at none of those shows had been as poorly represented as this year viz., Niphetos, Caroline Kuster, Madame de Watteville, Jean Ducher, Madame Bravy, Princess of Wales, Souvenir de Paul Neyron, and Madame Willermoz.

The newer sorts in this section, for some reason or other, appear

as a rule to take a longer time than the new H.P.'s in coming into general cultivation. For instance, taking the two varieties sent out in 1887, Madame Hoste (No. 15), and Ethel Brownlow (No. 20), it is only at this year's show that either of these fine Teas has reached double figures. Ernest Metz (No. 7), first distributed in 1888, is, however, an honourable exception to this rule, having been staged twelve times at the 1892 exhibition, and as many as thirty times in 1893. In fact, there were this year only seven other varieties more frequently shown in the prize stands. The year 1889 finds two representatives; of these Souvenir de S. A. Prince, a pure white sport from Souvenir d'un Ami, takes for the first time a good place in the analysis, standing now at No. 10, between Maréchal Niel and Madame de Watteville. Cleopatra of the same year does not seem to have been at all favoured by the past season, having fallen since last year from No. 17 to No. 24. So fine and certain a flower is, however, pretty sure to makes its mark sooner or later, notwithstanding the slender habit of growth of the plant.

Although such a bad year for Roses generally, the summer of 1893 seems to have suited admirably both of the varieties which, in my opinion, are the choicest gems of the two sections into which this analysis is divided. I refer to Horace Vernet, the finest of the dark H.P.'s, and to Comtesse de Nadaillac, the most exquisitely tinted of all the Teas. This is certainly remarkable, as neither Rose can be regarded as by any means a

strong grower.

The sad loss the Rose world has recently sustained in the death of that champion raiser of Tea Roses, Monsieur J. B. Guillot, causes us to look down the two lists and note the many priceless treasures for which we are indebted to the Guillot family. Among the Hybrid Perpetuals we find La France, Horace Vernet, Comtesse d'Oxford, Sénateur Vaisse, and Monsieur Noman; and in the table of Tea Roses Catherine Mermet, the premier flower; Comtesse de Nadaillac, only second on the list, and when at its best second to none; Ernest Metz, the rapidly rising favourite; Madame de Watteville, the lovely "butterfly Tea;" Madame Cusin, the most distinct and charming of the red Teas; Madame Hoste, the most reliable of the yellows; Hon. Edith Gifford, the best all-round Tea; Madame Bravy, the oldest of the Guillot series; Etoile de

Lyon, and Madame H. Jamain. Surely a matchless record this! At the end of this paper will also be found the names of six beautiful "garden Roses," sent out by Guillot during the last ten years. Before closing the analysis it is once more my pleasing duty to express my best thanks to those kind friends who assisted me in taking down the names of the Roses in the winning stands.

To those who have but little experience in Rose culture the following se'ect lists may, I trust, prove of service, as I have endeavoured to include in them only choice varieties of good

growth and constitution.

HYBRID PERPETUALS.—Light coloured varieties.—Mrs. John Laing, Madame Gabriel Luizet, Merveille de Lyon, Baroness Rothschild, Marie Finger, and Jeannie Dickson. Medium Reds.—Ulrich Brunner, François Michelon, Marquise de Castellane, Dupuy Jamain, Camille Bernardin, Comtesse d'Oxford, Heinrich Schultheis. Reds.—A. K. Williams, Marie Baumann, Alfred Colomb, Ferdinand de Lesseps, E. Y. Teas, Duke of Edinburgh, Dr. Andry, Fisher Holmes, Victor Hugo, Sénateur Vaisse, and Earl of Pembroke. Dark varieties.— Charles Lefebvre, Louis Van Houtte, Prince Arthur, Duke of Wellington, Earl of Dufferin, Prince Camille de Rohan, Sir Rowland Hill, and Duke of Connaught.

HYBRID TEAS.—La France, Captain Christy, Grace Darling,

Augustine Guinoisseau, and Viscountess Folkestone.

Teas and Noisettes.—Innocente Pirola, Souvenir d'un Ami, Marie Van Houtte, Ernest Metz, Souvenir de S. A. Prince, Caroline Kuster (N.), Francisca Krüger, Anna Ollivier, Madame Hoste, Hon. Edith Gifford, Madame Lambard, Rubens, and Jules Finger.

Bourbon.—Souvenir de la Malmaison and Mrs. Paul.

Garden Roses.—The following are a few non-exhibition Roses of comparatively recent introduction which I have grown and can recommend. Hybrid Perpetual: Gloire de Margottin*. Hybrid Teas: Bardou Job, Gloire Lyonnaise*, Gustave Regis. China: Laurette Messimy*. Teas and Noisettes: Dr. Grill, L'Ideal (N.), Luciole*, Princesse de Sagan*. Polyantha: Gloire des Polyanthes*. Of the above ten varieties, those marked by an asterisk, six in number, were raised by Guillot.—E. M., Berkhamsted.

31	5.0	1	Madame Willermoz	1845	Lacharme	Creamy white

HERBACEOUS PLANTS.

I AM afraid that all growers of these will find at the end of the season that they will have a heavy death roll to enumerate, especially in those parts of the country where water has been scarce. They may not at present have altogether perished, but I imagine that many of them will be in so weakly a condition that they will hardly be able to contend with the attacks of frost should we have anything like a severe winter. In the observations which I now venture to offer I do not lay claim to any special advantage or success, and the plants about which I have to speak are not of those difficult and trying kinds whose habits and wants seem to perplex us, and yet afford to some persons the opportunities they seek for in combating difficulties and triumphing over many obstacles. It is no doubt a delightful thing to be able to point to some plant which has baffled cultivators, and with laudable pride to be able to say, "I have mastered it."

Bearing in mind the controversy that arose some time ago with regard to the definition of these plants I venture to include Lilies amongst them; they are ever to me and to many others one of the most interesting classes of plants that we grow, and perhaps the season through which we have passed has been one of the most trying that we have experienced of late years. To some of them such as L. superbum (the Swamp Lily as it is called) the weather has been especially trying. My plants have grown about 18 inches or 2 feet, and have not flowered at all; while others such as Hansoni and Humbolti have thrown up stems and then withered away without the slightest attempt to flower; others it is true, such as Browni

and dalmaticum, have done fairly well.

While mentioning this beautiful class of plants I may draw attention to some blooms which were sent me the other day by Messrs. Wallace & Co., amongst them was a bloom of that very beautiful novelty Lilium Henryi, which has been frequently exhibited lately and attracted considerable attention, but will it retain that position? It is said that it may be fitly described as an orange speciosum, but it bears so close a resemblance to some of the forms of the Turk's Cap that it looks more as if it were related to them; however, as its price will leave it for some time in only a few hands I must be contented to admire it at a distance, and should I say anything disparagingly it might be set down to the old adage "that Grapes are sour." At the same time they sent me some blooms of fine forms of Lilium speciosum, all of which with one exception I have grown, this was Album novum, a fine form of the white speciosum. It, however, bears a very strong resemblance to one which I received from Holland under the name of Vestal; another was Melpomene which I have grown for some years but which now seems to be becoming more plentiful. It was, I believe, raised by the late Mr. Hovey of Boston, U.S., and is certainly the richest in colour of all varieties of speciosum.

It is remarkable how little has been done in the way of hybridising these Lilies. Some years ago a very fine variety called Parkmanni was figured in the "Florist and Pomologist." It was said to have been raised in America, and the stock came into the possession of Mr. Anthony Waterer; but like one of its parents, auratum, it seems to be a difficult bulb to grow, and although many years have passed he appears to have been unable to get up a stock of it. His want of success in hybridising seems to be the more strange if, as is stated by some botanists, auratum itself is a natural hybrid between speciosum and longiflorum, and is catalogued by some bulb growers as speciosum imperialis. The others were cruentum and macranthum, the former a rich colour variety approaching Melpomene. Amongst other Lilies, Browni succeeded well with me, but have not been able to do anything with Krameri either in pots or the open ground. I have tried it in various ways, even in pure cow manure and sand as recommended by Max Leitchlin, but in all

cases I have failed.

VERBASCUM OLYMPICUM.—I draw attention to this grand herbaceous plant for two reasons. I do not think that it is grown as much as it ought to be, for it is a noble-looking plant, its large leaves 3 feet long, and its grand branching flowering stem from 8 to 10 feet high, with its bright yellow flowers produced in great profusion, make it a conspicuous object and peculiarly adapting it for large places; besides when the centre stem is cut down from eighteen to twenty smaller branches are filled with flowers though not quite so large as those produced on the main stalk. The other reason I have for mentioning it is that although considered as a biennial it is not always so. Öut of the three or four plants that I had there is one which flowered last year, and has thrown up a large shoot from the root with fine vigorous leaves, which will form a good flowering plant for next year.

SCABIOSA OCHROLEUCA.—A plant which I have received under this name is said not to be a Scabious at all, but a Cephalaria; however that may be it is very Scabious like in appearance, and is an effective plant; the flowering stems are 3 feet high, and the colour of the flowers a soft shade of primrose. Of so well known a flower as Scabiosa caucasica it is hardly necessary to say a favourable word, but its long flowering habit, continuing as it does in bloom for three months, and its pleasing shade of colour, ought to secure it a place everywhere.

COLCHICUM SPECIOSUM. — Among the various varieties of Colchicum (or as they are called in Kent Naked Boys), there is none that I have seen equals this for the size and substance of its petals. I received my bulb a couple of years ago from my friend, Mr. Ewbank, and it has now established itself, and is doing well.

ENOTHERA MARGINATA.—This, to my mind, the most beautiful of the dwarf varieties of Evening Primroses, has made itself most thoroughly at home with me, though I have heard of persons who have found it difficult to manage. The worst point about it is its rambling habit. I planted it on one side of the walk, and under which said walk it has found its way and has come up on the other side, having left its original location, and now forms a compact mass about 4 feet square. Enothera taraxacifolia is I believe

very similar to this, but keeps more at home.

EREMURI.—I mention these, not because I have had any success with them, for my attempts have proved failures. Twice I tried E. robustus, and I have altogether lost it; and once I received a root from Holland under the name of Olgæ, which flourished, but turned out to be a worthless Asphodel. I grieved for these failures, especially when last year 1 saw a grand spike exhibited by my friend Mr. Page Roberts at Chester. There are four species under cultivation, but they are somewhat difficult to procure, for though they seed freely it requires five or six years to bring them to the condition of flowering plants. Eremurus robustus is a magnificent stately plant, in colour soft rosy pink with yellow centre, a spike being about 2 feet in length. I have heard the foliage described as handsome, but I cannot say as far as my experience goes that I consider it so. The leaves are long but very brittle, and were constantly broken by high winds. A grand spike of this was exhibited by Mr. Pritchard of Christchurch, Hants, at the Temple Show. E. himalaicus was exhibited in good form last year by Mr. Smith of Newry, spikes of pure white flowers, which is said to be not difficult to grow. E. Olgæ is the latest flowering. I have seen it once exhibited by Mr. Ware at the Aquarium in September, and was much struck by its singular beauty. E. Bungei, another beautiful species not quite so tall. There is, of course, a difficulty about exhibiting, an amateur hardly likes to deprive his garden of so grand an ornament for the sake of the exhibition table.

GYPSOPHILA PANICULATA.—I have before now spoken of this as so valuable for cutting for bouquets, and my object is mentioning it now is that my plant is finer this year than I have ever had it before. Supposing, from its name, that it was a lime-loving plant, I put a considerable quantity of chalk among the roots, but whether its vigour is to be attributed to this or to the hot dry season I cannot tell.

ARNEBIA ECHIOIDES.—Whether it is to be attributed to the dry season or not I do not know, but this plant has flowered well with me a second time, and its bright yellow flowers with brown spots render it a pretty object either in the rockery or border.

ERYNGIUM AMETHYSTINUM.—There are few more striking objects in a border than this Sea Holly with its beautiful metallic blue lustre on leaves, stems and flowers; but one must be very careful in handling it, for the Noli me tangere is much more applicable to it than to the Thistle which Scotland has taken as her emblem. There seems to be some confusion about plants of this genus. Are they biennial or perennial? I have a plant under the name of giganteum which, however, is not nearly so tall as amethystinum and has whitish flowers, but on turning to Messrs. Paul & Son's catalogue I find that variety described as blue. This, however, seems to me at any rate, to be a biennial; then there is alpinum, which I have not grown, but which is said to be very pretty. It is difficult to arrive at the names of plants by the colour of their flowers, for botanists seem to have a contempt for this portion of the description, and I have seen plants very accurately described so that they were easily recognisable, but, alas! when the colour was spoken of it was entirely different.

ASTER BESSARABICUS.—I give this name with some hesitation to a very beautiful variety of Michaelmas Daisy, which has been in flower in my garden for some time. I say with hesitation, because it seems almost impossible to arrive at a correct nomenclature. variety which I have under this name grows to a height of 2 feet to $2\frac{1}{2}$ feet; the flowers are large, and very freely produced, of a bright purplish blue, with a yellow centre. There are many others of the family now coming in, but I think it hardly necessary to note them, for it might happen that the names by which I have received them may not be correct; but most of them are desirable plants at this time of the year.

AMARYLLIS BELLADONNA.—However trying this past summer may have been for herbaceous plants and many Lilies, it has unquestionably suited this autumn flowering member of the group. My own bulbs, planted in the front of a greenhouse facing south, are flowering more freely than I ever had them before; I, however, saw the other day in a friend's garden near here some grand clumps in full flower, reminding me somewhat of a long border in a garden at Bray, in Ireland, which at this time of the year used to be one mass of bloom. Like some other of the family, it requires a warm sheltered border, and also prefers to be let alone. Any ordinary garden soil seems to suit it.

ZEPHYRANTHES CANDIDA.—The dry summer also seems to have suited this delightful little bulbous plant, which is not so often seen in gardens as it ought to be. Its habit is dwarf, the foliage small, and the pure white flowers freely produced. Light and rich

soil seems to suit it.—D., Deal.

CYPRIPEDIUM CHARLESWORTHI.

One of the most distinct Cypripediums of recent introduction was exhibited under the above name at the last meeting of the Royal Horticultural Society by Messrs. Charlesworth, Shuttleworth and Co., Heaton, Bradford, and a first-class certificate was awarded for it. C. Charlesworthi (fig. 43) is a new and beautiful species introduced by the above mentioned firm from the East Indies. It is very dwarf, with long narrow leaves. The flower stem is only 3 to 4 inches long. The lip is short, green, heavily suffused with bronzy brown, and the dorsal sepal is very noteworthy. It is broad and rounded, and the colouring is a beautiful soft rose, delicately veined. The staminode is pure white. A feature of the leafage are the rows of dots on the reverse side. The species is a great acquisition, and will become popular with Orchid growers.

REPOTTING AND SURFACING COOL HOUSE ORCHIDS.

THE present is perhaps the most suitable month in the year for a thorough overhauling, cleaning and repotting, or surfacing as the case demands, of the plants in the cool house. There is a time when all healthy Orchids put forth a flush of young roots, and in the case of Odontoglossums and kindred plants it is usually at this season when the growths are approaching completion. This is the time that Orchid growers should give fresh sweet compost for the new roots to take to at once. It will give the plants a hold on their pots that will stand them in good stead during a long dull winter, and will also assist them materially in swelling up fine healthy pseudo-bulbs.

Masdevallias of the Harryana, amabilis, and Veitchi types, though many prefer to repot in the spring, would often be more easily wintered if given new compost early in the autumn. The soil is frequently in such a fine and close condition after the repeated and copious waterings necessary to their well-being in the summer months, that unless watering is judiciously performed the plants lose the greater portion of their roots in the winter. This is a serious check to the plants, and can only be avoided by keeping the compost in a sweet and open condition, and providing good

drainage.

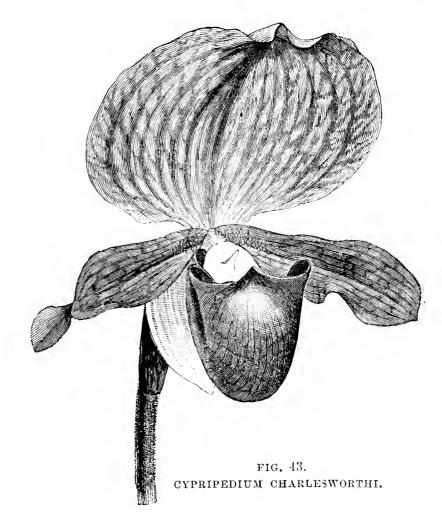

The mode of potting these useful Orchids has often been referred to in the Journal of Horticulture, so that it is only necessary to say that clean pots of as small size as possible should be used, in no case allowing for more than about an inch of compost around the old material. Fill two-thirds of the depth with drainage, use some clean moss as a film, and plenty of finely broken potsherds mixed with the compost. Plants that have the drainage in thorough order and do not require larger pots should have a little of the surface soil removed and fresh compost dibbled in where necessary. After the plants have been thoroughly cleaned, and before they are returned to the house, the stages, glass, and walls should be well cleaned as advised by "Specialist" on page 215.—H. R. R.

OUT OF TOWN.

Worksop in the summer is made lively by ever arriving excursionists. They come from all parts of the country, but the manufacturing districts chiefly, for a visit to the Dukeries. Conveyances of all kinds are crowded, and choral parties sing happily on the way. Glad enough are Sheffield and Manchester workers to get

out of town, and they are out of it very decidedly in the glades of historic Sherwood. The freedom that is granted is a boon to the thousands who avail themselves of the privilege afforded. There are only two Dukes in the district now, but there once were four—the Duke of Norfolk, Worksop Manor, now belonging to John Robinson, Esq.; the Duke of Kingston, Thoresby, now the seat of Earl Manvers, with the Duke of Newcastle, Clumber; and the Duke of Portland, Welbeck. Of the two latter estates the ducal owners are still young, kindly disposed to all and more than popular; yet not more respected than is our guide, and surely no better guide there could be, for Mr. Machin can go anywhere and is everywhere welcomed in the district.

We have a "long day" before us, for Welbeck, Thoresby, and Rufford have to be visited, and then there is a drive of several miles to Southwell. The squire brought a good horse and comfortable wagonette, with something in it, and away we sped on our journey. We skirted the ancient manor of Worksop, embowered in trees, the estate being richly wooded, and in the course of half an hour drove right into the kitchen garden at Welbeck, for the garden "walks"

are carriage drives, in fact everything, seems great about it. The kitchen garden certainly is, for enclosed are thirty acres, and the glass structures are in keeping; then if we look beyond to the huge stone buildings, riding school, and others, with dozens of detached villa-like residences, we have to feel that Welbeck is not as other places are. It is distinct from all above ground and still more so beneath it, and though it cannot be said to be beautiful it must be regarded as wonderful. But we cannot explore, and only a quick rush through some of the houses is practicable while the wagonette is waiting. Mr. Horton was luckily at hand, and we were at ease with him in a moment. He has been nineteen years in the gardens, and has a clear firm grip of his great charge. The demands of the establishment are enormous, and a cart is always at work taking produce from the gardens to the Abbey, but very unlike an Abbey is the huge square pile which stands out bleak and bare with never a tree on the wide expanse of lawn in front of it.

We race through a large vegetable house, onwards through figgeries, peacheries, vineries, and planteries, tropical and otherwise; now we are under a rich canopy of Bougainvilleas and Allamandas, with beautiful decorative plants all around, and anon in one house or another amongst apparently all kinds of fruit grown in this country, but not in all places so well as at Welbeck. Glass ranges 100 yards long appear to be plentiful, and, large as they are, look small when we enter others twice or nearly thrice that length, and all well and profitably occupied, while cleanliness and good order are prevalent everywhere. The pink "Malmaison" is the favourite flower of the Duchess, and great provision is made to meet the daily demand all the year. We entered not the famous underground tunnels, but were content to peep into one above ground, an arcade of Apples and Pears, probably nearly 300 yards long, and then after keeping our

distinguished coachman waiting too long, and doing no sort of justice to the work of a genuine gardener who knows his business and does

his duty, we sped away to the forest.

Soon were we among the Oaks, on some of which the sun has shone for centuries, the Greendale Oak having stood its ground for more than a thousand years, so, no doubt have other of the giants of a far past time, but now mere shells dwindling to decay, yet some of these ancients still fruitful. As we pass along the broad green glades, dodging the flies as best we can, it was pleasing to note the young plantations duly "labelled" with the date of sowing, and the names of the historic trees from which the seeds were gathered; and what striplings were these trees of thirty of forty years old in comparison with their ancient progenitors! Vast as is this expanse of woodland, yet all around we see evidences of care, of love, and of labour in keeping everything in order, yet retaining the characteristics of the sylvan scene.

Eventually, after sundry turnings, as if tracing our way through a gigantic maze, we emerge into the open country and are soon passing through the pretty village of Edwinstowe, a village of refreshments it would seem to be judging by the invitations to tea, luncheon, or modest hot water in windows or garden tablets all along the line, saying nothing about everything else you may want and are ready to pay for, from bread and cheese to a champagne dinner, from a saddled donkey to a four-in-hand coach. good reason to be proof against all such blandishments we enter the forest again and meet a stream of tourists wending their way to the general commissariat. We are soon driving round and admiring the Major Oak under which "parties" are resting, enjoying the shade and mid-day meal. This noble tree will shelter many, for the circumference of its spreading branches exceeds 700 feet. It stands alone on an open plateau of grass, a truly majestic specimen of its kind, and though its huge trunk is said to be hollow the branches appear to be as healthy and the leaves as green as those of young trees not over a century or two old, these in turn being as fresh as thousands not long since out of their teens. The soil, at least on the surface, is sandy and poor, but there must be something better below to support the magnificent arboreal vegetation through which we pass to Thoresby, which is not very far from the "Major.

The drive after entering the demesne is grand almost beyond description, at least to those who admire gigantic Oaks rising from an undergrowth of bracken, the trees standing far enough apart, probably 50 or 60 yards, for showing their individuality, massive trunks, and noble heads. There is no formal avenue of them, or anything approaching thereto, but they stretch away on each side in picturesque irregularity. Thoresby has been described as the "Queen of the Forest," and certainly the view from the comparatively new, large, and ornate mansion, of boldly undulating park, with distant tree-clad hills and pastoral dales, of river and lake, and herds of deer, is in its scope and diversity a scene to be enjoyed and remembered. Yes, it is a queenly place is Thoresby: but we arrive at the gardens, long behind time, and almost "given up" by the genial gardener, whose name is familiar in the horticultural world through long and excellent work in gardening, for who has not heard

of "Henderson of Thoresby?"

"Come in and have some dinner; it has been a long time ready, and not now as we should like it, yet there it is and a good welcome." Such was the greeting. "No, no, Mr. Henderson, many thanks, we are foresters to-day, and our repast must be on the green sward, and our canopy the greenwood tree." He could see we were well provided for when it took two men to carry the luncheon basket for three, and our friend stepped aside with a quiet smile. We feasted as Robin Hood never did on venison pie with the sparkling accompaniment of Moses and Aaron—the old waiter's phonetic rendering of some such sound he had heard as Moët and Chandon. No, the mystic Robin had none of this, though he is credited with a liking for nutbrown ale. But as all things come to an end so did our little pic-nic, and one man could then easily carry the basket into the boot of the

Now to the gardens. As at Welbeck, so here, we could only have a quick march past much that was good to see, and not an inspection. Outside, the crops were suffering from drought more than any others in the Dukeries, as the soil is light and sandy. It is this light soil which renders fruit growing no easy task in the houses, but with the best cultural attention a full and good supply is provided. The glass ranges are extensive, and in them Grapes are produced of excellent Peaches and Nectarines are extensively and admirably grown, while of Figs the supply is bountiful. As showing the influence of soil on Vines Mr. Henderson had by special effort procured enough of a substantial kind for one small vinery border, and the effect was most telling, displayed by growth, foliage and fruit, but sufficient for all the long ranges is out of the question and not really needed, for the fruit is as good as is desired for table, and Mr. Henderson would not increase his fame as a gardener by growing for and winning more prizes at shows. Plants are extensively and

well grown for decorative purposes; the terrace flower garden was highly attractive, young Conifers flourishing, indeed almost growing too fast for each other, and everywhere cleanliness and good order added to the enjoyment of this well appointed and well

After a short rest in the pleasant home of the gardener, who has worked so well for thirty years in his fine charge, and kind attention from Mrs. Henderson, we had to leave Thoresby all too soon, knowing that at a village inn another carriage was waiting. We had there to part company with the generous friend who had done so much for us and whose name will be held in grateful remem-

brance, Mr. Henry V. Machin of Gateford Hill.

Mr. Henry Merryweather now takes the reins, and we make a dash before dark for Rufford Abbey, the seat of Lord Savile, whose gardens are so admirably managed by Mr. R. Doe. Here we found the finest collection of hardy fruit seen during the midland explorations—hundreds of dwarf open bush Apple and Pear trees, models in their way. The varieties had been allowed to assume their natural character, but the branches wide apart standing quite clear of each other, the best of all ways for having them studded with blossom buds their whole length, to be followed by ropes of fruit from base Many of the trees had grown too freely and had to extremity. wisely been lifted, a great work with so many from 8 to 10 feet in diameter, and the work of watering during the roasting summer had been the reverse of light. But there is plenty of water at Rufford, for a beautiful stream runs through the gardens and is made to It was from here that the very form an ornamental feature. symmetrical Beauty of Stoke Apple came that was certificated at Westminster two or three years ago. The tree is excellent in habit,

a good bearer, and Mr. Doe has kept fruits till June.

We run hastily through the houses, for daylight is departing, and

notice Vines in admirable condition bearing valuable crops, Gros Colman established on the Muscat gaining in flavour by the connection. The Vines in one house were lifted, the border cleared out, a new one made, and replanting done after they had started growing and were showing bunches in the spring. This was occasioned by a horde of rats taking possession of the border, and they could not be extirpated in any other way. Notwithstanding the ordeal through which those Vines had passed they were ripening an excellent crop of fruit, good proof of the capacity of the cultivator. Peaches are extensively, and it must be added splendidly, grown at Rufford, and it would be hard to find trees in a better state for bearing full crops of fine fruit. Mr. Doe is also famed as a Tomato The plants are grown in boxes about 3 feet long, made with 11 inch deals, five or six plants in each box, and trained up the roof of a span-roof house. They bear enormous crops and seem proof against disease, though many varieties are grown for testing with the standard sorts—Hackwood Park and Ham Green. It would be instructive if Mr. Doe could find time to record his experience, but he is a busy man-always at work whatever the hour may be when work needs doing. Near the mansion, a huge pile, a large lofty winter garden and museum has been erected. It contains splendid Palms, which could only have been obtained at great cost, but no man is to be envied in having to grow them in a structure so unfavourable to their well being, and if Mr. Doe cannot succeed with them the case will be hopeless. Near the winter garden is a huge Walnut tree which "some folk say" is the finest in England. Its trunk girths 28 feet, so now if any reader can find a finer he may send the dimensions to the Editor. The pleasure grounds are extensive, but the lawns were "burnt up," and flowers in the beds struggling against the heat. Yet, great as this was, beds of a white seedling Pansy in the kitchen garden were a sheet of flowers. The pure white Princess Alice Stock was also fresh and extremely beautiful, far eclipsing all others and worthy of being tried in many gardens.

That is all that can be said about Rufford and the work of its undoubtedly able gardener Mr. Doe. The darkness deepens, the clouds thicken, and the hoped for rain comes down; we have a ten miles treat through it, are distinctly "out of town" and go on our way dripping yet rejoicing to verdant Southwell.—A CITY MAN.

PEARS VERSUS PEACHES.

THE article on this subject (page 259) was interesting, and the reasoning in every way much to the point. The question which "C." there brings forward is of the utmost importance, and the remarks of your correspondent should be carefully perused by all who want to make the most of the space at command. At one time there were many gardens in which Peaches used to be well grown out of doors, but at present such are exceptions to the rule. Seldom does the crop prove a profitable one, and taking the seasons together hardly pays for the labour expended.

The times seem to have changed considerably, and a wall of outdoor Peaches would in the long run fall far short of one filled with cordon

Pears of such varieties as Jargonelle, Williams' Bon Chrêtien, Souvenir du Congrès, Pitmaston Duchess, Doyenné du Comice, Marie Louisc, Beurré Dicl, Thompson's, Prince Consort, Glou Morçeau, Easter Beurré, and other good sorts. Against the few gardens where Peaches do well outdoors, how many have walls with trees trained to them just merely languishing out an existence, and which no amount of skill and intelligence on the part of the gardener can ever make them bring forth satisfactory results? Instead of devoting a whole wall with Peaches it would be better to build either a second loss to be a second lo would be better to build either a case or a lean-to house on a part of the wall, and fill the remainder with cordon Pears. I mention cordons because they are admirably adapted for walls, and much variety may be grown in a limited space. Many more and finer fruits of Peaches could be obtained from an unheated house, although probably not taking more than a quarter of the wall space, in a few years than would be gathered from an outdoor Peach wall in a lifetime.

An instance might be cited. A south wall 120 yards long at one time used to be occupied with Peach trees, a fair crop being the result about every three or four years, and this with every care being taken in their cultivation. My late employer not being satisfied with the results the wall was made 3 feet higher, and a three-quarter span-roofed house 130 feet long erected. The best of the old trees from the wall were selected, and planted alternately with young ones. From the old trees we had a fine crop the first season, and when the young ones wanted more room the former were moved. My employer remarked that in the My late employer not being satisfied with the results first four years he had had more Peaches and Nectarines than from trees grown out of doors in twenty years. The remainder of the wall is now planted with espalier trained Pear trees—it being too low for cordons and these add very materially to our supply of fruit. I have no desire to say that good Peaches cannot be grown outdoors, but in this district (Liverpool) they may be nearly counted on the fingers of one's hand. Good Pears would appear to find a ready sale, for the finer samples of Williams' and Pitmaston Duchess have been selling in the leading Liverpool fruiterers' shops at 3d. and 6d. each,—R. P. R.

THE subject discussed by "C." (page 259) as to whether south walls may be the more profitably utilised for the production of Pears or of Peaches admits of some divergence of opinion. A few days previous to the appearance of the article alluded to I happened to call on a gardener who has under his management south walls planted respectively with Pears and with Peaches. The former were so much in evidence that I remarked in passing they would surely net a larger sum than the latter. But, no! good Peaches at this season bring fair prices, and fine as many Pears are, there are still Peach trees in existence which produce year by year good crops of fruit.

With the general tone of the article in question one is only too pleased to agree. I am hampered with old trees which have changed proprietors so often that they are veritable heirlooms. They are too old to be depended on, are only intermittently fruitful, and never produce fruit of the best quality. For my own part, I should be only too pleased to burn, not all, but nearly every old tree in the garden, root and branch, to be in three to five years in a position to produce with certainty more and better fruit than it is possible to get from our present stock. is, I believe the one reason why Peach growing in the open has declined so much—viz., old trees which proprietors will not allow to be destroyed and replaced by young ones. I know trees that are now doing duty which thirty years ago were aged. Is it reasonable to expect the best or even average results from these? I think not.

It is, however, a point worth considering, whether too much space is set apart to Peaches to the exclusion altogether of Pears from south walls. In an ordinary family the requirements of fruit at one time are, as a rule, not difficult to meet. In my own case I have kept an uninterrupted supply of Pears for over two months almost entirely from a few small trees, and some of these single cordons. The larger of the trees have yielded so much fruit that some had to be sold. In the same way for some time back I have been getting occasional dishes of Nectarines and Peaches from a few trees growing on the low front wall of a plant house. So convinced am I of the utility of a number of small trees that for a few years back I have been planting cordons and

other trees on vacant places on walls. Even with Peaches I do not consider it necessary to go to the trouble and waste of time necessary to lay the foundation of a huge fan-shape tree. If the situation, climate it may be called if that seems a better term, does not suit, it is easy to keep a supply of young trees to take the places of those stricken down. If they never get very large one has less compunction at being under the necessity of removing them.

With Pears it is somewhat different, for on a south wall a tree can be grown to a large size and continue fruitful for many years. here again the question crops up whether it is desirable that a large tree of one sort ought to be grown, or, in its place, several small ones? Many varieties of Pears should be cultivated provided the sorts grown are of good quality. It is, however, not uncommon to find choice varieties limited. A few large trees cover the wall space and there the matter ends. I am referring to the northern parts of the island. But we have now so many Pears really worthy of cultivation that instead of extending the size of large trees we ought rather to increase as much as possible the number of varieties and limit the size of the trees. At present one has a choice of such good sorts as Williams' Bon Chrêtien, Souvenir du Congrès, Beurré d'Amanlis, Louise Bonne of Jersey, Dr. Hogg, Fondante d'Automne, Flemish Beauty, and Belle Julie. Each

of these is in flavour distinct from the other, and one might go on enumerating a long list of sorts to which the same remark would apply. Therefore it can be no loss to limit the space devoted to Peaches, to growing fewer of these, or rather, I should say, to producing smaller trees; and where it is not already done substituting for them medium-sized Pear trees in as many good varieties as it is possible to find room

HAVING returned after a quarter of a century to the same neighbourhood in Somersetshire that I formerly occupied, I looked forward to repeating my pleasant successes of the past in growing Peaches. Accordingly last autumn I filled some empty places in the wall with Noblesse and Sea Eagle, my landlord, "distance lending enchantment to the view," dilating on the size of the Peaches that used to flourish on that wall when he was a lad, where now other tenants had filled vacant places with Pear trees and Plums. Having then planted the Peach trees and taken them under my own special protection, and into the bargain being considerably proud of their appearance, picture my the bargain being considerably proud of their appearance, picture my feelings on reading a fortnight ago that my work was all "Love's labour lost," and that I had much better have put in some Pears! Such a dictum did not at all agree with my own feelings. Certainly the memories of the past painted the Peach trees as more prolific, fruit for fruit, than the Pears. Then I had Noblesse, Grosse Mignonne, and Barrington, and the two former were certainly more fruitful than the Pears Forelle, Beurré Rance, Napoleon, although Williams' Bon Chrêtien, Jargonelle, and Beurré Diel generally equalled in number the stone fruit, the latter a very handsome Pear to look at; but "handsome is that handsome does" applies to it in my opinion, for I consider it in the raw state a worthless fruit, and one that I should never burden my walls raw state a worthless fruit, and one that I should never burden my walls with unless I possessed some hundred yards of the same. I cannot understand its being styled "melting." Of the many fruits that I have tasted I have never met with one that deserved the title of Beurré. All were disappointing.

I have every regard for a really good Pear, it is a splendid fruit; but in my estimation it never could equal a good Peach, although I grant I have heard not a few persons maintain the contrary. Well, as our neighbours say, "Chaçun à son goût;" but even this does not entitle us to advise setting Pear trees in the place of the Peach, or to writing almost as if the latter was of little value. I have little doubt, then, that friends of the Peach will, like myself, feel relieved at the timely words of such an authority as Mr. E. Molyneux (page 287), and so I

gaze at my young trees and urge them to go on and prosper.

My small experience as to "blister" agrees with that of Mr.

Molyneux; it does not prevent a fair crop of fruit, but doubtless this would be altogether better without the infliction. I used to set to work and pick off these bloated specimens of foliage and get rid of them. know that it is often attributed to east winds, but I have always felt that this was somewhat mythical. Is east wind really the cause l wonder what Mr. G. Abbey may say to this. I have always fancied that there is something of the mildew character about it, and that there are If this be so there would be more reason for destroying it as soon as detected. Under a fairly strong poeket magnifier it looks like some sort of efflorescense over the swollen and distorted leaf.—Y. B. A. Z.

I AM quite sure Mr. Molyneux (page 287) will find many readers who will agree with him in his opinion as to the relative value of Pears and Peaches. Those who have gained experience in the marketing of such fruits are best able to judge which may pay the better price, and as Pears may be grown quite as well on other aspects it seems a pity to utilise south walls for these at the expense of Peaches or Nectarines. Either for market or private use Peaches are a summer and autumn crop, and for a just comparison Pears that ripen at the same time should be reckoned with as occupying the position in question—namely, south walls. Early summer Pears certainly cannot claim a very great value because of the short period under which they may be kept sound; and in the autumn there are plenty to be had from garden and orchard bush and standard trees which will reduce the value of wall-grown fruit however good it may be. In the autumn, too, there are, as Mr. Molyneux points out, the French and Jersey Pears to be reekoned with, and it must be indeed good English fruits that can compare with these both for colour and size.

The unpopular opinion that has obtained in so many gardens as regards outdoor Peaches is due more largely to want of proper attention in the matter of spring protection, pruning, and thin training of the branches than any other cause, although it must be admitted that every garden is not absolutely suited to their requirements. Late sorts are not always remunerative, and should be replaced by those which ripen their crop in time to do some pruning before the sunny days are entirely gone. If early and midseason sorts of good repute were chosen more freely for growing outdoors I am inclined to think there would be less cause for complaining about Peaches. Very late sorts, such as Salwey, Golden Eagle, and Lord Palmerston, may help to form variety; but my experience of them is that they are treated more as an ornament to the table than as a dessert fruit by those who know them. It is useless for me to send them to table in a raw condition here; they must be cooked before they are considered acceptable at the table. I am referring, of course, to these Peaches in their proper season—October.

Although I have seen several excellent walls of Peaches outdoors, I think the best was under Mr. Robinson's charge at Heywood. There were plenty of fruits there of Walburton Admirable, Princess of Wales, and Demond weights and Demond and Dymond, weighing 10 ozs. each, the colour and quality being superb. I am quite sure there would be no comparison in the value of a Pear crop occupying the same amount of space as these Peach trees, even if

they were valued at a lower rate than that quoted by Mr. Molyneux; and I am convinced that more than one adverse season must occur before Pears will be accepted and adopted as a more appreciative and paying crop. At Marston a failure in outdoor Peaches is almost an unknown thing, and this year Mr. Iggulden gathered several dishes of fruit in June, and a heavy crop was borne by every tree under his charge. Strong as he has frequently proved himself in Pears, he would not be guilty of filling his warm south walls with these. I have found that an east aspect is better suited than a wall facing west for growing Peaches outdoors. They do not obtain the same amount of sunshine in the latter position, and consequently their wood does not ripen so perfectly, particularly where the walls are lofty. Nor do the leaves blister so badly as a rule in the spring, sometimes not so much so as they do on a southern exposure.—W. S., Rood Ashton.

WEMBLEY PARK.

Wembley Park, the most important of the latest additions to the lungs of London, is situated on the north-western side of the metropolis midway between Neasden and Harrow-on-the-Hill. A new station has recently been opened there, it is thus within easy access of the city, and can be reached in twenty minutes from Baker Street on the Metropolitan Railway, travelling by the Aylesbury line. Although comparatively close to London the whole district at present has a rural aspect, which adds a charm to the surroundings of a picturesque park. At one time Wembley Park formed the grounds to a private residence, but the whole of it was purchased a few years ago by the Metropolitan Tower Construction Company to provide a pleasure resort, including a feature of a unique character. The latter will be known as the Wembley Park Tower, which will doubtless prove a powerful attraction. It is not within the province of a gardening paper to go into details regarding this wonderful example of engineering, but when a Journal representative gazed upon it a few days ago he came to the conclusion that when completed it would be a stupendous erection. It will exceed in altitude by 175 feet the famous Eiffel Tower in Paris, the latter being 955 feet in height, whilst the tower at Wembley Park will be 1150 feet high. It stands on a hill, so that when completed the summit of the erection will be 1300 feet above the sea level. Already the four huge buttresses covering over 2 acres of ground have reached a height of 100 feet, and it is anticipated that the tower will be completed in eighteen months. It will weigh about 7500 tons, and on the three platforms there will be a concert hall and numerous other attractions.

The grounds, however, concern us most here, and, attractive as the Tower is, a brief description of the manner in which these have been laid out by Mr. H. E. Milner will perhaps be more interesting to readers of this paper. The Park is about 130 acres in extent, has an undulating surface, and is remarkably well wooded. There are some fine Oak trees standing in clumps and singly in various parts, and these have been preserved and shown to great advantage by Mr. Milner. On entering from the railway station the visitor's attention is first attracted to a picturesque lake which covers 8 acres and has an uniform depth of 3 feet. This is fed by the river Brent, and the scene has been enhanced by the erection of pretty bridges and the formation of islands. One of the latter is planted with Bamboos, which will form a striking feature when established, as also will the splendid clumps of Golden Elders and other shrubs on the banks. On the north side of the Park there is a wood which will be a charming retreat, and a main road is carried round the grounds until it reaches the Tower. The walks and roadways are laid out in a manner that gives evidence of a masterly hand, the grand sweeps and curves being most conspicuous. Fine groups of shrubs of different kinds have been planted in suitable places, and these have already made good growth. In front of the principal refreshment pavilion a splendid terrace has been formed. This has a bold walk through the centre, leading from the building mentioned to a band stand and then sweeping on each side to other walks. Flower beds are being laid out on the terrace, and these will in due course be devoted to the latest phase of bedding. The principal pathways are bordered with shrubberies in places, and amongst other plants some clumps of Hydrangea paniculata are noticeable. It is obvious that the most has been made of everything. There is nothing petty discernible, but everything is of a bold and sweeping nature which always characterises the work of a good landscape gardener.

Apart from the features mentioned there are others of a more important nature perhaps in the athletic world. Cricketers and football players will be glad to learn that Mr. Milner has formed a splendid ground, which is already in request, as the Old Westminsters, one of the leading amateur clubs of the south, have arranged to make Wembley Park their headquarters this season, the first match probably taking place on October 14th. A magnificent running track, having only two laps to the mile, encircles the cricket ground, which is also bordered with groups of shrubs tastefully planted. Many other similar things are provided, and al fresco entertainments of various kinds will be given when the Park is opened to the public, as it will be shortly.

TUBEROUS BEGONIAS AS BEDDING PLANTS.

I READ with some surprise the sort of half prophecy that "W. P. W." (page 264) is inclined to make anent the future of Tuberous Begonias as bedders. With me they have this year done even better than in other easons. Perhaps it may be the situation that is in favour of a free

growth and abundant blossom. Our best display of these plants is in a bed occupying about a hundred tubers, some of them six years old at least. Dotted here and there amongst the Begonias are Eucalyptus globulus, Ricinus cambodgensis, and Abutilon Thompsoni, with the object of giving relief to the otherwise formal surface. No doubt the latter plants have provided an agreeable shade to the Begonias, as the Eucalyptus and Castor Oil plants are now 6 feet in height. The Begonias have grown fully 2 feet high, have flowered profusely, and are doing so at the present time (September 25th).

In spite of the popularity of Tuberous Begonias as summer bedders, and the ease with which they can be grown, I fear many persons do not manage them as well as they might. Too often growers neglect to provide some slight shade for a week or two after they are planted, if the weather be hot and dry. Some plants receive a check at that time from which they do not recover during the summer. As planting proceeds I provide a slight shade by thrusting in a few green Sycamore or Chestnut boughs amongst the plants. The soil is then kept cool, and plants under such conditions quickly become established. The covering of the soil between the Begonias with some low growing plants such as Sedum Lydium, S. glaucum, or Herniaria glabra is too often neglected, and in a hot season as that just experienced the advantage of so doing has been demonstrated. Not only do they provide an agreeable contrast between the various colours of the Begonias and themselves, but they arrest the evaporation of moisture from the soil by the sun and keep the roots comparatively cool. I have at the present time a very fine display of these Begonias from plants that were raised from seed sown early in February of this year.—E. MOLYNEUX.

BEGONIAS AT FOREST HILL.

To see Begonias in beds everyone should at once pay a visit to Messrs. J. Laing & Sons, Stanstead Nursery, Forest Hill. Catford Bridge, on the South-Eastern, and London, Chatham, and Dover Railways is the nearest station. Those who go will be astonished at the magnitude of the undertaking, a plot of ground over two acres in extent being entirely filled with double and single varieties. The number of plants required for this purpose reaches almost to the stupendous total of 350,000, and it cannot easily be imagined what a spectacle is presented to the eyes of visitors. The plants have this season, as everyone well knows, been terribly handicapped by the dry weather of the past summer, so that now the number of flowers expanded amount to about that which one might naturally expect to see during July. The plants, too, have not made the growths which usually characterise well managed Begonias, nevertheless they are strong, dwarf, and carrying large numbers of excellently coloured, perfectly formed blooms. Bright and beautiful, a picture of health, and an example of untiring intelligence and energy, is this wonderful sight. When we have a bed of Begonias consisting of say 200 plants, we think we have a brave show indeed, and if the plants are healthy and well flowered we are proportionately proud of them, but when we see them by the acre we are able to appreciate them in a larger degree.

The plants have been placed in beds, each containing one distinct colour, and considering that the plants are seedlings it is surprising how tew rogues there are to be found. Here and there amongst the scarlets one sees a pink or a white, but so far from detracting from the beauty of the display they but accentuate the good points by their minority. First comes five beds of dark crimson sturdy little plants, having numberless faultlessly shaped blooms on them. Next came five beds of a very bright scarlet-coloured variety, and which formed, in my opinion, one of the brightest spots in the whole collection. Some beds of a soft pinkbloomed kind attracted me next, then crimson again, after which came a rose-coloured variety of a high order of merit. The yellows were showy, and the whites looked charming in their chaste purity. Those already mentioned belong wholly to the single section, and occupied about half of the space allotted to the Begonias, the other half being devoted to the double varieties, which had been planted in the same manner, but did not present such a show of bloom as did the others, as many of the best had been lifted in order to preserve them from the frosts, which may now be expected at any time. Notwithstanding the fact that many had gone, some grand plants are yet to be seen, and foremost amongst which were some whites of exceptional quality. They carried their blooms in an upright fashion, allowing the pureness of the white and the perfect contour of the flowers to be seen at a glance. No fault could be found when they were closely examined; on the contrary, the more one looked the better the flowers appeared to Then, too, were noticed some scarlets, crimsons, and grand become. yellows, forming a perfect galaxy of beauty.

Conspicuous amongst those that had been placed in pots were some plants having blooms of pleasing colours. As is well known the Tea Roses of the L'Ideal type afford some of the most beautiful combinations of shades one can wish for, and which are practically indescribable. Such is now the case with the Begonias. Yellows can be clearly seen, as also can rose, pink, scarlet, and crimson, and occasionally other shades, so that I may be forgiven for not putting the colour down concisely in one word. However, the flowers in those shades alone are worth a run down to Forest Hill, for they are really exquisite in their delicate colouration. Those who are wishing to see these beds this season will do well to make their pilgrimage at once; they will be cordially received I do not doubt, and will be amply rewarded by the veritable feast of Begonias which will greet them as brightly, if not as heartily, as will either of the Messrs. Laings.

A brief reference to the Begonias in the houses must be made. I can but repeat what has been said so many times before, and that is that they are "perfection." What more can be said? What more can indeed be necessary? and I must let it suffice; let those who are sceptical take the advice given above, and go to see and judge for themselves.—H. J.

INWOOD HOUSE GARDENS, BLANDFORD.

Through Mr. Wilkins' untiring energy, Inwood House Gardens, Blandford, have obtained very high reputation. It is not a place of one thing, a garden of one variety. Everything is well done here, and whilst vegetables have created the greatest interest, plants and fruit are finely grown also. I do not know whether it is just to class Mr. Wilkins as the champion vegetable grower of the kingdom. Some may take exception to that high estimate. But all the same, as an average grower and exhibitor of vegetables, I do not know of his superior, and certainly very few are his equals. However, his record of successes tells its own tale. It is proof that is incontrovertible. Even the best of growers, the most successful of exhibitors, has to take a back seat sometimes; but that is not due to want of ability, but rather to the aecident that just then products are not at their best. When, however, a grower exhibits, and takes the highest aggregate of prizes for vegetables all over the kingdom from June to November, it is evident that such a grower is entitled to the designation of champion. But Mr. Wilkins is not at all a proud man. He is very human so far, that nothing makes him egotistic or elate. He bears honours and reverses with simple ease, and still remains what we rejoice to find is so largely the characteristic of the British gardener, even when on the competitive war path—a plain, homely, intelligent, and most amiable man.

Inwood House gardens are not old, indeed have all been made during the past ten years, and entirely under the present gardener, who came expressly from Motcombe to undertake charge. The situation is an elevated mound or hill, on a base of limestone or sandrock, with a very shallow surface soil. Of course it would have been useless to expect to construct a good garden out of such material, and therefore the upper crust or layer of this rock had to be excavated; a heavy work that was well done, and the bottom made up with soil brought in from anywhere, hence the present depth, the luxuriant growth seen in all directions, and the magnificent produce which has made Inwood so famous. gardener's house is reached by a ride of some two miles from Templecombe Junction, but that hospitable place is still fully one-third of a mile from the gardens, a distance that has some disadvantages and some advantages. Trees are not on such a shallow soil of the most robust order, and that is largely the chief weakness of the place. Get in the kitchen garden, however, and then everything is almost

The plant houses are numerous, and include in their contents a very large number of grand show specimens, foliage and flowering. collection is remarkably extensive, and the bulk of these is found in a long span-house of horseshoe shape, some 200 feet round, literally crammed with plants, above and below, for beautiful climbers here grow as if in their native habitats. Of specimens there is a gigantic Latania borbonica, with huge leafage spreading to an area of 30 feet. This stands on a pedestal in the centre of a large basin of water. There are many other Palms, Ferns in great variety, and fine plants—Allamandas, Clerodendrons, Bougainvilleas, Stephanotis, Lapagerias, Ixoras, Crotons, Chorozemas, Statices, Eucharis, Alocasias, Cycads, and Kalosanthes, showing that it would be easy to make up a collection of 100 fine samples, or of 200 if needed. Distributed through various houses is a most interesting collection of tropical fruiting or economic plants, such as Musas, carrying grand bunches of fruit; Mangosteen, Monstera deliciosa, the Custard Apple, Anona reticulata, the Papaw tree, showing six fine fruits like large Pears; the Guava tree, which has freely fruited; Vanilla, the Nutmeg, Rose Apple or Eugenia Jambos, Stapelia Litchni, the Coffee tree, which has fruited; the Camphor tree, Camphora officinalis, and others. These show, apart from myriads of plants of all descriptions, that Inwood Gardens is something more than a manufactory for prize vegetables.

I will not refer to the fruit houses because there is not time and space to do so. It is enough to say that vineries and Peach houses are all excellent. Outdoors Pears on bush and pyramid trees chiefly on the Pear stock are truly grand. What a pity some of these specimens could not have been photographed, they would have made almost sensational pictures, especially could the size of the fruit on them have been fully pourtrayed. These trees are situated on each side of the kitchen garden walks, and have been planted from seven to eight years. Hitherto, the soil having been too good, and the growth so robust, it has been difficult to induce them to fruit freely, but this year they have been at their bost. It was mentioned that whilst Pears on the walls suffered very much from the spring frosts, the open trees, being later in bloom, escaped, and set fruit freely. I noted but a few out of the many, though some had had their crops already gathered — Calebasse, Duchesse d'Angoulème, Louise Bonne, Thompson's, Zaphirin Grégoire, Maréchal de Cour, Vicar of Winkfield, Soldat Esperen, Beurré Clairgeau, Pitmaston Duchess, Durondeau, Bergamotte Esperen, and Seekle, these sufficing to show that the collection is a large one. Mr. Wilkins is an enthusiastic mulcher, indeed he says that this dry season he owes so much of the size of his Pears, as of all other crops, to heavy mulchings of stable manure. However, as some fifty horses are kept, and the stables

are close by, manure in plenty may be had for the fetching. A somewhat unique arrangement is that of the walled-in bush fruit garden, over the whole of which in the fruit season strong netting may be stretched, to the confusion of the birds, great and small, whilst from below everything is readily accessible. Here, too, as elsewhere, Chrysanthemums are in very strong evidence, some 600, all in splendid condition, being grown, so that there will be plenty of show flowers if needed, and plenty to furnish houses and indoor decoration.

Vegetables here are so fine that it is difficult indeed to do them full justice. Onions alone merit a page, so grand are the samples and so plentiful are they. Mr. Wilkins has finished his bulbs perfectly, and giant Ailsa Craig, a dozen of which average 36 lbs., the heaviest weight ever reached, are as mature and as handsome as bulbs only 3 ozs. instead of 3 lbs. Although not so fine, yet most wonderful are the selected samples of Rousham Park Hero, Lord Keeper, Anglo-Spanish, and Inwood Favourite, a redder variety, product of a cross between Red Globe and Anglo-Spanish, of the flatter bulbs; and of Cocoanut, very deep globe shaped; Wroxton, a grand keeper; Excelsior, hard and handsome; Advancer, yellowish globe; Sutton's A1, very fine; Jarman's International, Pinesfield, and Somerset Hero, all globe shaped, in almost bewildering profusion. These bulbs are all of the new order, of product transplanted from boxes, the seed being sown under glass in January. Now they are fully ripe and stored on broad trellis shelves in an ancient round tower standing in the gardens, and the Onions are probably the finest in the kingdom. Leeks are yet all agrowing. These comprise the Lyon, Prizetaker, and Champion; but Mr. Wilkins holds that he can have

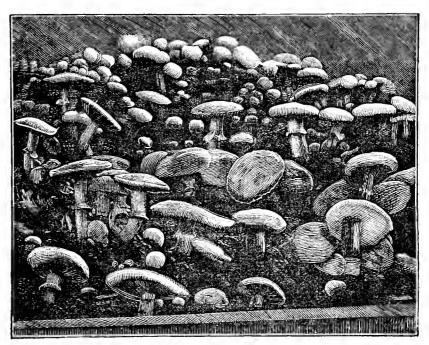

FIG. 44.—MUSHROOMS AT INWOOD HOUSE.

stems long and white, short and stout from any variety, just as they are blanched or otherwise. Some superb Tomatoes of the Perfection type are shown grown on pot plants in a lean-to house that balance other vegetables. Carrots are chiefly now of the Intermediate forms, although Early Gem and Champion or Nantes are grown and largely used for exhibition earlier in the season, when also Asparagus, Sea Kale, and Dwarf French Beans, such as Canadian Wonder and Ne Plus Ultra, are largely grown. Runner Beans are marvellous, several rows of the Inwood selection of Ne Plus Ultra, a beautiful strain, have grown from 16 to 18 feet in height. Cauliflowers are very fine. This most useful vegetable begins with Early Forcing or Snowball, follows with a perfect variety, Sutton's Magnum Bonum, then Autumn Giant and Mammoth, and so the supply extends over a long season.

Parsnips are represented by the Student and Hollow Crown, a large bed being in fine growth; Potatoes by Satisfaction, Sutton's Seedling, London Hero, Snowdrop, Windsor Castle, and International out of many; Peas by Prodigy, Autoerat—this being excellent for dry soils or seasons; and Duke of Albany. Celery for early work and exhibition is chiefly blanched by paper bands and round drain pipes. Veiteh's Early Rose, Standard Bearer, and Aylesbury Red of coloured, and Wright's Giant White and Solid White for pale varieties. Stems weighing 15 lbs. each of Standard Bearer have been produced here after being cleaned and trimmed. Beet is represented by Middleton Park, Pragnell's Exhibition, Cheltenham, Greentop, Sutton's Blood Red; and Brussels Sprouts by Nc Plus Ultra and Exhibition; Cucumbers by Model; Turnips by Dobbie's Selected Model and Snowball. Thus it is seen that the variety is considerable the cultivation of the best, and the product superb. The keep siderable, the cultivation of the best, and the product superb. The keep of the place also is good. Anyone visiting Inwood will go away satisfied that Mr. Wilkins must grow all his produce, for the simple reason that no one else can equal him in production. I might write much more about this place, but the foregoing must satisfy curiosity now; whilst it is a delightful place, the practical gardening in every branch is of the best, and much of it as shown cannot be excelled.—A. D.

[It will be seen by the photographic illustration (fig. 44), which represents a portion of a bed of Mushrooms at Inwood House, that Mr. Wilkins is also an adept in this phase of gardening.]

EVENTS OF THE WEEK.—The Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, S.W., on Tuesday, 10th, particulars of which are given in a paragraph below. On the 11th inst. a three-days exhibition will be opened at the Royal Aquarium, Westminster, under the auspices of the National Chrysanthemum Society.

- —. THE WEATHER IN LONDON.—Changeable weather has again characterised the past week. Sunday was comparatively mild with occasional slight showers. On Monday similar weather occurred, and rain fell heavily during the night. Tuesday was fine and colder, as also was Wednesday morning. At the time of going to press it is bright with rather a keen wind prevailing.
- —— ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday 10th October, when prizes are offered for hardy herbaceous perennials. At three o'clock Mr. W. Crump will deliver a lecture on "Pears."
- THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—As has been notified in our advertisement pages an election of pensioners on the funds of this Institution will take place in January next. Intending candidates must send in their applications on or before October 14th, to Mr. George J. Ingram, 50, Parliament Street London, S.W.
- —— FRUIT CULTURE IN VILLA GARDENS.—Mr. G. Bunyard of Maidstone gave an excellent lecture on this subject at the meeting of the National Amateur Gardeners' Association on Tuesday evening last, at the Memorial Hall, Farringdon Street, E.C. There was a fair attendance, and Mr. T. W. Sanders presided. Mr. Bunyard detailed the best methods to adopt, and specially recommended the bush, pyramid, and cordon systems.
- A New Wood.—According to the "Manchester Courier" a new wood has been discovered in Borneo, which promises to supplant oak as a building material. It is familiarly known as "bilian," very close in grain, having a breaking strain greater than that of oak, and with a specific gravity to that of box wood as 3 is to 4, or one-quarter lighter. It is not unlike ebony in appearance, especially after exposure to the air.
- —— AWARDS TO BRITISH EXHIBITORS AT CHICAGO.—We are informed that the Committee of the floricultural section at the World's Fair have made awards to Messrs. John Laing & Sons, for Chinese Primulas; to Messrs. James Carter & Co., for Chinese Primulas, Cyclamens and other flowers; to Messrs. Kelway & Son, for Chinese Primulas (model crimson); to Messrs. H. Cannell & Sons, for Chinese Primulas; to Messrs. Waterer & Sons, for Pæonies and Phloxes; to Messrs. Dickson & Sons, for collections of Azalea mollis and Rhododendrons; and to Miss Margaret Dickson, for collections of Roses. The awards to foreign exhibitors are as follows:—Germany, forty-six; France, twelve; Holland, six; Austria, one; and Italy, one.
- COMPLIMENTARY DINNERS AT EARL'S COURT.—In recognition of his services, a complimentary dinner was given on the evening of the 28th ult. to Mr. H. E. Milner, Chairman of the Executive Committee of the Gardening and Forestry Exhibition. Professor Stewart, President of the Linnean Society, occupied the chair, the company numbering about 100. The Chairman, in proposing the toast of the evening, said they might congratulate Mr. Milner on the success which had attended his efforts to diffuse a knowledge of gardening and forestry, and to foster and encourage those two sciences. By means of this Exhibition employment had not only been given to a large number of persons, but pleasure had been afforded to many thousands. In conclusion, the Chairman presented Mr. Milner with an antique silver bowl as a souvenir of his connection with the Exhibition, which had been subscribed for by a number of personal friends and members of the staff. Mr. Milner, in returning thanks, acknowledged the hearty co-operation of his fellow directors and of the staff, who had worked so hard to make the Exhibition a success. On Monday evening next, the 9th inst., a

dinner will be given to Mr. H. Turner, Vice-President of the Horticultural Department. Tickets can be obtained from Messrs. H. B. Skinner and R. Dean, Secretaries, Earl's Court Exhibition, S.W.

- —— VENIDIUM CALENDULACEUM VAR. MULTIFLORUM.—When I exhibited this plant at the meeting of the Royal Horticultural Society it was not as an object for pot culture, but simply as a much-neglected autumn flowering annual for the open ground that is very valuable at this season of the year. The plant was placed in a pot simply for the convenience of transit to the Drill Hall.—R. DEAN, Ealing, W.
- "For the last three years our bushes of this showy spring flowering shrub have borne fruit, but this year the crop is much heavier. I note Mr. Thomas staged a dish of fruit of it at the last meeting of the Royal Horticultural Society, when a vote of thanks was accorded. Hanging on the trees the fruit is pretty when it assumes the deep yellow characteristic of its ripened state. Is it possible to make any use of the fruit?"
- Tomatoes.—The Rev. J. E. Symns writes from Woodford Wells to the "Times:"—"I am sending some Tomatoes grown under remarkable circumstances. They are quite ripe, and the largest weighs just 9 ozs. The seeds were sclf-sown; they must have fallen from the fruit of last year. When the plants were strong enough they were removed and put in the open ground under a south wall. They were never under glass, nor protected in any way. I shall be glad to learn if there is a similar instance on record in any part of England."
- —— STRAY TOMATOES.—A Bedminster correspondent writes:—
 "Your readers may be interested in knowing that more than a dozen
 Tomato plants may be seen growing in a field leading to Ashton Hill, a
 few score yards from the pond. The plants vary in size, some being
 remarkably vigorous and loaded with fruit; 4 or 5 lbs. having been
 gathered during the past week, consisting of the smooth as well as a
 wrinkled variety. A couple of small plants (though not in flower or
 fruit) may also be seen near the lower gate of the churchyard. Have
 any of your readers observed any similar strays from cultivation
 growing apparently wild in any other locality?"
- GARDENING APPOINTMENTS.—Mr. James Hill, for nearly four years forman at Hopwood Hall, has been appointed head gardener to Sigismund C. de Trafford, Esq., Croston Hall, Preston, Lancashire. We learn that Mr. T. Kent has been appointed gardener to Captain Van Koughnet, R.N.. of Tyttenhanger Park, St. Albans, in succession to his father, Mr. H. Kent, who had forty-three years' service as gardener at Tyttenhanger Park, to the late Dowager Countess of Hardwick, the late Dowager Countess of Caledon, and the present Earl of Caledon.
- THE members of the WARE HORTICULTURAL MUTUAL IM-PROVEMENT SOCIETY on the afternoon of 28th ult. responded to an invitation of their President, Mr. Hanbury of Poles Park, Ware, to visit his gardens and grounds. Seventy of the members attended and spent an enjoyable afternoon inspecting the many noticeable features, and were afterwards regaled to a substantial tea. The gathering was instructive alike to all, as everything is grown in the most creditable manner by Mr. W. M. Alexander the gardener. The improvements made in the gardens of the four or five years by the present owner show considerable taste and add immensely to the beauty of the place. Mr. and Mrs. Hanbury take great interest in the Society, and have invited the members on seven similar occasions.—E. WALLIS.
- EMIGRANTS' INFORMATION OFFICE, 31, Broadway, Westminster, S.W.—The October circulars of the Emigrants' Information Office, and the penny and other handbooks, with maps, show the present prospects of emigration. A new pamphlet on California is also issued. New branch offices have been opened at the public libraries at Peterborough and Swansea. It is too late in the year for emigrants without money—other than female servants—to seek work in Canada, unless they go to join friends. Work in New South Wales, especially in towns, continues to be very scarce. In Victoria good farm hands can get employment throughout the year at about 15s. a week, and all found; but in the towns, and especially in Melbourne, there is no opening for men without capital at the present time. There is an excellent opening in the south of Australia for Vine growers with a little capital. The recent arrivals in New Zealand have been so numerous that there is no pressing demand for more; but the country is so full of resources, and the population is still so small, that anyone arriving there with knowledge of a trade, and with a little money, should do well.

- A Large Pear.—A correspondent writing from Henfield, Sussex, says:—"This week I gathered from a tree on a wall, with an east aspect, in my garden here, a Grosse Calebasse Pear of the following remarkable dimensions and weight. It has at the thick end a circumference of $12\frac{3}{3}$ inches and one of 18 inches lengthways. Its weight is rather more than $1\frac{3}{4}$ lb. There are a few more on the tree, these are very large though not equal to the one to which I refer."
- THE TOTAL RAINFALL AT ABBOT'S LEIGH, HAYWARD'S HEATH, SUSSEX, for the past month was 3.05 inches, being 0.08 inches below the average; 2 inches of this fell during the last week. The heaviest fall was 0.88 inch on the 28th. Rain fell on sixteen days. Total fall for the nine months 16.08 inches, as against 20.27 inches. The average maximum temperature in the shade was 75° on 6th and 14th. Minimum temperature 33° on 24th; mean maximum 66.05°; mean minimum 46.17°; mean temperature 56.11°, being 1.05° above the average.—R. I.
- MICHAELMAS STRAWBERRIES.—As an instance of the remarkable character of the season, a correspondent informs us that a dish of ripe, good-sized Strawberries of excellent flavour were picked this week in the open garden at the residence of the Mayor of Newbury. Strawberries have also been picked in the open garden of the Dundas Arms Hotel, at the neighbouring village of Kintbury, within the last few days. "L. M." writes from Hawkhurst:—"I have just picked a small dish of ripe Strawberries of good size and colour, the first time I ever had a second crop ripen. There are, too, many on the plants nearly ripe."
- The Weather in Hertfordshire. Mr. E. Wallis, The Gardens, Hamels Park, Buntingford, Herts, writes:—The weather during the past month has been of a dry character with an abundance of sunshine. Wasps during the early part of the month were very abundant, doing much damage; but I was never less troubled with caterpillars. Rain fell upon nine days during the month. Maximum in any twenty-four hours was 0.54 on the 1st; minimum in any twenty-four hours was 0.03 on the 16th. Total during the past month was 1.46 against 2.62 of 1892. By the end of September, 1892, I had registered 18.90 of rainfall; end of September, 1893, I have only registered 13.38. In spite of the very dry season garden crops on the whole have done remarkable well.
- DEATH OF MR. FREDERICK LOTHROP AMES .- We regret to learn from the "Garden and Forest" of the death of Mr. Frederick Lothrop Ames, one of the founders and owners of that journal, who recently died suddenly during a journey from his home in Massachusetts to New York. Mr. Ames was one of the most liberal patrons of horticulture America has produced, and his collection of Orchids was a great source of pride to everyone interested in the progress of the art in which he found his principal pleasure. Mr. Ames' love of Nature was real and profound, and his exact and comprehensive knowledge of the plants in which he was particularly interested has given him an international reputation among orchidologists. Through his liberality the Arnold Arboretum, to which he has always given generous support, and the Botanical Department of Harvard College, in which he was specially interested, have been able to extend their usefulness. For nearly thirty years Mr. Ames was an active member of the Massachusetts Horticultural Society; he has long been one of its Vice-Presidents, and as a member of the Finance Committee has rendered it invaluable service.
- A REMARKABLE BOUQUET .- A correspondent at Cork writes : -"The composition of a small nosegay of fresh flowers gathered in County Cork will seem incredible even to those who have watched the progress of this remarkable summer. The bouquet consists of Bramble leaves dyed with the most gorgeous autumn tints-nothing unseasonable in that !-surrounding Apple blossom developed from buds which should have lain dormant until the awakening breath of next spring aroused them. The flowers are as dainty and perfect as the usual spring bloom, but appear strange in their setting of old leaves instead of the soft delicacy of the undeveloped foliage usually attending these precocious blossoms. Then there are wild Roses and buds gathered from a bush which bore similar blossoms on April 26th of the present year, and lastly groups of Strawberry blossom as jaunty and fresh as those of the early summer, and apparently unconscious at present of the rapid approach of cold frosts which have already spread their icy fingers over counties to the north of County Cork. Reports, too, from Killarney and other places tell of Laburnum trees in full bloom, while adjacent are bushes laden with fruits of deepening hues, and close by the Arbutus displays its richest of crimson-red berries."

- VEITCH'S AUTOCRAT PEA. Mr. H. W. Ward writes: "This grand midseason Pea I have grown somewhat largely during the present year with most satisfactory results. It is an excellent grower and prodigious cropper, producing with great freedom large, straight, handsome, dark green, well-filled pods, which contain on an average ten large deep green coloured Peas of excellent quality. I exhibited two dishes of Autocrat Pea early in August last at Southampton and Taunton Shows, which easily secured a first prize. I am still gathering Peas of this variety from sowings which were made the 1st of June. Sowings of Ne Plus Ultra and British Queen were made the same time in the same plot of ground, the rows being 10 feet asunder, running north and south, and heavily mulched on each side, the same as all my rows of Peas and Beans are served, but the yield from Autocrat as well as the quality of the produce is far in advance of that of those two well-tested varieties."
- THE "KEW BULLETIN" for September, a copy of which has come to hand, is wholly devoted to a description of the Flora of St. Vincent and adjacent islets. "St. Vincent is one of the group of islands known in the West Indies as the Colony of the Windward Islands. The other members of this group are St. Lucia, twenty-one miles to the north, and Grenada, sixty-eight miles to the south-west. Barbadoes, under a separate Government, is 100 miles due east. St. Vincent was discovered by Columbus on the 22nd January, 1498. It is situated in 13° 10' north latitude and 60° 57' west longitude. It is eighteen miles in length and eleven in breadth, and contains, according to the Colonial Office List, nearly 85,000 acres of land, about half the area of Middlesex, with only 13,000 acres under permanent cultivation. The population in 1891 was 41,054. The majority of the adjoining islets, known as the Grenadines, are dependencies of St. Vincent."
- From the same source we learn that in the last century St. Vincent was remarkable for possessing the first Botanic Garden (founded 1765), certainly in the West Indies, and perhaps in any tropical part of the world. An account of this garden is given in the "Kew Bulletin" for 1892, pp. 92-100. It lingered on with a precarious existence till the end of the first quarter of the present century. In 1890 it was revived as one of the system of botanical stations established in the West Indies. The scientific knowledge of the flora of St. Vincent was limited to the present time to the species enumerated in Grisebach's "Flora of the British West India Islands" (1864). He relied upon a collection made by the Rev. Landsdown Guilding preserved in the Kew Herbarium. As will be seen the fact that these specimens were in every case actually derived from the island is not free from doubt. Besides these Grisebach also worked up some other plants in the Kew Herbarium collected by Alexander Anderson, the second Superintendent of the old Botanic Garden, of whom some particulars are given in the "Kew Bulletin" for 1892 (pp. 94-5), also by George Caley, one of Anderson's successors (K. B. l. c. p. 97). These data supplied at first a very imperfect idea of the total flora. It was obviously therefore desirable to take advantage of any opportunity for completing the botanical exploration of the island. In 1889 Mr. F. Ducane Godman, F.R.S., to whom the scientific world is indebted for the munificent investigation of the natural history of Central America, determined to send a zoological collector to St. Vincent. Mr. H. H. Smith, a native of the United States, and an expert of known skill and experience, was engaged. He was accompanied by his wife, and Mr. Godman, thinking that they might also do some useful work, for botany, persuaded them after a visit to Kew to undertake the task. On arriving at St. Vincent they ultimately engaged as assistant in botanical collecting, Mr. G. W. Smith (now Curator of the Botanical Garden, Grenada), a native of the Windward Islands.
- The total number of Species of Flowering Plants collected in St. Vincent and the four adjacent islets—Bequia, Cannouan, Mustique, and Union—including naturalised plants and those inserted on the authority of the early collectors is about 1150. Of these Mr. Smith collected 977, whereof at least 131 are almost certainly colonists, leaving 846 indigenous species, belonging to 490 genera and 109 natural orders. The number of species of flowering plants collected in the small islands was respectively:—Bequia, 375; Mustique, 160; Union, 49; and Cannouan, 30. With regard to the general distribution of the indigenous plants, the principal points are the wide geographical range of the majority and the smallness of the endemic element, conditions that obtain throughout the whole chain of islands from Tobago to the Virgin group, which are in striking contrast to the proportions of the endemic element in Cuba and Jamaica.

—— FINE TOMATOES.—I am sending you a box containing some clusters of Tomatoes (Perfection), and shall be glad of your opinion of the same. I gave a note of the culture as carried out here when sending you some individual specimens (vide page 294, October 2nd, 1890), and there it will be seen that the root space for our plants is very limited. I think the clusters now sent, and of which we could gather many, show the value of artificially assisting fertilisation.— Thomas Crosswell, Homewood, Eden Park, Beckenham. [The cluster referred to by our correspondent was very fine, eight highly coloured fruits of perfect form weighing 4 lbs. 4 ozs. On the previous occasion referred to Mr. Crosswell sent us some of the finest Tomatoes we have ever seen, the largest fruit in that case weighing 19 ozs.]

- THE WAKEFIELD PAXTON SOCIETY.—There was an unusually good attendance at the ordinary weekly meeting of the members of the Wakefield Paxton Society on Saturday evening. Lieutenant H. S. Goodyear occupied the chair, and Mr. G. Gill officiated as Vice-Chairman. The essayist was Mr. George Parkin, a well-known photographer, naturalist, and botanist, and one of the oldest, most active, and useful members of the Society. His subject was "Autumn Foliage," and there was a large and beautiful collection of foliage from plants, shrubs, trees, together with a good display of wild fruits and berries. Mr. Parkin read a most interesting paper, which clearly showed that when taking his country rambles he is a close observer of Nature. A discussion was opened by Mr. W. L. Skinner of the Silcoates Nurseries, who was one of the principal exhibitors of specimens. Several of the other members took part in the discussion, including Mr. Mear of the Woolley Park Gardens, who has obtained an appointment on a fruit farm in Australia.

- THE OLDEST TREES IN THE WORLD.—This subject has again cropped up, and is being discussed in "Notes and Queries." The following list of ages known to have been reached by patriarchs of the respective kinds is given by Mr. J. Collinson: - "Elm, 300 years; Ivy, 335 years; Maple, 516 years; Larch, 576 years; Orange, 630 years; Cypress, 800 years; Olive, 800 years; Walnut, 900 years; Oriental Plane, 1000 years; Lime, 1100 years; Spruce, 1200 years; Oak, 1500 years; Cedar, 2000 years; Yew, 3200 years. The way in which the ages of these trees have been ascertained leaves no doubt of its correctness. In some few cases the data has been furnished by historical records and by traditions, but the botanical archæologists have a resource independent of either, and when carefully used infallible. Of all the forms of Nature trees alone disclose their ages candidly and freely. In the stems of trees which have branches and leaves with netted veins-in all exogens, as the botanist would say-the increase takes place by means of an annual deposit of wood, spread in an even layer upon the surface of the preceding one."

- THE JASMINE HARVEST. - Writing from Grasse, a correspondent of a daily contemporary says :-- "The Jasmine harvest here is in full swing. Grasse is permeated by an overwhelming perfume of flowers. In the factories they are working day and night to extract the valuable essence of the flowers as quickly as possible. There are three ways of doing this. The first and coarsest method, which is used for Lavender, Thyme, Peppermint, and Geranium, is by boiling down the flowers. The second, which is used for Roses, Heliotrope, Lilac, and ordinary Violets, is the old plan of distillation. And the third, which is reserved for Parma Violets, Jasmine, Tuberoses, and such expensive essences, is the so-called cold method, the slowest. and therefore the dearest, but the most effective of all. For this last the flowers, which are first carefully weighed, are heaped upon a table round which are seated about twenty girls, each with a frame before her, like a good sized window pane. The glass of this frame is, so to speak, buttered on both sides with a mixture of veal fat and a little oil. On the glass the girl strews as many flowers as will lightly cover it, and covers them with another glass similarly treated. Then comes another layer of flowers and another glass, till there are ten glasses in a heap. The next day the flowers, which are by that time quite faded and have given out all their scent into the grease above them, are removed, and fresh flowers are strewn in their place. This proceeding is repeated eight or ten times. The perfumed grease is then put into large, closed, copper vats, with an equal quantity of spirit. In the vats are wheels which are turned by machinery. The rapid revolutions of the wheels beats out of the grease most of the perfume it has soaked in; the grease sinks to the bottom, and is used to make soap, pomade, &c., and the spirit which contains the true essence of the flowers is bottled, and fetches the highest prices given for scent."

—— PLUMBAGO LARPENTÆ.—What the Gentians are to the embellishment of the rockery in the spring this Plumbago is in the autumn in the matter of colour. It is flowering finely in spite of the dry season we have experienced. No hardy plant that I know gives the same tint of colouring at this time of the year without it be Lithospermum prostratum, and that is not now in bloom, its season having passed. This Plumbago is an easy plant to grow. Any ordinary garden soil seems to suit it, but a freer growth is secured by the addition of a small amount of manure.—E. M.

— Woods and Trees in Scotland.—The Board of Agriculture desire to direct attention to the increased facilities for the planting of woods and trees in Scotland afforded by the Improvement of Land (Scotland) Act, 1893, which received the Royal assent on August 24th last. Hitherto owners of land in Scotland have been able, with the sanction of the Board of Agriculture, to charge their estates for the planting of woods and trees only in cases where the planting is for the purpose of providing shelter. By the Act in question this limitation has been removed, and applications may now be made to the Board for sanction to charge estates, under the provisions of the Improvement of Land Act, 1864, with the cost of planting whether for shelter or otherwise.

ARALIA SIEBOLDI.—Mr. J. G. Pettenger, Strawberry Dale Nursery, Harrogate, writes:—"It is not uncommon to find this beautiful plant grown in the stove or intermediate house, thus subjecting it to attacks of insects or disease, which very soon stops all growth. This plant thrives splendidly in a cold frame, partially shaded from direct sun. The plants are raised in heat in April or May, and after the first potting in 60's are placed in a cold frame. They are in due time shifted into 5-inch pots, in which they make beautiful plants totally different to any that can be grown in heat. In the winter a house from which frost is just excluded suits them admirably. If signs of thrips appear the leaves are sponged with softsoap and warm water. Aralia Sieboldi enjoys liberal supplies of water in well drained pots. The most suitable soil is good sandy loam."

CHINESE BEAN OIL.—More oil is extracted from the bean than from any one of the other oil-yielding plants of China. The two kinds of bean treated for oil are small in size and oval in shape, one having a whitish yellow epidermis and interior, the other being green throughout. They are probably sub-varieties of the Soja bean. The process of extraction in Formosa is described by Mr. Hosie in a recent report on that island. The beans yield about 10 per cent. weight of oil, and the cakes when removed from the press weigh some 64 lbs. and are worth about 2s. 9d. each. They constitute a very valuable manure, and are carefully macerated before being applied to the soil. The commercial value of this industry is shown by the fact that 60,000 tons of bean cakes were exported from Chefoo during 1890, and Newchang sent over 156,000 tons in the same year. The oil is used both for cooking and lighting purposes.

- FORMOSAN TEA.—The cultivation of the Tea, known in trade as Formosa Oolongs, is referred to by Mr. Hosie in his late report on that island. The Tea vant was imported from the Fuhkien province, and proved a great success. Since its introduction the cultivation has spread rapidly, with the clearing of the hillsides in Northern Formosa. When a slope has been cleared of jungle a crop, such as Sweet Potatoes, is planted, and in the following year young Tea plants are set out in rows 2 feet or 3 feet apart, with a like distance between each plant. In this virgin soil no manure is required, and all the cultivator has to do is to keep the ground clear of weeds and undergrowth. In three years from the date of planting out the shrubs have attained their maximum height of 2 feet to 3 feet, and the time has arrived for picking the leaves. This operation, which is carried out by women and girls for the most part, takes place in the end of April or beginning of May, in July, and in September, for three crops are harvested during the season. The Tea manufactured in Formosa is generally, but erroneously, classed as a green Tea. It is in reality a black Tea, prepared without the usual fermentation, but it possesses a decided flavour of the green variety. The leaf is "fired" when green, and this, taken with the flavour, may account for the popular belief. But between the exposure in the open air and the firing the edges of the leaves are rendered quite soft by being thrown against Bamboos in a revolving machine - a process unknown elsewhere in China. It is said that if the leaves, after being picked and exposed for a short time, were placed in the firing pans they would split up—the Tea leaf is thick and brittle—and lose all semblance to the whole leaf which is so much desired.

CAUSES OF SHANKING IN GRAPES.

In addition to the various theories propounded by your correspondents (page 262) as to the causes of shanking in Grapes, I will venture to add another one, and that the application of too much water, especially if the Vines should be rooting in a retentive soil. This I proved to my own satisfaction some years ago, although it may not concur with the experience of those advocates who advise the application of water to growing Vines in unlimited quantities at weekly or bi-weekly intervals. According to these practitioners it is impossible to overwater Vines, irrespective of the size of the border or the nature of the soil they are rooting in, and is supposed to be the panacea for recuperating their energies if any ill should befall them. There are, however, many cases where not nearly sufficient water is given.

Some time ago I was, like many other gardeners, imbued with the idea that there was nothing like plenty of water for Vines if Grapes of the highest quality were desired, and of this element the borders had a surfeit, and the Vines, too, as I had about as bad an attack of shanking to contend with as there could possibly be. Upon examining the border it seemed cold and inert, with the ends of the young roots decaying away. This was a lesson to me that I shall ever remember. The roots were completely paralysed, consequently they were quite unable to afford adequate support to the Vines at a critical period. Since that time I have always been more sparing in the application of water, never

applying it until the border was in condition to receive it. When to apply water depends upon the size and also formation of the rooting

medium.

I do not dispute in the least the causes propounded on the page mentioned, as if good Grapes are to be secured all are shoals, of which everyone should steer clear. The benefit of a covering of warm leaves as explained by Mr. Ward I can fully endorse, as the beneficial properties of which for forced Vines I have proved repeatedly. This, as many readers are aware, is no new idea, but an old method. There is one error, however, that many cultivators who adopt the practice often fall into, and this of removing the covering too early. Probably a suitable warm covering was placed on the border at the commencement of forcing, this period being either December, January, or even well into February, and kept up till the weather becomes warmer. At this time the covering is removed, and the Grapes are at a critical stage, the colouring process only commencing. This sudden removal of the material undoubtedly gives the Vines a check, the roots becoming quite disorganised, with the result of colouring being arrested and also an attack of shanking. This past season, although the weather was fine and warm, I did not remove the covering from our early Vine border until the Grapes were almost perfectly coloured, and looking back over a series of years I never had early Grapes better or more free of shanking. The Vines are very old, with rods and spurs of an antiquated appearance. Covering with cold manure or exposed to the weather after being put on is of little benefit, as if open to rains and snow the material soon loses heat and becomes a cold inert mass, making the border cold also, consequently it is impossible for the roots to remain active. After placing on a layer of leaves the whole should be covered with properly constructed boards or sheets of corrugated zinc.

The benefit which accrues to Vines from lifting the roots out of deep

and cold borders, and relaying them nearer the surface in suitable compost, is only too well known to those gardeners who have adopted the practice. It is a never failing remedy of rejuvenating the most decrepit of Vines, and where shanking is due, or can be traced to the Vines rooting deeply in a cold and inert soil, this process, with other cultural details well attended to, will arrest it completely.—A. Young.

SHANKING may be caused by overcropping, neglect in growth, tops running wild, and then shortened back wholesale. It is also caused by the Vines growing in an imperfect border, combined with bad drainage. All Grapes have a tendency to thus shank more or less. Shanking in a green state is no doubt caused by defective root-action, the top growth being in advance of roots. Possibly it is caused by the loss of fibrous roots during the winter. In this case it plainly shows a weakness, and can be remedied for the next season by draining and renovating the

border, top-dressing, and applying less water.

Whatever may be said to the contrary, I have proved that chemical manures are far in advance of that from the farmyard. True, the immediate gross growth does not follow the application of chemicals, but, on the other hand, we have sounder fruit of higher flavour, with hard close grained wood for our next season's crop. Vines that are over-cropped are most liable to shanking, though it may also be caused by want of water at the roots in hot dry weather, combined with a low temperature at night or early mornings. In Gros Colman it is a shoulder that is generally affected. This can be removed without any great detriment to the bunch beyond the actual loss of weight. Black Alicante will go at the bottom, the first symptoms being slow colouring. Lady Downe's is often affected on the top where we can least spare berries. Cold sour borders will also produce this disease, but growers can by careful attention reduce it to a minimum. Some persons profess not to have shanking, yet I question if any vinery is faultless for one year.

Should shanking arise from any accidental cause, as overcropping or neglect of attention in the due stopping of the growths in proper season, this will not necessarily follow the following year if attended to. If, however, the fault be at the roots or border it will be more difficult to cope with. In wet sunless seasons with outside borders shanking is generally prevalent. The remedy will be in lifting the Vines or protecting the borders. No doubt there is a form of shanking that arises from unripened wood of the previous year. Damage to the roots will also cause shanking. Some four years since I had several Vines, the roots of which were mutilated by moles, the result being red sour berries. Now they are not quite perfect, but improve every year .- STEPHEN

NEPENTHES MIXTA.

THIS Nepenthes, which is depicted in the accompanying illustration (fig. 45), is an interesting and highly coloured hybrid, being the result

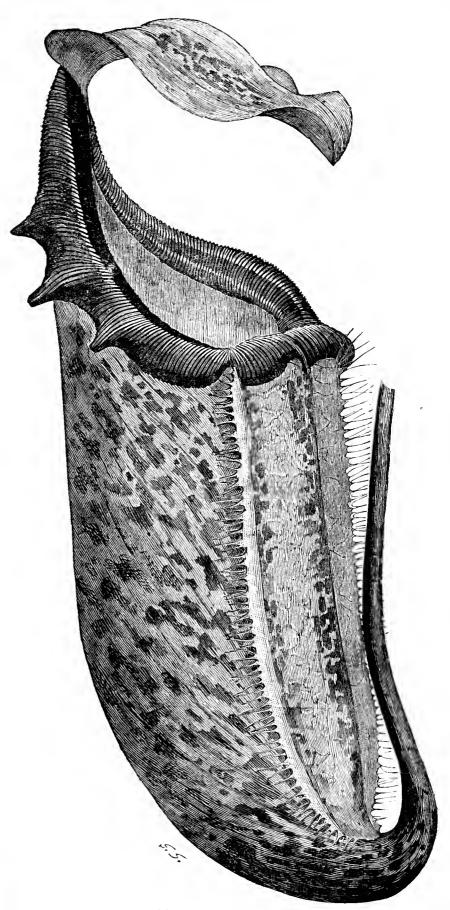

FIG. 45.-NEPENTHES MIXTA.

of a cross between N. Curtisi and N. Northiana. It was raised by Messrs. J. Veitch & Sons, Chelsea, and was exhibited by them at the Drill Hall, James Street, S.W., on Tuesday, September 26th, when the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for it. The pitchers are about 9 or 10 inches in length, somewhat narrow, of a greenish red heavily blotched with brownish red. The ribs which surround the mouth of the pitcher are dark crimson, which enhances its appearance. The plant shown on the oecasion mentioned bore six fine pitchers.

NATIONAL CHRYSANTHEMUM SOCIETY.

AT the Floral Committee meeting held at the Aquarium on the 27th ult. the following varieties were awarded first-class certificates.

Gustave Grunerwald.—An early flowering decorative Japanese of a light mauve colour passing to white. Exhibited by Mr. N. Davis.

Mrs. C. B. Myers.—A large exhibition Japanese, solid and well

Mrs. C. B. Myers.—A large exhibition Japanese, solid and well built, colour white shaded yellow. Sent by Mr. R. Owen of Maidenhead.

President Borrel.—A variety with long petals of the Japanese type, with a striking purple colour and golden reverse. A massive flower, staged by Mr. Rowbottom.

MADAME DESGRANGES CHRYSANTHEMUM.

THE well-known Chrysanthemum Madame Desgranges and its yellow sports are valuable for decorative purposes, and are somewhat extensively cultivated. To grow these Chrysanthemums into good bushes strong cuttings should be secured about the middle of October, preference being given to those springing from the roots, and place them singly into small thumb pots, using loam, leaf mould, and sand in equal parts. Plunge them in a half-spent hotbed, and keep them close until rooted, only admitting sufficient air to dispel superabundant moisture, and thus prevent damping. When rooted they should have abundance of ventilation during favourable weather, and keep them near to the glass, so as to induce a short-jointed stocky growth, nothing being so detrimental to Chrysanthemums as "coddling" at any stage. Grown under airy, bracing conditions, they will bear a few degrees of frost without injury, and although the growth will be slower, yet in the spring the plants will possess far more stamina than those grown under close, warm conditions, and may, moreover, be placed out of doors a month earlier in spring.

When the plants are 6 inches high, pinch off 2 inches of growth; this will induce them to throw out a number of side shoots. Select three of the strongest, and rub off all the others. At this stage, which will be the end of November, they will require placing into 5-inch pots, using a compost of three parts fibry loam and one part each of well decayed manure, leaf mould, and sand, adding 1 quart of bonemeal and soot to each bushel of compost. They should be potted firmly and returned to a cold frame with a south aspect if possible, and as the days are short and damp they will not require keeping close, neither will they need watering for at least a fortnight, and every opportunity should be taken to give air, and on mild days to remove the lights entirely. During very severe weather the lights may be covered in the usual way, but a little frost will not hurt the plants. Damp, however, must be expected during the dull days of winter, but this can be largely obviated by making a wooden slatted stage for the frame, and arranging the plants on it near to the glass, giving them plenty of room. Watering also should be attended to during the early part of the day. Early in February the shoots should again be pinched back and two growths selected which will give six shoots to each plant. Early in March place the plants into their largest pots, using those 8 and 9 inches in diameter.—SPECIALIST.

A GLANCE AT SCOTTISH GARDENS: DALKEITH.

My initial visit to Scotland took place a week or two since, and as I chose Edinburgh as my headquarters I saw much to interest me in as well as outside the city. My first visit was made to Dalkeith, and a most enjoyable and at the same time instructive one it proved. I was unfortunate enough to find Mr. Dunn, the well-known gardener, on the sick list, and unable to leave his house, which latter fact I believe caused him more worry than all the pain, as he is, as many people know, one of the most energetic of men. He did, however, everything he could for me by deputing one of his foremen to show me round the gardens. What struck me particularly at this, as well as at the other places I visited, was the exceptional cleanliness which pervaded the whole—houses, flower, kitchen, and fruit gardens were alike in that respect. This was I think more noticeable here than in many English gardens that I have seen, where the minor details seem to be ignored. In so doing a great mistake is made, for not only is the appearance of a garden much enhanced by this freedom from weeds, but the crops that are planted thrive best on clean, sweet ground. Almost all the fruit from the trees indoors had been gathered, but I was informed there had been very fine crops. A few Grapes were still hanging, and taking those as a criterion the bunches must have been exceptionally fine. Bananas are finely grown, and several splendid clusters of the luscious fruits were to be seen in various stages of ripeness. Monstera deliciosa was also carrying numbers of fruits.

Out of doors, however, there was still a wealth of bloom and an abundance of hardy fruits. Apples have been exceptionally abundant, as also have Pears, and the trees here, as well as those indoors, bear the

impress of excellent management. Signs of the drought which has played such havoc in many gardens throughout the kingdom this year were noticeable. The Plums were practically all gone at what is in ordinary seasons the height of their perfection. Amongst the flowers Dahlias were very prominent and remarkably beautiful, most all of the various types being strongly represented. The Stocks were a wealth of bloom, pure white and red, and of delightful fragrance. They grow well at Dalkeith, and evidently they are highly appreciated, for there seems to be an almost endless supply of them. But how useful they are for cutting! They afford innumerable flowers, which stand well in water, and the perfume is, I believe, almost universally liked. Sunflowers reared their gigantic heads here and there in the borders, whilst the Lobelias in all their dwarf beauty formed the groundwork of some charming beds. Zinnias, too, were noticed in great numbers, providing a diversity of colouration which entitles them to more general cultivation. Their culture is of the simplest, and their beauty cannot be questioned. A walk across the park brought us to the place where the gardens were in bygone days, and of which but one relic remains in the shape of a large stone-built conservatory of much beauty filled with Palms and other plants which have grown too large for the accommodation which the structures in the gardens afford. There were numberless other things seen, but I must leave the good work at Dalkeith and allude to other gardens.

NEWBATTLE ABBEY.

This, the seat of the Marquis of Lothian, is renowed in history, and though there remains little of the old Abbey, yet its style of architecture remains unaltered, as the additions which have been have followed closely the ancient pile. The grounds here are under the charge of Mr. Macdonald, who, though but a short while there, has made his presence and personality felt in the gardens, which are in an excellent condition. Chrysanthemums are a great feature, some hundreds of plants being grown, and if appearances deceive not, will afford some grand blooms. They are clothed almost to the pots with foliage of a rich dark green colour and of exceptional substance. Truly they are splendid plants. The flower garden was bright with brilliant hued Pelargoniums and Calceolarias, between them being turf, better than which one seldom sees. No signs are displayed of dry weather, everything betokens good culture, which signifies nothing less than unremitting and untiring attention. A proof of the exceptional season—if proof is required—is found here in a large Rhododendron which has made a second growth, and was, at the time of my visit, carrying an abundance of medium-sized trusses of well-coloured perfectly developed blooms.

Indoors neatness prevails. "A place for everything, and everything in its place," appears to be one of Mr. Macdonald's mottoes. The collection of Masdevallias is a justly celebrated one, and contains every known species and variety of merit. Unfortunately for me I had come at the wrong time to see them in flower, but one can readily imagine that when at the summit of their beauty they present a spectacle which could not fail to gladden the eyes, and mayhap the heart, of everyone, whether he be an orchidist or not. They would assuredly be worth going many miles to see. These Masdevallias are, I understand, the pet hobby of the Marquis, who is at present engaged upon an exhaustive work on this genus. Another plant worthy of special mention is a grand specimen of Bougainvillea glabra trained to the roof of a cool greenhouse, a position which is evidently well suited to it, as it is carrying an enormous number of flowers. This is a plant often found in a stove, but such a high temperature is evidently not an essential to success in its culture, for a finer plant could not be wished for than that at Newbattle. There is here, too, a delightful fernery, where Adiantums, Pterises, Aspleniums, and numerous other Ferns grow and thrive to perfection. Huge boulders have been procured, with the idea of carrying the fernery underground, to come out into the gardens by a flight of steps of a gentle incline. This project if carried out, and good Ferns planted therein, would greatly enhance the charms of a home which is already beautiful, and would be such a place as Mr. Schneider, of Messrs. Veitch & Sons', would revel in.

I cannot leave Newbattle without a word in praise of the fruit. Peaches and Nectarines had all gone, but Grapes indoors, and Pears and Apples out, were magnificent, and a great credit to the gardener. There were some grand bunches of Black Hamburgh hanging on the Vines, the berries of which were perfectly finished in every way. Many other varieties are grown of course, but these remarks may safely be applied to them.

MELVILLE CASTLE.

Still following Mr. Dunn's advice, I next walked to Melville, one of the homes of Lord Melville, and here, standing out pre-eminently above everything else, is a long border devoted to herbaceous plants. Bushels of blooms might be cut and not one missed, they are so plentiful. To select one plant from the whole as the most beautiful may appear presumptuous; nevertheless, for profusion of flowers, good effect, and general utility, I should certainly give the palm to Anemone japonica alba. I do not remember ever seeing finer clumps. Michaelmas Daisies, too, made a brave show, many varieties being grown. Second only to the Anemones in floriferousness were the Phloxes, these forming a most brilliant feature. Dahlias were also very attractive, the Cactus varieties being particularly showy. Other plants were there in endless numbers, but those I have named must suffice. Dotted here and there in the borders, and forming in places large masses, were some plants of scarlet Verbenas which looked very beautiful, and though said to be shy growers in some places, are certainly worth a trial

where such has not already been given them, for where the plants grow

well they are admired and appreciated by nearly everyone.

The glass houses are not very extensive, and are devoted principally to fruit, Grapes being a good feature. Some large bunches were noticed of the renowned Raisin de Calabre used mainly for decorative purposes. Black Hamburghs were well represented, the berries being very fine. In the structures devoted to plants, Ferns were exceptionally good, as also were Palms and Crotons.

The kitchen and fruit gardens both looked well, the latter having been very heavily cropped. Apple trees were in a few cases blooming for the second time, and this after carrying exceptionally fine crops of fruit. Mr. Mackinnon is to be congratulated on the excellent state of

the gardens which he has under his control.

TYNNINGHAME.

There are many things worthy of mention at this, one of the residences of the Earl of Haddington. The gardens are and have been for many years past in the charge of Mr. R. P. Brotherston, well known as an excellent gardener, and as a contributor to the Journal of Horticulture. The gardens are a credit to any gardener, and though the glass structures have mostly seen their best days they yet contain some fine plants and fruit. Plants are very largely grown for affording cut flowers here, and foremost amongst these come the Carnations, of which a very choice collection has been brought together. Souvenir de la Malmaison in various shades are grown in large numbers, and appear to be in the best of health, though showing, owing doubtless to the extraordinary season, a tendency to premature flowering, which may detract somewhat from the value of the plants next season. The beautiful Germania is also extensively cultivated, many hundreds of layers having been rooted this year. Sweet Peas, too, are a great feature, most of Mr. Eckford's best varieties being grown. Amongst these are some very beautiful colours, one of the best being Countess of Radnor. Affording as they do an abundance of flowers these Sweet Peas must be invaluable. The Blue Pea (Lathyrus sativus) is also grown, and a small clump of it is a very beautiful sight, and is moreover useful for decorative purposes. Mignonette thrives admirably, producing huge spikes of its deliciously scented blossoms, the variety Machet being perhaps the largest.

The flower garden is furnished with Zonal Pelargoniums, Calceolarias, Tritoma Uvaria, and other plants, and was looking very gay when I was there. The crop of Apples has been a wonderfully heavy one, as also has there. The crop of Apples has been a wonderfully heavy one, as also has the Pears, many of both having been gathered and yet leaving bushels on the trees. Pears on the walls were looking grand, many of the very best varieties being planted, notably Clapp's Favourite, Souvenir du Congrès, Williams' Bon Chrêtien, and Louise Bonne of Jersey. Plums too were hanging here and there, but the majority had of course been gathered. Indoors the Vines were looking splendidly, and some very serviceable bunches were hanging. Tomatoes too were fine. The plants indoors were in excellent health, and Crotons especially were very highly coloured. Ferns are grown in large numbers, and some highly creditable specimens were noticed. On the shore of the Firth of Forth, upon which the estate is situated, the Sea Buckthorn was looking beautiful and carrying a huge crop of its brightly coloured berries. There were many other plants and fruits worthy of note, but I must leave those to be dealt with by others at some future time. A visit to Tynninghame will be conducive to thorough enjoyment, and much valuable information may be gained in walking through the gardens with Mr. Brotherston.—NOMAD.

EXPERIENCE WITH APPLES.

AT the time when the characteristics of Apples and the value of the crops can be best judged, a few notes from cultivators would be opportune and instructive. I send three which may perhaps lead to others from cultivators in different parts of the country.

WEALTHY.

In your report of the discussion that took place at the last meeting of the R.H.S. Fruit Committee, I notice that some members expressed their strong disapproval of the growth and bearing habit of this Apple. With me the growth is moderately strong, with a slight symptom of canker showing on one or two shoots of last year's growth. There is, however, nothing to give cause for alarm in that respect, as the cold, heavy soil here is certain to develop canker if the variety is addicted to it in any way. The tree from which the fruit was gathered was a maiden in 1891, and this year bore eight Apples, all equal to those before the Committee. Many were removed by thinning when quite small to give size to those retained. One of the Apples measured 12 inches round. In the Journal of September 21st I note it is being largely grown at Denver, an Apple-growing district in America. Here Wealthy is thought highly of; so much that I hope to increase our stock very considerably in the coming planting season.

ECKLINVILLE.

No Apple that I know will grow better and give a larger return of fruit in a short time than this, but what is the use of the quantity if there is difficulty in disposing of the produce? As is well known this is a "soft" Apple, easily bruised, and fruiterers with whom I have done business refuse to buy Ecklinville at any price. If this is the case in one town, is it not likely to be the same in others? How, then, is it possible to dispose of the fruit? Much as I appreciate this Apple for

its growth, cropping, and cooking qualities, I am compelled to warn others of the risk they run in planting it extensively.

DUCHESS OF OLDENBURG.

Anyone requiring a good early cooking Apple to be grown as an espalier could not do much better than plant this Russian Apple. The finest crop I have seen of it was produced by an espalier-trained tree in the garden at Hill Place, near Bishop's Waltham. The fruit was packed as close as it could be on all the branches, was of large size and magnificently coloured. I was much impressed with the variety after seeing it so successfully grown.—E. MOLYNEUX.

PEASGOOD'S NONESUCH.

This Apple has done well in the neighbourhood of Bristol. TWe recently saw fruit grown in the gardens of Cote House (Mr. Bannister, gardener), on a bush tree, one fruit weighing 1 lb. 12 ozs.; two weighing $3 \text{ lbs. } 7\frac{3}{4} \text{ ozs.}$; six weighing 8 lbs. $13\frac{1}{2} \text{ ozs.}$; twelve weighing 15 lbs. 13 ozs.-Jas. Garaway & Co.

DEATH OF MR. G. BOGUE.

MANY readers of the Journal of Horticulture, as well as ourselves, will hear with deep regret of the death of Mr. George Bogue, of 10, Hill Street, St. Albans, which took place just before midnight on Tuesday, September 19th. The deceased, who reached his eighty-sixth birthday only on the previous Wednesday, was familiarly known throughout the city, owing to his long connection with it. He had been in failing health for some time, yet he was out a fortnight before his death. It was then that he took a cold, and it seemed doubtful if he would recover, his constitution having been impaired by a serious illness in the spring. Mr. Bogue was a native of Lanarkshire, and came to St. Albans as head gardener to the Earl of Verulam, at Gorhambury, about forty-six years ago, and remained in his Lordship's service for twenty-eight years.

Many years ago Mr. Bogue used frequently to contribute articles to this Journal, which were of a sound practical character. Mr. Bogue also for many years supplied annually to the "Herts Advertiser" a rainfall table. As showing the interest Mr. Bogue always took in this kind of work, it might be mentioned that only a few weeks back, when showing the apparatus to a friend, he expressed his wish to have it fitted up, and thought he should begin again. The deceased, during his connection with Gorhambury, was a member of the Committee of the Royal Horticultural Society, and seldom failed to attend the meetings in London, and in the last few years of his life the deceased often referred with pride to this, and would speak in glowing terms of the times when he had set at a Committee meeting with the last few times when he had sat at a Committee meeting with the late Prince Consort. During the last eighteen years Mr. Bogue had lived a life of retirement, and filled the office of churchwarden at Christ Church for a long period. He, however, gave up his position some five years ago owing to increasing age, and on that occasion he was presented with a valuable inkstand as a mark of the esteem in which he was held. There are only a few distant relatives of the deceased in England at the present time, most of his nearer relations having emigrated and attained to very good positions abroad. The funeral took place in the St. Michael's Churchyard, St. Albans, on Saturday afternoon, September 23rd. (St. Michael's Church is within the precincts of the ancient Roman city of Verulam, and contains a fine marble monument of the famous Lord Bacon). The service was conducted by the Rev. W. Horne, and among those who followed to pay a last tribute of respect to the deceased were Miss Henley and Miss Allard (sisters-inlaw), Mr. Horsfield (steward to Earl Cowper), who is a nephew of the deceased's late wife; Mr. Garner, Mr. J. Child, Mr. W. Dunham, Mr. W. Bowes, and Mr. Whitelaw (gardener to Lord Grimthorpe at Batch-

The "Herts Advertiser," from which the foregoing record was mainly taken, did not reach us till after the publication of our last issue. It was while our late contributor, coadjutor, and friend, who has passed away so full of years and honour, was gardener at Gorhambury that articles from his pen appeared in the Cottage Gardener and Journal of Horticulture. These were stamped by the teachings of experience, and

were proof of cultural attainments of a high order.

SOFT VERSUS HARD COLD WATER.

My first remarks upon this subject may, I admit, be open to misconstruction, but were certainly not written with the object of implying "W. P. W." had betrayed confidence in any way, the reverse being the case. I hope in future to strictly avoid touching the very sensitive feelings which "W. P. W." appears to possess, and will now content myself by taking a careful survey of the articles written, and endeavour to explain a few facts, prove a few statements, and accept without hesitation the challenge thrown out by "J. B. R." (page 286), therefore I can only touch lightly upon the first-mentioned correspondent's article to save repetition. The "subtle shaft" which "W. P. W." has hurled with such mighty force falls harmless to the ground, and leaves me still free to concentrate time and attention to "J. B. R.'s" article, in which he distinctly implies that I wish to turn the matter into other channels. This is decidedly wrong; my conviction strengthens rather than diminishes. I have no intention to "play upon words" this communication, my duty being to accept the challenge to quote an authority where "hard cold water" is described in words equal to

"obnoxious drug."

First, What is the meaning of "obnoxious?" Anything in disfavour; and I take that "hard cold water" is distinctly in disfavour with me; "drug," anything used which proves hurtful to the constitution of animals or vegetation. This is my explanation of "obnoxious drug." Now turn to "slow poison," and the meaning reads, anything which is injurious to life, animal or vegetable. Will this explanation satisfy your correspondent? The first authority I quote is "Johnson's Gardeners' Dictionary" (page 818), which reads, "That known as hard water, containing an express of salts of lime or means is invariably prejudicial." taining an excess of salts of lime or magnesia, is invariably prejudicial," in other words injurious. To subject the roots to an excess of this element which "hard cold water" contains, acts as a "poison" instead of a nutriment to the plants. In support of this statement allow me to point "J. B. R." to the experiments recorded in "Thompson's Gardeners' Assistant" (page 57), it will then be for him to prove my statements are "grossly incorrect."

I will advance another step and quote the experience of men whose authority is recognised throughout the gardening world. First, we read in that valuable work the "Fruit Growers' Guide," by J. Wright (page 291), "Water should never be less in temperature than the mean temperature of the house, and it is better if 5° warmer." Now turn to "Fruit Culture," by J. Cheal (page 128) and read, "Be careful not to use cold spring water or the chill will be too great." Would these warnings, I ask, be necessary if "hard cold water" was beneficial? No! they distinctly point out that it is the reverse of beneficial. "Hard cold water," I repeat, prevents heat being carried down to the roots, and when these are chilled they cannot produce healthy vegetation. Knowing this what possible deduction can be drawn from "J. B. R.'s" assurance that "hard cold water" is highly beneficial to vegetation? He commits himself to "dicta," and it is for him to prove that our practical and scientific authorities are wrong. Allow me to return the challenge and ask "J. B. R." to quote an authority outside this discussion where "hard cold water" is described as highly beneficial

to vegetation.

I was surprised to see Mr. Molyneux's communication (page 286) in which he states that "hard cold water" has a distinctly nourishing effect upon Chrysanthemums and other plants, for in his book on "Chrysanthemums and their Culture" (pages 54 and 55) we find, "Where water comes direct from wells or water companies' pipes in a cold state means should be taken to expose it to the sun's rays and air some time previous to using." Now that his ideas have advanced in such a remarkable manner, he ought, in all fairness, to rectify the statement in his book, because advice which is bought ought to be of the best and not subject in any way to contradiction by the same author in other channels.—F. DUNN.

MADAME PATTI'S LOVE OF FLOWERS.

MADAME ADELINA PATTI has contributed a characteristic "Page of Confessions" to a London magazine. In answer to the question, "What flowers do you most admire?" she replies, as I think very sincerely, "I love them all." Nevertheless, like most amateur horticalturists, the prima donna has her special favourites. She said to me some years ago, during the interval at one of her memorable Irish concerts, "If ever you wish me to wear any special flowers when I am singing do not send me Lilies, whose fragrance is so powerful as to have a sickening influence; I would infinitely prefer either Roses or Carnations. I, however, admire greatly the Lilies which you send to me, and though for this special reason I cannot wear them I have them beside me here." I observe on page 292 it is predicted in an interesting article that Lilium Henryi will soon become a favourite with the ladies. Another Lily which might safely be worn by them is L. speciosum Kraetzeri, the fragrance of which is much more delicate that that of L. auratum or L. longistorum.

Madame Adelina Patti is not only a lover, but also a great cultivator of flowers, and her famous conservatories at Craig-y-Nos Castle, in which grow luxuriantly the rarest exotics, are among the finest in the kingdom. All of these are lighted throughout with electricity, and present, when thus illuminated in the evening, a fascinating scene, especially when the subdued radiance from the electric lamps, falling on the river Tawe, transfigures the rushing waters of that mountain stream.—David R. Williamson.

LONDON TREES.

It is quite true, as stated in "The Times" of the 20th ult., and reproduced in the Journal of Horticulture, page 295, that the flowers of the Ailantus have an unpleasant smell. But this, in my judgment, does not militate against its value as a London tree. The scent is scarcely perceptible in the open air in England, and the flowers pass quickly away. The huge tree in my garden is nearly 50 feet high close to the house, so close that the extreme branches overlap the windows. An average of twelve persons, exclusive of visitors, has lived in the house for more than twenty years, and during the whole of that period I have heard but one allusion made to the scent of the flowers. A grove of it might prove objectionable, but there is no fear of annoyance from a short line or lines of trees. I have often admired this tree in the streets in France, notably in the west, and recently saw an advertisement for trees in a German periodical. Flowering in the hottest time

of New York it may be objectionable there, probably is so; of this I have had no experience.—WM. PAUL, F.L.S.

THE following correspondence also appeared in "The Times" insupport of Mr. Paul's contention:—"The scent from the Ailantus tree flowers is quite innocuous and by no means powerful. Just outside the windows of the Palace at Wells may be seen the finest specimen in England, and as his Lordship daily takes a walk beneath its shade, and as he is in his eighty-sixth year, obviously he has not suffered from the proximity of his giant neighbour." Another writer says:—"Referring to recent Another writer says :- "Referring to recent correspondence on this subject in your paper, I may mention there are three varieties of the Ailantus, or Tree of Heaven. Two of these bear evil smelling flowers, while the scent of the third is, as Mr. Paul describes it, scarcely perceptible."

THE "MARTIN" FLOWER RACK.

THE accompanying illustrations represent the "Martin" Flower Rack, a sample of which has been sent us by Messrs. Corry & Co. (Limited), 13, 15, and 16, Finsbury Street, London, E.C. This useful contrivance was invented by Mr. J. Martin, of Messrs. Sutton & Sons, Reading, and it will doubtless prove valuable for exhibiting cut flowers, also for arranging blooms in vases or glasses. The rack depicted in the small sketch can be easily filled with flowers before placing it in the vase, as shown in the larger engraving. It can also be utilised, if

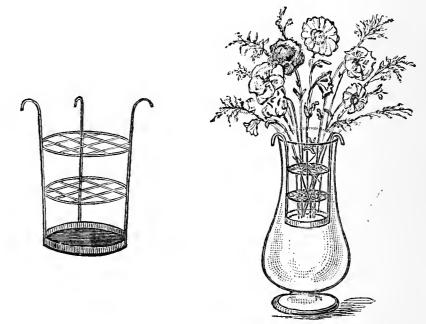

FIG. 46,-THE "MARTIN" FLOWER RACK.

suspended by wire, for displaying dried flowers and grasses, the sides of the rack being covered with green moss. The rack is made in various sizes, from $1\frac{1}{4}$ to $2\frac{1}{2}$ inches in diameter.

THE ROSELANDS, SOUTHAMPTON.

DURING a recent holiday I took the opportunity of visiting the flourishing seaport town of Southampton, and after viewing the new pier and docks I went across the ferry to the pleasant village of Woolston, with the intention of seeing the grounds and conservatories at The Roselands, the seat of W. Garton, Esq.

Mr. F. Jennings, the head gardener, welcomed me, and by him I was shown a fine range of Peach houses. The trees at the time of my visit were carrying a splendid crop of fruit. Some of the trees were moved last year, but they are making fine wood for next season. We next entered the early vinery, in which the Vines are being prepared for forcing. Near the last named structure is a fine span house, filled with Maréchal Niel Roses. In the next house a grand crop of Tomatoes was noticeable. The frames are now filled with Bouvardias, Primulas, Cinerarias, Freesias, and Zonal Pelargoniums. About 1000 Chrysanthemums are grown on the cut-back system. The plants are dwarf, and the foliage is good. We next visited the conservatory, which is a very long span-roofed structure, filled with choice plants. From thence we entered the large fernery, which was designed by Mr. Jennings. There are two fine specimen Palms in the centre, and a host of other plants, that deserve more than a passing reference. A house filled with Crotons, possessing well coloured foliage, is especially interesting. The conservatory, fernery, and Croton house are lit by the electric light, which at night add considerably to their attractions. A large stove, containing the fine specimen plants which Mr. Jennings has exhibited at Southampton the last two seasons, also forms a feature at The Roselands, as does the propagating house, where hundreds of seedling Palms and young

Crotons are grown for decorative purposes.

Besides the early house mentioned, there is a fine range of vineries, containing well finished Lady Downe's, Black Alicante, and Muscats. We next passed through a long archway covered with Pears and climbing plants, the whole presenting an attractive appearance. The lawn is well kept, and the carpet bedding and an avenue of half-standard Acacias were most noticeable. The same may be said of a fine tennis court and bowling green. The grounds are not extensive, but afford many beautiful views, and being well kept reflect much credit upon Mr. Jennings.—A GARDENER.

COUNTY OF GLOUCESTER AND CHELTENHAM ROYAL HORTICULTURAL SOCIETY'S SHOW.—SEPT. 27TH, 28TH.

THE annual autumn Exhibition of this Society was held in the Winter Gardens, which is admirably adapted for the purpose, being a fine, spacious, well lighted, and central building, on the above dates. Taken altogether the Show was a good one. In the plant and cut flower classes there was a falling off both in quantity and quality, but the fruit section was a decided advance, some remarkably fine exhibits being staged. Vegetables were very good for the season.

cut flower classes there was a falling off both in quantity and quality, but the fruit section was a decided advance, some remarkably fine exhibits being staged. Vegetables were very good for the season.

For six stove and greenhouse plants Mr. J. Cypher, Cheltenham, secured, as usual, first honours with large well-bloomed plants, the best being Ixora Pilgrimi and I. Williamsi. Messrs. Heath & Son, Cheltenham, came second with some excellent plants. With thirty plants, in or out of bloom, grouped for effect, Mr. J. Cypher and Messrs. Heath and Son took the honours as named, both staging gigantic plants in prime health and condition. For twenty-four Dahlia blooms, distinct, Mr. Thos. Hobbs, Bristol, was first, Messrs. Heath & Son a very close second, and Mr. Humphries, Chippenham, third. With twelve Dahlia blooms, distinct, Mr. Hobbs was again first, Mr. T. Haskins, Bristol, second. For twenty-four German Aster blooms Messrs. John Price & Son, Stonehouse, were first. Mr. G. Garraway, Bath, occupied a similar position for twenty-four French Asters. For thirty-six Rose blooms Messrs. T. J. Townsend & Son were first, Messrs. Perkins & Son, Coventry, being second. Messrs. Perkins & Son were an easy first for the best bouquet, made up in their usual faultless style. Mr. J. Cypher was first for twelve varieties of herbaceous flowers, Messrs. Heath & Son second. The same exhibitors were placed as named for twelve exotic Ferns, both staging massive well grown plants.

staging massive well grown plants.

For six bunches of black Grapes in two varieties, the Rev. G. Coventry was first, Gros Colman and Gros Maroc very fine; Canon Coventry, Severn, Stoke, second, with fine bunches of Gros Colman and Alicante. For three bunches of black Grapes, Mr. George E. Cox was first; Lieut.-Colonel Rogers second, both showing well finished Alicante. With six Colonel Rogers second, both showing well finished Alicante. bunches of white Grapes, two varieties, Mr. D. Sheppard was first with Bowood Muscat and Muscat of Alexandria; Rev. G. Coventry second. For one dish of white Grapes Mr. G. E. Cox was first, Canon Coventry second, both staging Muscats. For two bunches of black Grapes the Rev. G. Coventry was first and C. Lee Campbell, Esq., was second, both putting up fine, well coloured bunches. With eight dishes of fruit, the Earl of Coventry secured premier honours with good Gros Colman and Muscat of Alexandria Grapes, a fine Smooth Cayenne Pine, a large Melon, and good dishes of Pears, Peaches, Figs, and Plums. C. Lee Campbell, Esq., second, with large bunches of Black Alicante and well coloured Muscat of Alexandria Grapes, a fine Melon, and good dishes of Pears, Apples, and Plums. Mr. E. Hall, Bath, was third. For four dishes Mr. D. Sheppard was first with good Muscat Grapes, fine Pitmaston Duchess Pears, Figs, and Peaches. J. P. W. Butt, E-q., a very good second. Lieut.-Colonel Rogers had the best Peaches; and C. Lee Campbell, Esq., and J. P. W. Butt, Esq., were the most successful in the Melon classes. The Earl of Coventry had the best dessert Apples, showing King of the Pippins; and Mr. H. Shurmer had the finest dish of culinary Apples, with magnificent examples of Peasgood's Nonesuch. The same exhibitor was also first for twelve dishes of Apples. In the vegetable classes Mr. G. Garraway, Mr. H. Shurmer, and Mr. A. Bevan took leading positions for collections. In the single dish classes the competition was keen, but it would take up much space to name them.

Mr. B. Ladhams, Shirley Nurseries, Southampton, was awarded a silver Flora medal for a fine collection of herbaceous flowers, also a first-class certificate for a perpetual-flowering Pink named Ernest Ladhams, which promises to be an acquisition. First-class certificates were awarded to Messrs. Perkins & Son for two beautiful Cactus Dahlias—viz., Purple Prince and Matchless. Messrs. W. Edwards & Son, Sherwood, Notts, exhibited their new bronze-like receptacles for Ferns or other plants. Mr. C. Phillips staged a miscellaneous collection of flowering and foliage plants. Mr. G. Humphries and Messrs. Heath & Son staged Dahlias in variety; and Mr. J. Townsend, Worcester, Dahlias and Roses, not for competition.

TRADE CATALOGUES RECEIVED.

E. P. Dixon & Sons, Hull.—Forest and Ornamental Trees, Shrubs, Fruit Trees, &c.

Dobbie & Co., Rothesay, N.B.—Hyacinths, Tulips, Roses, Carnations, Sec.

FRUIT FORCING.

Vines.—Early-forced Vines in Pots.—Those to be forced to furnish ripe Grapes in March or April should be started not later than the first or second week in November. Early and free fruiting varieties must be chosen. There are few that are in all points so satisfactory as White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court. If bottom heat can be given to start them they will break well. Provided there is a pit of 3 feet depth and 4 feet width, the pots may be raised upon bricks in pillar fashion, so that their rims are slightly higher than the pit edge, and so that the pots will be in the centre of the bed. Leaves being placed in to fill the pit a gentle warmth will be afforded the Vines, and the roots will pass from the pots into the leaves, deriving support beneficial to the growth of the Vines and Grapes. The temperature at the roots must be moderate at all times, especially at the commencement, 60° to 65° being sufficient about the pots and 70° to 75° at their base. When in growth the temperature about the pots ought to be between 70° and 75°. The house must be light, properly ventilated, and well heated. It should face the south, a lean-to or three-quarters span-roof being most suitable.

Early-forced Houses.—It is not desirable to start permanently planted Vines early in November to afford a supply of ripe Grapes in late March or April where there is convenience for growing them in pots, as it is a great strain on their energies through having to make growth at the dullest period of the year, and to rest at the hottest. The Vines ought now to be pruned, and rest assured by keeping them cool and dry. If the roots are partly outside that part of the border should have a covering of moderately dry leaves with a little litter to prevent them blowing about. This is an effective protection, and need not be used until the soil has been well moistened by the autumn rains, yet before the ground has become soddened and much reduced in temperature. Where the border is entirely outside and early forcing is practised it will be necessary to cover it with fermenting materials about the time of starting the Vines. Three parts of Oak or Beech leaves to one of stable litter will give a more suitable and durable warmth than all manure. The material need not be thrown into a heap until the house is closed, then mix well together, damping if dry, and when getting warm it is fit to place on the b rder. But Vines in outside borders are not desirable for early forcing, though it is sometimes necessary to make the most of them for the purpose, and in that case a supply of fermenting material must be held in readiness so as to renew the heat as required. Fermenting materials are also a great aid in forcing operations where the roots of the Vines are partly or entirely inside, as they generate and maintain a genial condition of the atmosphere, without recourse to so much fire heat or sprinklings from the syringe. In that case the material should be placed in the house when it is closed, turning the heap a time or two more than is advised for outside borders, so as to become well sweetened before being used.

Second Early Houses.—Vines to be started at the new year to afford ripe Grapes in late May or early in June ought now to be pruned and dressed, removing the loose bark only, and washing them with a tepid solution of softsoap, 2 ozs. to a gallon of water. The house also must be thoroughly cleansed, whitewashing the walls, and painting the wood and iron if necessary. Unless the Vines have been infested with insects it will not be necessary to apply an insecticide. If they have been attacked, it would be advisable to dress them carefully with an approved solution. The loose surface soil should be removed and a couple of inches thickness of fresh loam be supplied, sprinkling about 4 ozs. of the following mixture over each square yard-steamed bonemeal two parts, and kainit one part, mixed, and leave it on the surface, unless it is necessary to apply water to render the soil moderately moist, then of course it will be washed in, and the soil will hold its manurial elements. The house should be kept cool and dry, ventilating fully except when frost prevails, and only use fire heat to exclude it or prevent the hotwater pipes becoming frozen and burst.

Midseason Houses.—Where the Grapes are hanging it will be necessary to employ a little fire heat so as to insure a circulation of air and prevent the deposition of moisture on the berries, which is almost sure to be followed by decay. Air should be admitted constantly unless the weather is very damp or foggy, when it will be best to maintain a gentle warmth in the pipes and keep the house closed, not employing more heat than sufficient to keep the temperature at 45° to 50°. If the roof is a leaky one or plants have to be accommodated in the house, it is advisable to cut the Grapes with as much wood as can be spared, and, removing the leaves, place the shoots in bottles of clear rain water placed in an inclined position in a cool dry room, so that the bunches will hang clear of the bottles. Grapes in this way will often keep plump and sound up to Christmas, whereas left on the Vines they often decay long before that time, and the shortening of the bearing shoots to two or three buds above the pruning buds is often beneficial by plumping the latter, also by affording freer access of light and air. It is also a good plan to remove some of the laterals where they are crowded, but

this must not be carried too far where black Grapes are hanging or they

will lose colour through exposure to the sun.

Young Vines.—These often have a disposition to keep growing to a late period, and it should be checked by stopping the shoots moderately, but not so much so as to start the principal buds, as would be likely by large reductions at one time and too closely. It will also accelerate the ripening of the wood, which may be further facilitated by a somewhat high temperature and rather dry atmosphere by day, shutting off the heat and keeping the ventilators open by night except when frost prevails, for the Vines must not become frozen whilst they are full

of sap.

Late Grapes.—These are now thoroughly ripe except where the Vines are in bad condition, or where started late. In the latter case little benefit is derived from fire heat at this season in ripening the Grapes, but it should be used where the wood is not thoroughly ripened for the next year's prospects, maintaining a temperature of 70° to 75° by day and 65° at night, falling 5° through the night, allowing an advance to 80° or 85° from sun heat, continuing this until the Grapes are ripe, at least until the wood is brown and hard. Where the fruit is thoroughly ripe—as it should be, for in that condition only can Grapes be expected to winter satisfactorily—and the wood thoroughly matured, all spray or laterals may be removed down to the main buds, ventilating freely on all favourable oceasions. Fire heat will only be necessary to prevent the temperature falling below 50°. To prevent dust settling upon the berries raking or sweeping must not be practised. Mats or clean dry straw laid over inside borders will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. The outside borders must be covered if the fruit is to keep satisfactorily. Glass lights are best, wooden shutters good, and tarpaulin over dry bracken or straw answers well. About 6 inches thickness of dry leaves, and a little litter over them, is all that is given in many cases, and when the borders are well drained the Grapes keep plump and sound to a late period.

Melons.—Water must now be applied carefully to plants with the fruit advanced towards ripening, but those with fruit swelling must not be allowed to become dry at the roots. Keep up moderate moisture by damping for such plants, available surfaces being sprinkled in the morning and afternoon. Add a little soil to the hillocks of the latest plants as the roots protrude. Remove all superfluous growths as they appear, and maintain a temperature of 65° to 70° at night, 70° to 75° by day, up to 85° or 90° with sun. Keep the bottom heat steady at about 80°. Fruit ripening will be the better of a little extra fire heat and air constantly, which will do much to impart flavour. Any fruit it is desirable to keep for a time should be cut with a portion of stem, and be kept in a dry airy room. Fruits that are nearly ripe in frames may also be cut with a goodly portion of stem and be placed in a warm airy house in the full sun, and they will ripen better than in a moist atmosphere

or where there is a deficiency of warmth.

THE KITCHEN GARDEN.

Celery.—All things considered Celery looks remarkably strong this season, and the quality and keeping properties ought also to be satisfactory. Where there are partial failures this, in many cases, is largely due to want of moisture at the root. Ordinary rainfall bas little or no effect upon Celery in trenches. What the plants want are occasional thorough soakings of water or liquid manure, and that not merely prior to commencing to mould up, but also for some time afterwards. Before either the first, second, or even third addition of soil is banked up against the rows the soil about the roots should be tested with a pointed stick. If found, as it most probably will be, dry, or approaching that condition, give a heavy watering, and delay moulding up for another Unless these precautions are taken the Celery will be worthless before the season is very far advanced, and will seed prematurely.

Earthing up Celery.—The latest rows ought now to be partly moulded up. Pull away the small lower leaves and any suckers there may be, and either tie or hold the outer stalks well up together prior to placing about 3 inches of fine soil about them, re-loosening the stalks so as not to unduly confine the hearts. If slugs are troublesome, soot, or soot and lime, should be freely dusted among the plants before the first and subsequent additions of soil are made. In extreme cases it is a good plan to wholly surround the stalks with either fine dry ashes or burnt earth, Celery also keeping well when thus enclosed. A very large amount of these materials is not required if boards are placed well up to the rows when each addition is made, and soil being banked against to the boards; the latter can be withdrawn and shifted along to the next length. The moulding up of the earlier and successional rows should also be proceeded with, this being completed at about three times. Not till the hearts are well advanced, or say from a fortnight to three weeks after the previous moulding up, should more soil be placed against the plants. This should be made fine, and not pressed hard against the stalks, the latter being disposed so as to exclude the soil from the hearts. At the final moulding enclose about one-half of the leaves, making the soil rather firm about these with the hand, and round off the ridge so as to throw off heavy rains and snow water.

Cardoons .- These also absorb much moisture at the roots, and the stalks will be dry and tough if the plants suffer from want of water. Therefore give more water if necessary. In order to blanch and keep Cardoons effectually the best of the leafstalks ought to be gathered well up together, and kept so by means of haybands wound closely around It is rather rough work, but if the men are furnished with gloves and canvas jackets it can be easily accomplished. Bank the soil well up to the plants gradually, or much as Celery is finally moulded up.

Leeks.—When the plants are dropped into deep fairly wide holes, formed with a dibber, the blanching will be effected without any further trouble. Should the Leeks be planted in trenches or it may be nearly on the level then moulding up must be done. A bandage of strong brown paper or a common drain pipe split in halves placed round the stems would prevent the soil from finding its way down the leaves, but for ordinary purposes there is no necessity to take this precaution. Leeks are perfectly hardy, and need not be heavily moulded up, as in the case of Celery by way of a protective measure.

Onions.—Those which were either sown late last spring, or else failed to come up till very late in the season, have in many cases failed to "bulb" properly. When this happens, the necks are thick and the tops erect and green. Instead of pulling all up and attempting to ripen them sufficiently to store for winter use, the better plan is to pull those that have formed bulbs, the tops also being limp, and to finish the ripening of these, either in an old-fashioned oven after the bread is drawn, or else in a dry warm place under glass. Let the green Onions, or all that are still erect and growing, remain where they are, these being drawn according as they are wanted for use. They will being drawn according as they are wanted for use. survive an ordinarily severe frost, and in any case leaving them alone is the only way in very many instances of being sure of a supply of Onions.

Other Root Crops.—Beet, Carrots, Salsafy, and such like were restarted into active growth by the August rains, and are still growing strongly. Having plenty of strong leaves there is little likelihood of frosts injuring the first-named, and all will most probably keep better if

left where they are for a fortnight longer.

Spinach.—Winter Spinach is in a very promising condition. In many cases the seed germinated well, and unless the plants are freely thinned out directly the leaves are large enough to use premature seeding will take place. Stirring among the plants with a pointed stick and between the rows with a Dutch hoe are good preventives of grub attacks

and the increase of slugs.

Protecting Vegetables. - Globe Artichokes are stronger more plentiful than at any time previous this season. Seeing that they afford a good and well appreciated change it would pay well to protect some of the best of them whonever severe frosts are imminent. A single row or small breadth of plants could be easily protected by means of a few stout upright and cross stakes, these supporting mats or canvas covering. Odd plants throughout a large breadth might be roughly protected with large branches of evergreens securely fixed over them. Some of the more forward heads could be cut, and kept for a few days with their stalks placed in water. Autumn Cauliflowers and the earliest Broccoli are spoilt by a moderately severe frost; but it is rather too early to lift and store these under cover of some kind. All ought to be gone over frequently, strong leaves being gathered from old stumps and carefully tucked over the more forward hearts. Rows of medium height late Peas might be protected with blinds and such like, branches of evergreens also affording sufficient protection in some cases. Have sideboards fixed round breadths of late Lettuce and the more forward Endive, with sufficient cross bars to support light mats or other protective material whenever frosts are anticipated. Tomatoes against walls have formed extra good late clusters of fruit, and seeing that these will ripen better on the plants than off if properly protected. The leaves being healthy, and not cut back unduly, afford a certain amount of protection; but these ought to be supplemented by mats, blinds, or spare frame and pit lights. Should there be any signs of the disease commencing to spread, then ought the clusters of green and ripening fruit to be cut at once, and suspended in warm, dry quarters to colour. The larger green fruit will colour in due course, and be available for cooking purposes, but the small green fruit is only fit for pickling.

PLANT HOUSES.

Zonal Pelargoniums.—Plants that have been standing outside would now be better if they could be placed under cover. Avoid starting them into soft growth if the plants are to flower profusely and continue to do so for a lengthened period. Shallow cold frames will suit these plants for some weeks, so that the lights can be tilted or closed at night to protect them from frosts that may occur at any time. Protect the plants also from heavy rains, but on all fine occasions throw off the lights. If some plants are needed in flower arrange the forwardest in a light airy structure fairly close to the glass. Admit plenty of air to the plants, also give a little artificial manure to the surface of the soil. Do not overwater, for this proves as detrimental to the plants as heavy rains. Remove from all plants that are placed in frames early flowers that are already showing, also bad leaves. Late propagated plants now in 3-ineh pots that have been kept in frames may be placed into slightly larger pots, and if kept in frames, or in a light airy house where they can be given a little warmth, they will produce flowers for a long time.

Ivy-leaved Varieties.—These are most useful, and if they are well ripened by standing outside and are housed at once they will yield flowers for some time. However useful the Zonals may be the flowers of Ivy varieties are very effective in a cut state, especially the delicate

shades of pink.

French and Fancy Pelargoniums.—These may be placed in their winter quarters, such as on shelves close to the glass in cool, airy houses. In these positions with careful watering the plants winter well. The earliest plants should have the points of the shoots removed before they are placed on shelves, and if in 3-inch pots they can be placed into 5-inch pots. In potting firmly press the soil, which should consist of

good fibry loam, one-seventh of sand, and the same amount of manure. Careful watering is necessary, for if kept too wet the foliage is certain Later plants should be treated the same as regards air and water. Young plants that are established in 3-inch pots may have the points of any weak shoots removed; pinehing will induce them to start strongly again into growth, provided they are kept cool. Cuttings that are still in outside borders should be lifted and potted without delay. All that are rooted should be placed into 3-inch pots, and stood on shelves in a cool house. Heat ruins these plants by causing them to

Heliotropes.—If the plants are placed in a light, airy structure, where the night temperature can be gradually increased to 55° in a month's time, the plants will commence growth, and flower profusely for a very long time. A little artificial manure applied to the surface

will prove beneficial.

Bouvardias.—These plants must not be starved. Any that have been planted outside and are only needed for providing flowers may be lifted with good balls and put in a warm frame or low house. Those grown in pots will be showing flower, and if stood in a house where gentle warmth can be given in the course of a few weeks they will soon yield useful flowers for cutting. If placed on ashes the plants invariably root through, and this proves a great assistance to them. Soot water, or artificial manure that acts quickly, proves invaluable to these plants.

Justicia flavicoma.—The growth of these plants is earlier than usual, and already the flower truss in many cases is just visible. A temperature of 50° will suit them, plenty of air being admitted during fine warm days. Soot water and artificial manure may be given. plants if raised from cuttings should be clean, but if scale exists upon

them it ought to be eradicated.

Fuchsias.—Plants that have flowered and have thoroughly ripened wood may be stood outside for a time. Younger plants that have not the wood well ripened may be stored for a time in frames. Do not hurry them to rest by keeping them unduly dry. Young plants that are just rooted may be placed into 3-inch pots and arranged on a shelf,

where they can be kept growing during the winter.

Bulbs.—Various kinds of bulbs should be potted according to the demand until the end of this month. When placed in ashes they should be marked, and the date of potting placed on the label. This saves trouble and disturbing the plants before they are ready for removal. Place all the later potted ones where they can be covered with litter if not ready for removal before we experience severe weather.

Freesias.—All the earliest of these should be growing in frames, where they can remain for some weeks longer. If the frames are needed place the plants on shelves where they can enjoy full sunshine and plenty of air. Freesias are frequently spoiled by a too close confined atmosphere. Later plants must not be allowed to become drawn.

APIARIAN NOTES.

PRACTICAL HINTS FOR BEGINNERS.

(Continued from page 299.)

WITH the exception of depositing the eggs in the cells, which is done solely by the queen, one in each cell, and at the rate of from one to four thousand or more daily, all the other economy of the hive is performed by the workers gathering pollen and honey from the flowers and other sources.

They secrete wax in the form of irregular roundish white scales, which when ready for use project from the segments of their stomachs in pairs. This they utilize for building and sealing their honeycombs, and with a mixture of it and pollen and propolis, they cement crevices of the hive, and seal their brood cells. While they perform this work with ardent care and zeal for the future generations of bees, their work in the field is perhaps of greater importance. Entering blooms for honey and pollen ostensibly for their own use, they fertilize and cross flowers, perpetuating them with greater vigour and beauty. Probably some buds would never expand did the bees not remove the superabundant propolis from them; everywhere and in everything the bee is engaged.

The drones are the male bees, which are sometimes too numerous in hives; advice to their restriction will be given further They are of no use in the hive, unless it be in the case of swarmed hives, where there are a paucity of workers to keep up a proper degree of temperature for the successful hatching of the young bees. In the season of mating they fly out during the warmest part of the day, from one till three being the busiest time. They remain out from fifteen to thirty minutes, flying long distances in hopes of meeting and mating with a queen. During the present summer, while I held a queen, a drone, probably attracted by her odour, flew right into my hand. The speed drones fly at probably exceeds greatly that of the worker, which has never been properly estimated. While standing in an open truck this

year, the engine going upwards of fifty miles an hour, the bees flew from front to rear, evidently with the greatest ease.

Fertile workers are so called because externally they cannot be distinguished from a worker bee, but in the proper sense are imperfected queens. They cannot mate, and were until recently considered utterly worthless, producing, like unfertilised queens, drones only; but these are as perfect as are the drones of fertilised queens. So far back as 1862 the late Mr. T. W. Woodbury proved this by one of them mating with an Italian queen, and I have had experience of many cases since. Their existence seems to be a wise provision in nature, the drones produced from them serving queens at times when no other drones exist. I am not certain, but it appears to me that a queen may be the mother of drones, to be fertilised by one of them, and then be the parent of strong Several cases in my experience point to that being the case; but why workers rear many of these sumptuously in queen cells is a mystery to me. I have never been led into the erroneous opinion, as have been many others, that they were eggs moved by the bees which do not carry eggs from cell to cell. The hermaphrodite is part bee and part drone. The beginner studying these brief but necessary hints will have less difficulty in understanding the proper condition of his hives than if he had allowed ignorance to hold its sway.

BEGINNING BEE-KEEPING.

There is perhaps no better period to begin than at the present time of the year, because by proper management and paying attention to advice given in these pages, most of the after success depends. Beginners should select a good site and locality to keep bees. Size of hives is of great importance. Those of less dimensions than 3500 cubic inches are too small. One prominent bee-keeper told me recently, "I have kept to the three divisions since you at first advised me, when I abandoned the 'Standard' hive, and I have always had more honey, and better of quality." "R. A. C., Kent," writes that his Lanarkshire hives have given him in every case 20 lbs. more honey, and I could quote scores of similar cases.

Youthful queens are what beginners ought to tolerate only, unless where there may be a valuable imported or pure bred one kept for the sole purpose of breeding from. The best time to do this is from the end of May till the end of July, and there is no better way, failing a swarmed stock, than to deprive a strong one of its queen. In ten or twelve days queens are hatched, and then it may be formed into nuclei; twelve from a strong stock may thus be formed. The frames with bees having a queen cell to each lot may be put into roughly made light boxes of a suitable size to hold from three to four or more frames. What is not occupied with combs should have frames filled with foundation. cover screwed on the top completes the arrangement, when they may be set on their site in the apiary, or isolated five to seven miles from other bees for select fertilisation. Put a piece of waterproof over them, and await development.—A LANARKSHIRE BEE-KEEPER.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Exhibiting Tomatoes (A. Creek).—In the absence of any special intimation in the schedule that Tomatoes may be included in a class for fruit, a collection containing them would be open to disqualification. Like Cucumbers and Vegetable Marrows, Tomatoes are exhibited in vegetable, and not in fruit classes.

Blinds in Fruit Room (F. J.).—The blinds suspended along the front of the shelves for excluding light from the fruit would not exclude air to the prejudice of Apples and Pears in a reasonably ventilated room, but it might be necessary to block up the window during severe frost if such occur in your locality.

Soft versus **Hard Water** (T. A.).—We regret your communication, arriving rather late, cannot be inserted this week because written on both sides of the paper. When the writing is on one side only the sheets can be cut into a number of strips for distributing among compositors, and the whole matter is set in type quickly, otherwise, as in this case of yours, the process is of necessity slow. All matter intended for publication should be in accordance with our standing request at the head of this column.

Turfy Loam for Peach and Vine Borders (H.G.W.).—No. 1 is probably the richer soil of the samples, being of a darker colour through the vegetable matter, and contains less grit than the others. It would no doubt answer for the Alicante, Lady Downe's and similar varieties with an admixture of one cartload of old mortar rubbish, one cartload of dry wood ashes, and 4 cwt. of crushed bones ($\frac{1}{2}$ inch to 1 inch) to ten cartloads of the loam. No. 2 is an excellent brown or hazel loam, but deficient of gritty matter, yet it may be made available for Peaches by adding to it one-sixth of clayey marl and a similar proportion of calcareous gravel, with $\frac{1}{2}$ cwt. of kainit and $1\frac{1}{2}$ cwt. of basic slag (Thomas' phosphate) to ten cartloads of loam. The clayey marl should be dried and pounded, incorporating all well together, and making very firm. No. 3 would answer for the Muscats, as it contains more grit than the other samples, yet not enough; therefore to ten cartloads of the loam add two of old mortar or lime rubbish, one of dry wood ashes, one of fresh horse droppings, and 4 cwt. of crushed $\frac{1}{2}$ to 1 inch bones, mixing well. The proportion of Thomas' phosphate named above may be added with advantage.

Apples and Pears from Seed (An Old Subscriber).—The seeds pips which have been selected from first-class fruit during a recent visit to Normandy should be sown now in an open situation, preferably in drills about an inch deep and about 6 inches asunder, or the seed may be kept in sand and sown early in the spring. Some persons sow the pips in pans, and cover them with small-meshed wire netting to exclude mice. In the autumn after sowing the seedlings may be placed in nursery rows about 1 foot asunder, and the plants 6 inches apart in the rows after shortening the tap root and assorting the plants into sizes. The autumn following they may again be transplanted if they require more room, planting in rows 42 inches apart and 2 feet asunder in the rows. Further transplanting will be necessary as the trees require more room, always allowing sufficient space for the sun to reach the ground, and for light and air to have free access to the growths. The transplantings will accelerate fruiting, or it may be furthered by grafting the seedling Apples on Paradise and the Pears on Quince stocks. The age at which seedlings commence bearing varies from five to twelve years, the period depending on the variety; but the time is greatly influenced by soil, situation, and mode of culture. Probably one seedling in a hundred will not afford fruit equal to the parent, but it is possible that something good may be secured.

Artificial Manure as a Substitute for Natural (F. J.).-There is really no substitute for animal manures, simply because they contain matter which, as humus, adds to the staple and improvement To keep the soil in a fertile condition is another thing, and may be effected by the judicious use of the substances containing the needful elements as food for plants. These are mainly phosphoric acid, potash, and nitrogen. Superphosphate supplies the first, also lime, and some nitrogen; kainit furnishes potash, soda, and magnesia, but is mainly useful for its potash; and nitrate of soda contains the essential The phosphoric acid and potash must be in the soil for the nitrate of soda to act beneficially, for in their absence the nitrate may be worse than useless. Two parts superphosphate and one part kainit, mixed, may be applied very early in the spring at the rate of 4 ozs. per square yard, and when the crops are fairly above ground, or have taken to the soil, supply nitrate of soda, finely powdered, at the rate of half to three-quarters of an ounce per square yard. For fruit trees the superphosphate and kainit mixture may be applied in the autumn, when the leaves have fallen, the trees pruned, and just before pointing the ground over lightly. This will be in November or December, but it must not be given later than February, then in the spring sprinkle on the nitrate of soda. All the manure should be spread from the stem outwards to 1 foot beyond the extension of the branches.

Pinus insignis Shoots and Buds Destroyed (E. B.).—The caterpillar is that of the Pinc-bud moth (Retinia turionana), which feeds in the buds and of course destroys them. The only remedy is to cut off all the infested parts and burn them. The earlier this is done in the season the better, so as to give chance of the formation of new buds, which sometimes occur on the shoots that lose their growing We find the best preventive is to coat the trees subject to the attacks of the pests early in July with a petroleum mixture, so as to render them obnoxious to the moths, and thus prevent them depositing their eggs. The beetle is Hylurgus piniperda, which emerges from the tunnel or pupa state from June to September (for there may be two broods) and bore into a young shoot and eat out the pith in the centre, from the base towards the tip. The shoot dies, dries up, and When a number of shoots are affected the consequences are very disastrous. There is no better remedy than to cut off the affected shoots just below the holes and burn them, or a petroleum emulsion may be ejected into the holes, but unless this is done before the beetles reach the pith the benefit beyond destroying the beetles is not material as regards the attacked parts. It is also advised to syringe the trees with a petroleum mixture so as to render them distasteful to the beetles. A fluid ounce of petroleum to 3 gallons of water is sufficient, and it is more efficient when 6 ozs. of softsoap have been dissolved in that quantity of water, keeping the mixture well agitated whilst being applied, which should be on a dry day, and through a fine syringe.

Applying Dissolved Bones and Kainit (T. W. F.).—It is necessary to take all the circumstances into consideration, and supply the manures so as to meet the needs of the crops. This was taken into account in your case consistently with the information supplied, which practically amounted to the soil being deficient in phosphoric acid and potash. It was because we thought it desirable to supply these essentials, so that they would be available for appropriation as early as possible in the spring, that we advised the autumn dressing when the ground is being pointed over or lightly dug before the winter. We did not mention September. What all practical fruit growers know as autumn digging among fruit trees is not done then, but after all the leaves are fallen from the trees. This is in November or early December. Applied then, the loss from the mixture would be trifling—a modicum of nitrogen perhaps, the phosphoric acid and potash being retained and ready for use on the first opportunity. When spring dressings are ready for use on the first opportunity. When spring dressings are advised, some fruit growers have such a dread of losing anything that they apply the mixture too late for benefiting the season's crop, and at the same time prejudice the succeeding year's prospects by inducing late growth. Generally speaking February is a very good time for applying chemical manures to fruit trees that need them, and the advice given in the work you name is perfectly sound. Your case was regarded as special, but if you prefer to apply the manure in February to avoid a possible trifling loss in the winter by all means do so, but we should then use two parts of bone superphosphate and one part kainit. Late autumn dressings of mineral ingredients are much more effectual than late spring applications, and those used in March and April this year did not do half so much good as did those applied in the preceding autumn, the possible loss of a modicum of these notwithstanding. soda need not be given unless a heavy crop of fruit sets, when it should be supplied without delay, for without nitrogen in adequate quantities maximum values cannot be had from the other elements, and nitrate of soda is simply wasted unless the soil contains sufficient phosphoric acid and potash. Kainit contains about 23.43 per cent. of potassium sulphate, and a good quality kainit should contain from 12 to 14 per cent. of potash.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only speciment and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (I. W., Pershore). — Herefordshire Beefing. (C. D., Wales).—Cox's Orange Pippin. (B. J.).—Beurré d'Aremberg. (C. J.).—Cornish Gilliflower. (W. S. Payne).—Dumelow's Seedling. (H. Neal, Stapenhill)—1, Maréchal de Cour; 2, Doyenné du Comice; 3, Marie Louise; 4, Comte de Lamy. Please do not use needles to affix the numbers; they are dangerous, and some of your numbers were displaced, therefore the fruits cannot be named. numbers were displaced, therefore the fruits cannot be named. (W. Carr).—1 and 6, Van Mons Leon Leclerc; 2, Quite hard and unripe; 3, Doyenné Boussoch; 4, Duchesse d'Angoulême. (T. S. Inch). unripe; 3, Doyenné Boussoch; 4, Duchesse d'Angoulême. (T. S. Inch).—
1, Souvenir du Congrès; 2, Nouveau Poiteau; 3, Josephine de Malines;
4, Maréchal de Cour? decayed; 5, Fondante d'Automne; 6, Quite
hard, and not known. (J. H. R.).—1, Beurré Beauchamp; 2,
Beurré Capiaumont; 3, Comte de Lamy; 4, Marie Louise. (W. R. R.).
—1, Ribston Pippin? not a typical specimen; 2, Certainly not
Ribston—graft the tree; 3, Beauty of Kent. (O. E.).—1,
Dumelow's Seedling; 2, Greenup's Pippin; 3, Gravenstein; 4,
Lewis' Incomparable; 5, Winter Majetin; 6, Kentish Fillbasket. By
driving nails into the eyes of Apples for fixing the numbers, you destroy
one of our aids to identification. (I. Stephens).—The large fruit is driving nails into the eyes of Apples for fixing the numbers, you destroy one of our aids to identification. (I. Stephens).—The large fruit is Kentish Fillbasket; the small one Winter Queening. (W. J. G.).—All the specimens are inferior. 1, Golden Reinette; 4, Swan's Egg; 5, Possibly Bergamotte Esperen. (G. Orpen).—1, General Todtleben; 2, Flemish Beauty; 3, Susette de Bavay; 4, Swan's Egg; 5, Fearn's Pippin; 6, Ross Nonpareil. (J. S. Bailey).—1, Court Pendu Plat; 2, Cox's Orange Pippin; 4, Franklin's Golden Pippin; 5, Beurré Bosc. (G. C.)—Sorry we cannot identify the Apple, especially as it is a good one. (W. P.).—We suspect these to be local seedlings, of greater one. (W. P.).—We suspect these to be local seedlings, of greater promise than the majority and have no recognised names. (F. J. Gray).—1, Dumelow's Seedling; 20, Melrose; 21, Wyken Pippin; 25, Blenheim Pippin; 31, Annie Edzabeth. (H. Hunter).—1, Not recognisable; 2, Blenheim, a grand specimen; the Pear is Beurré Hardy. (C. Russell).—1, Remette de Canada; 2, Ditto; 3, Probably a small Hollandbury; 4, Not recognisable; 5, Greenup's Pippin; 6, Small's Admirable. 4, Not recognisable; 5, Greenup's Pippin; 6, Small's Admirable. (J. H. C.).—1, Duchesse d'Angouléme, the others quite hard, and not in condition to be named. Pears should be sent on the change towards ripening. The above are all the fruits we received up to midday on Wednesday.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (William Smith). — Scabiosa caucasica. (H. M.). — Aster amellus. (L. B.). — Colutea arborescens. (Amateur).—1, Hoya carnosa; 2, Plumbago capensis. (F. D.).—Habrothamnus elegans. (W. D. H.).—The Powdery Mullein (Verbascum pulverulentum). (James Carolan).—The letter to which you refer as having been posted on the 18th ult. has not reached our hands, nor have we received any specimens from you. (J. J.).—Dendrobium album; Rhododendron Javanico-Jasminiflorum var. Duchess of Connaught. (J. W. B.).—Lathyrus sativus. (G. C.).—Florist flower; can only be named by comparison.

COVENT GARDEN MARKET .- OCTOBER 4TH.

A WHEAT STRAW.

ONLY a Wheat straw, pulled in an idle mement from a waggon load of it which we passed on the top of a 'bus in a busy London street! Yet a mere glance at it was sufficient to arrest the attention entirely, so strikingly did it serve to illustrate the lamentable condition of corn crops this year on many a farm. It did more. The very fact of its having been sent into market so soon after harvest told of straitened means,

of the urgent need for money that farmers have; and its miserable appearance showed also how small an amount the entire crop both of corn and straw would realise. Very little over a foot in length, not broken, but clean cut by the reaper at the bottom, and as slender as short, it showed how poverty of soil had rendered it unable to withstand the severity of a drought through which corn on land rich in fertility has passed comparatively unscathed. It is quite possible that late sowing in badly worked soil also contributed to its meagre appearance. Whatever may be the causes affecting its growth from seed germination to crop maturity, the lesson taught by it deserves our serious attention.

Is the production of so trashy a crop worth while under any circumstances in this country? No; it is not worth while. Nothing can make it so; not even the exigencies of the present season, when every scrap of fodder has been collected so eagerly, and the bulk of it on many a farm falls so short of the farmer's requirements even for home use. However regarded, the matter resolves itself into a question of profit and loss. It is just a business transaction and nothing else; nothing can be more simple. Profitable farming has nothing sentimental about it. It means a clear gain upon expenditure, a fair interest upon capital invested in the tillage, cropping, and stocking of the land, for which a rent of so much per acre is paid. Every acre must therefore yield enough produce to pay sufficient interest to keep things going—a fair margin of profit. For this to be possible under stress of falling prices and foreign competition there must be judicious cropping, as well as thorough cultivation. It is questionable whether our Wheat straw had either advantage. No doubt it would have been of much more robust proportions had soil fertility been well sustained on the farm where it was grown. But it has come to this with us in Wheat growing, that it is only profitable under every advantage of seed selection, the best mixed soil, thorough timely cultivation, and the possibility of selling both the straw and corn. The straw is now almost as valuable as the corn, a ton of straw being equivalent on the market to 24 bushels of Wheat.

Do we quite realize what foreign competition means? Surely not, or the wild, hopeless endeavour to grow Wheat on poor half cultivated land here would cease. Take one example out of many, that of Manitoba; there Wheat-growing continues to be remunerative under the present cash price of 50 cents., or 2s. per bushel, because it is grown at an average cost of 1s. per bushel. Something considerably beyond the average is realised on the best land where the yield rises to thirty or even thirty-five bushels an acre in favourable seasons. There are thousands of acres of virgin soil as good as the best of this country not yet brought into cultivation. Nor is Wheat-growing in the Far West nearly so speculative as is commonly supposed. From 1882 to 1892 there were six good crops, and four inferior ones owing to drought and frost.

It is estimated that this year Manitoba will export 24,000,000 bushels of Wheat, which certainly implies a very comfortable sum being paid to the settlers. Another thing to be remembered is, that in all good seasons, Manitoba Wheat is superior in quality to our home grown produce. On that vast continent, summer heat, though brief in duration, has an intensity hardly realised by us. There, growth advances so fast in June and July that Wheat sown in May may be ready for the reaper in August. Heavy rainfall alternating with long hot days in May and June induces growth of such extraordinary vigour, that crops are up and fully grown in a wonderfully short time. Then in July comes more settled dry and very hot weather, with many brief thunderstorms, accompanied by heavy rain, then Wheat ears develop and mature in a manner which would be thought marvellous in this country, and in all good seasons the reaper is at work by the third week in August. Clearly then our Wheat straw with the grain it carries must be of the best for the grain to retain a place on market in competition with that grown in the Western States as well as in India and other countries.

WORK ON THE HOME FARM.

Glad were we to hear from an energetic correspondent farming 2000 acres of land that by bringing his steam cultivator into full action immediately after harvest, and keeping it going daily, he had got the whole of his arable land clean, and either ready for sowing with winter corn (which was being done when he wrote to us), or thrown up for He also said that he had fed, sold, and got the money for upwards of 4000 pigs already during the current year. We told long ago of a tenant of our own who paid all the labour of his three farms with his "pig money." With cheap corn and dear pork every sensible farmer has largely increased the number of his store sows. It is men who meet the times promptly, making judicious changes, and throwing their whole energy into the work, that continue fairly prosperous.

Well, now, a set of steam tackles is only to be met with occasionally, but much may be done, much has been done this autumn by keeping horses and men going at full pressure. Some extra corn, extra pay, the master's eye and hand guiding and leading has told so well that the on-coming of winter will be welcomed. Severe weather will probably set in early (3 inches of snow fell in Cumberland on the 24th of September), and it will be well to clear roots off the land tolerably early in October. Mangolds ought certainly to be in clamps before the end of the month. To all who resolve to increase their swine stock we say, Resolve to keep them and their surroundings thoroughly clean. It pays. Filth retards growth, engenders disease, and eventually leads to those disastrous outbreaks of swine fever which are so ruinous and altogether deplorable. Breed well, keeping only young compact sows, paying especial attention to the selection of a pure-bred male parent; a Middle hite answers best for porkers, and porkers really well bred and well fed, weighing about 50 lbs. when dressed, have proved more profitable with us than any other class of swine.

NEW ZEALAND-A WARNING TO FARMERS.

SINCE 1874 the profits from farming land in Great Britain have diminished so steadily and surely, that few men can now obtain a commercial return on the capital in the occupation therein, and many are not able to make ends meet, even with such assistance as owners are able or willing to render. The home papers, which I read as eagerly as when living in England, show that numerous panaceas are offered to the farming public by those of their own craft and by city tailors. Some might be useful, but I cannot see how the farmer can live as in the past now that British enterprise has brought to his own market the produce

of the virgin lands of the whole earth.

During my twelve years' experience as a successful New Zealand farmer I have had wide opportunities of forming an opinion of my fellow colonists' abilities in that direction. My sole object in writing this is to warn farmers not to be misled by the colonising agents, who, in professing to be the friends of the poor farmer, are far more interested in disposing of the large areas of land which now lie as an incubus on the banks and loan companies, greatly aggravated by the crushing graduated land tax. A British farmer landing in New Zealand with his family and a few hundred pounds, but without the necessary colonial experience, will most surely live to regret leaving the old country. Suppose he lands in Auckland. He will have to find a house, food, and fuel, at a cost of £2 to £3 a week, until he can look over the offered land, perhaps 150 miles away, and by the time he has satisfied himself his capital has considerably diminished ere disappointment and failure begin. only men whom I advise to emigrate are farmers' sons who can bring money, powerful limbs, and a stout heart. These alone are the men who have a chance of success. Let them place their money in the Post Office Savings Bank and go to work at the lowest rung of the ladder.

Many of my fellow colonists would strongly object to my showing the intending emigrant farmers the rocks ahead. They would say "Let them come and find it out for themselves, as others have; we require money and population." I am first an English farmer, the only son of a long line of octogenarian tenant farmers, and I feel that it is my duty to warn men who have some years' experience of the dear old country, and probably families of young children, not to leave home unless they have

brothers here to care for and direct them.

Thousands of men during the land boom, the offspring of the huge borrowing and squandering policy of Sir Julius Vogel's Ministry, bought up far more land than they could profitably occupy, much of which would be dear at a gift. These broad acres must be got rid of by hook or crook, and many hooks and crooks have been invented to secure the unwary. I think I know most of them. One only need here be mentioned as a sample. A land agent took me over an estate which was for sale in the North Island. There were on it a few hungrylooking calves roaming at will, the only cultivated land being a small field, in which grass was just coming up. This was shown to me as a fair sample of what the soil could produce when improved by cultivation. Finding a Government engineer laying out roads close by, I stole a private interview, and gathered from him that, along with the grass seeds, half a ton of finely powdered bones had been sown per acre. I escaped; but the next man was hooked.

I rejoice to say that very many farmers are prosperous and contented; but they are, for the chief part, such as I have previously described having bought up land at from 5s. to 40s. per acre, and, by years of unremitting toil, fenced, cultivated, and built homesteads. When

Wheat was worth twice as much as it is at present, they were able to pay off the whole or part of the mortgages, and now wool and the frozen meat trade enables them to live in ease and plenty. At present selling prices of that land the purchaser would have as hard a time of it as the British farmer, and moreover, would have to reckon with the moneylenders, who are a different race of beings to the average English and Scotch landlord. Good farms within easy distance of a shipping port are realising from £20 to £40 an acre. If your climate were equal to this, I believe that many colonial farmers would emigrate and take up land at home.—SENTINEL (in the "Field").

ACORN POISONING.

THE following circular has been sent to us by the Board of Agricul-

ture, 4, Whitehall Flace, S.W.:—

The attention of the Board of Agriculture has been called to the unusual abundance of the crop of Acorns this season, and it is considered desirable to warn stockowners who are accustomed to turn cattle into parks, on to commons, or other places where Acorns are plentiful, that there is considerable risk of injurious effects arising from the consumption of large quantities of Acorns, which in the present dearth of herbage, owing to the long drought, are certain to be eaten with avidity.

In the years 1868, 1870, and 1884, which were remarkable for a large yield of Acorns after a long dry and hot summer, serious losses among young cattle occurred from outbreaks of what is known as the Acorn disease, or Acorn poisoning. In many districts, notably in Middlesex, Kent, Hertfordshire, Warwickshire, Lincolnshire, Northamptonshire, Wiltshire, Gloucestershire, Devonshire, the New Forest, Sussex, Surrey, Suffolk, Norfolk, and Derbyshire, extensive outbreaks of the disease occurred. Young cattle up to two years old suffered most severely. Milch cows and cattle over three years old were selected. affected. Sheep and pigs appeared to be unsusceptible to the poisonous action of the seeds, and only two or three cases of the disease were reported in these animals, while entire herds of young cattle were attacked and a large proportion of them succumbed.

Acorn poisoning is quite distinct from indigestion due to eating an excessive quantity of Acorns. This accidental disorder may occur in ordinary seasons when animals are first allowed access to pasture where Acorns abound. But the true Acorn disease is distinguished by progressive wasting, entire loss of appetite, diarrhoa, discharge of an excessive quantity of pale urine, sore places inside the mouth, discharge from the nostrils and also from the eyes, which are always sunken, giving to the animal a peculiar haggard expression. No fever is present from first to last, but, on the contrary, the temperature is commonly below the normal standard.

On post-mortem examination it is frequently noticed that all traces

of the Acorns have disappeared. The morbid changes are such as are seen when an irritant poison has been given.

Remedies of various kinds were tried in the great outbreaks of the disease, but no cure was discovered. Prevention is comparatively easy when the risk is realised. It is only necessary for absolute security to keep cattle from the pastures while Acorns are falling. The danger will be materially lessened by collecting the Acorns from the pastures, but this device does not prevent a considerable consumption of the nuts which fall during the night. It has also been suggested that when cattle are only allowed access to Acorns during the daytime they should be supplied with a liberal allowance of food before they are turned out. It cannot be affirmed that these plans have always proved successful in practice.

REMARKS.

REMARKS.

24th.—Almost unbroken sunshine by day; brilliant moonlight night.

25th.—Frequently sunny in morning; generally overcast in afternoon; spots of rain from 4.30 to 6 P.M.; moonlight night.

26th.—Overcast early; generally sunny after 11 A.M.; spots of rain about 6 P.M.

27th.—Rain from 1 A.M. to 4 A.M., and showers after; generally sunny during day, and bright night; lunar halo.

28th.—Sunshine early and solar halo from 8.30 to 9.30 A.M.; overcast from 10 A.M., with frequent spots of rain, and showers in afternoon.

29th.—Bright sunshine and high wind almost throughout; spots of rain once or twice in the afternoon, and rain at night.

30th.—Overcast till 10.30 A.M., bright and breezy after; sharp shower at 1.5 P.M., but uninterrupted sunshine.

A touch of frost on grass on the morning of the 24th, but on the whole a mild fine

A touch of frost on grass on the morning of the 24th, but on the whole a mild fine week.—G. J. SYMONS.

SPECIAL interest attaches to Tomatoes this season, for it has been an altogether exceptional one in respect to natural advantages, and consequently the crops have been abundant. Remunerative returns have been secured throughout the season, these varying, as they always will do, according to the market and the quality. At the middle of July a capable grower in the midlands told me that he had been securing 1s. a pound up till that time, and although the majority of the cultivators in the south who supply the principal London markets have not realised so much, their returns have been consistently good, and they will have cause to look back upon 1893 without the sadness and regret which tinge their recollections of some previous seasons.

It is disappointing, to say the least of it, that when the Eden of the Tomato growers was at its fairest a new serpent should have entered. Phytophthora infestans and the Cladosporium have often proved their capacity for giving quite as much trouble and embarrassment as most growers are able to cope with, and the advent of a fresh enemy in the Bacterium Halstedi, so graphically described by Mr. Abbey a few weeks ago, is something approaching the nature of the proverbial last straw. In all likelihood this bacterial affection of the Tomato is quite unknown to the majority of the growers, and especially to such of them as consider themselves quite above the necessity for reading the papers; but it is quite likely to spread widely unless something of its cause and origin are known. All cultivators are not open to knowledge when it is imparted as the result of microscopical investigation. For one reason or another they connect such inquiry with abstruse and devious scientific calculation that has not, and never can have, any practical bearing. There is certainly justification for such a view in some cases, but I venture to think that where the investigator is not only a scientist, but a thoroughly practical gardener, what he has to tell us is deserving of the most careful consideration. Some of the market growers, as well as a number of private cultivators: are of the same opinion, and I happen to know that the success of Mr. Abbey's able inquiries into the Tomato disease and the Chrysanthemum mite have attracted the attention of some of the best and most enlightened of our cultivators.

About the middle of August Mr. Wood, foreman to the energetic Kentish market grower, Mr. E. Vinson, wrote-"I have been reading the correspondence on Tomatoes dying in the Journal of Horticulture, and if you could give me a call you would see for yourself what the disease is capable of doing. We have 8000 plants in one block of houses, three parts of them dead; in another block over 8000 plants carrying a grand crop, and we have not lost fifty plants out of the latter. If you will come I will give you my views of the cause." I took an early opportunity of going, and saw what I can only characterise as a very remarkable sight. First let me say that Mr. Vinson is not a Tomato man merely. He is a large Hop grower, and has numbers of acres of Strawberries, Raspberries, Potatoes, Scarlet Runners, Cauliflowers and others. Probably there is no more enlightened and energetic man in the whole trade. He grows many things and does them all well. In the case of Tomatoes it would be very difficult indeed to find better grown plants than his. Those in the fruiting batch were splendid examples of culture, being stout, sturdy, short-jointed examples, bearing almost from the ground to the ridge of the house. There were about twenty-five houses of Cucumbers and Tomatoes, but the latter were the most strongly represented. The variety chiefly grown is Earliest of All, which is well known to be a very free setter, but has more or less corrugated fruit. In this case it is, however, found to sell well so long as good and well coloured fruit is sent to market, but it may be noted that there is a great deal of variation exhibited by the fruits, some being very much smoother than others.

I draw attention to the good quality of the fruiting plants, because I want to make it clear that Tomato growing is well understood by Mr. Vinson's foreman, and that the loss of so many plants from the disease which Mr. Abbey has told us about is not due to ignorance of the wants of the plant. That the disease is Bacterium Halstedi there can be little doubt, and Mr. Wood was of that opinion from the moment of reading the article on page 471, June 15th, 1893. The plants went off exactly as there indicated, beginning to droop as a rule just when the first bunch of fruit was swelling, as though they were too feeble to undergo the strain. There was the browning of the wood under the skin at the base of the plant, which gradually spread upward, and soon the whole of the foliage was wilted and drooping. The spectacle they presented as they hung withered and lifeless was a most melancholy one, and the wholesale manner in which they had gone off was a striking testimony to the potency of the minute

The questions now arise: What causes the attack, and can it be averted in any way? These queries are of the greatest moment to all classes of cultivators, and particularly to those who grow Tomatoes as a means of livelihood. If the disease is capable of carrying off thousands of plants in the hands of a really capable man, what guarantee is there that it will not deal out similar destruction to those of others, and so become a most formidable enemy? I might go even further, and without wishing to pose as an alarmist, ask what security we have against the disease becoming as terrible an enemy to Tomatoes as the Puccinia was to Hollyhocks, rendering their successful cultivation almost an impossibility. Fortunately Mr. Wood is not a rule of thumb grower, but one who uses his brains, and he has paid the closest possible attention and given the utmost consideration to the task of finding out the true cause of the attack which has rendered a large proportion of his work futile and entailed no inconsiderable loss on his employer. And he has been rewarded by what he thinks to be a complete solution of the problem. The explanation turns on a purely cultural point, and may perhaps be too simple for Mr. Abbey to accept, but such as it is I draw attention to it for the benefit of others.

Excess of moisture is at the root of many fungoid attacks, but it is the opposite condition which the Kentish grower holds responsible for the bacterial attack in his Tomatoes. He holds strongly that drought is as much the predisposing cause as soddening is of the Phytophthora, and in support of his argument he points to the differing condition of two sets of plants. One was put out after Cucumbers had occupied the space last season. The soakings the latter received resulted in the ground becoming thoroughly saturated. Here the Tomatoes have done splendidly, bearing heavy crops of fine fruit, and very few plants have been lost. The other set, where such havoc has been wrought, were planted in compost placed on a dry subsoil. They have been watered, but owing to the terribly parching season the lower soil has never been completely soaked, and here the Tomatoes have gone off wholesale. These facts are very significant, and even if everybody does not accept them as a solution at once they will doubtless admit that "there is something in it." As affording further evidence of the great benefits of an adequate supply of water Mr. Wood pointed out how much better and more fruitful the Tomatoes which are near the tanks, or near a leaky tap, or where the hose has been thrown down, are than those in other parts of the houses. Not only have the plants grown better, but they have given much finer clusters. Perhaps others who have been so unfortunate as to experience the disease will be able to say if they have made any observations with respect to water, whether for or against the theory here suggested. And if the explanation is wrong perhaps Mr. Abbey is capable of putting us right.

The point is a cultural one, as I have said, and it opens up the question whether the great majority of attacks, both of this and other diseases, may not be classed in the same category. When in Mr. Bunyard's nursery a few weeks ago I saw one of the best houses of Tomatoes I have ever seen, and his manager, Mr. Buss, expressed a strong opinion that good culture was equal to keeping away these insidious enemies. He maintains that diseases may be controlled with the watering pot and the ventilator, and fears none of them. Giving or withholding water and air are, he holds, at the bottom of them all, and with judicious management they may be circumvented. This is saying a great deal, and may perhaps be going too far for many people; but those who look below the surface will not be too hasty or too loud in their denunciations. Why does one person resist, and another succumb to, an infectious disease; or why, in one system, does a cancerous growth form and spread, while in another it is absent? It is in all probability from the same cause that some plants escape ravishing diseases while others fall a prey to them-namely, from the blood or sap, as the case may be, becoming morbid or impure. With pure air, adequate but not excessive moisture, and wholesome food, the stream of life flows with vitalising force, and the system is fortified against the mysterious agencies that hover unseen around and open to the unprotected the gate of death.—HYGIENIST.

HARDY FLOWER NOTES.

Still, as Allingham says, "Autumn's fire burns slowly through the woods," and they are aglow with the delightful tints of the dying leaves fast falling to join the bracken below, which, too, is bright with the colours with which it adoras itself ere its season is over. Yet to the gardener it seems as if he were standing betwixt the autumn and winter, and that the weeping clouds are mourning the bright days, and in their grief are striving to quench the thoughts with which the remaining flowers would cheer us. It is hard when drenching showers and chilly night air are our usual fare to drive away the pessimistic feelings all too surely pressing upon us. To the lover of flowers, however, pessimism is not a fitting mood. Passing clouds of sadness may dim the brightness of the sunny thoughts which find their way to his heart, but they are but fleeting, and ere long the visions of beauty which are ever present to his mind will exorcise the gloom, and he is free once more to feel, as Longfellow says, that

"For him the wind, ay, and the yellow leaves, Shall have a voice, and give him eloquent teachings."

While, as he commits to the soil the bulbs which another year will fill him with delight as he gazes upon their hues and forms, he has cause to look forward with hope. The present, too, affords much joy. The autumn Crocuses are full of chastest beauty as we look upon them in clumps in the borders or rockeries, or even when, as with the rarer kinds, only a few court the faint sunshine of October. The Michaelmas Daisies are beautiful as before, nay, shall we not say more delightful now, than when in the earlier months they had to rival the more gorgeous flowers of summer. The late sown annuals are still bright, and seem to say that they, too, are well entitled to at least a modicum of praise from our pen. The Godetias are still beautiful with their cups of ruby, of pink, or of delicate white, though they are dripping with wet, and though the welcome sun shines so faintly upon them. Sweetly comes the odour of the fragrant Mignonette from the borders, and the Asters with massive yet perfect blooms are beautiful. The Cornflowers of various colours, from brilliant blue to the soft white or the purple hued, have been of greatest value. But of these one might speak for long, and other flowers perhaps more seasonable would pass unnoticed.

Very charming is a clump of Crocus longiflorus, which has been striving unsheltered to face the furious showers which have come upon us of late. It cannot be said that it has escaped unhurt, but when planted thickly together these little Crocuses are better able to withstand the gales and rains of the autumn. Few there are who

fail to admire this exquisite plant with lilac flowers, with yellow throat and scarlet stigmas, and possessing the merit of being somewhat irregular in its flowering, some clumps giving flowers much later than others. Although a native of South Italy, Sicily and other parts in the same region, this Crocus appears to have proved perfectly hardy since its introduction in 1843. It is low in price, and is one which should be in every garden of hardy flowers. According to Mr. Maw's arrangement of the Croci, C. longiflorus belongs to Division I. or Involucrati—i.e., species with a basal spathe from the summit of the corm, and to Section II., Reticulati, "with a corm tunic of distinctly reticulated fibres." Very pretty also is C. medius, belonging to the same division and section, but having bright purple flowers veined in the inside with deeper purple, and with yellow anthers and scarlet stigmas. Not so showy as the Long-flowered Crocus, its colour is distinct, and its inclusion in the garden is to be desired.

Among the most graceful of the Coreopsis is the beautiful C. verticillata, the Whorled Tickseed, which has been in full beauty for a long time, and is extremely attractive with its finely divided leaves arranged in whorls, its furrowed stems, and its rich golden yellow flowers, not so large as those of some of the family, but still about 1½ inch across. It generally grows 2 feet in height, but varies according to the soil and treatment it receives. Introduced from the United States so long ago as 1780, it is somewhat surprising that it is still so seldom seen. C. verticillata appears to be synonymous with C. tenuifolia, although they are frequently

catalogued as distinct.

From the fact of its having received a first-class certificate when exhibited at the Fern and Begonia Conference of the Royal Horticultural Society in 1892, and having thus received what may be called the "hall-mark" among flowers, the flowering of Helenium autumnale striatum has been looked for with considerable interest in many gardens this year. There would appear to have been a great demand for this plant, and in all likelihood it has been extensively propagated, and the plants thus rendered temporarily weak. This, with the dry season, will account for the comparative disappointment felt at the appearance of the blooms when fully expanded. A well grown specimen planted in 1892, which I saw recently, was so good that one can fully recognise the merits of this addition to our autumn flowers, its orange and red flowers produced in great numbers rendering it very fine indeed. There appears, however, to be some confusion as to its nomenclature which it would be well to have corrected at as early a period as possible. When exhibited by Mr. T. S. Ware it was certificated under the name of H. grandicephalum striatum. In the Journal of Horticulture for September 22nd, 1892 (page 267) an excellent woodcut appeared, and in the notice of the plant the name is given as H. autumnale striatum. From a careful examination of the plant and comparison with a flower of H. grandicephalum which has reached me, I believe H. autumnale striatum to be the correct

Of Michaelmas Daisies there is no end, and from seed there is so much variation that to endeavour to clear up the nomenclature of the genus, or to speak correctly of them under name, would be a difficult and hopeless task. This, at all events, may be safely said, that we have too many to choose from, and that it would be well to see the plants in flower and select those which commended themselves to the intending purchaser. There are few which can well surpass the beautiful Aster amellus bessarabicus, of taller growth than the typical amellus, which, it may be, is the plant whose root Virgil in his fourth Georgic prescribes for sickly bees. Though we would gladly have this association wedded to the Bessarabian variety, its beauty in itself is a claim which admits of no denial, the fine large heads of deep purple flowers commanding admiration everywhere. Very fine also is one grown as A. spectabilis, which grows to about 2 feet in height, and has extremely deep coloured purple blue flowers, more starry, per-haps, than A. bessarabicus, but of much deeper colour. I must say, also, that I prefer the habit of A. bessarabicus, but A. spectabilis, which comes from North America, is good enough to be included in any garden. Of A. ericoides, the Heath-like Michaelmas Daisy, it may be said that few more pretty flowers adorn our gardens in September and October with its graceful foliage and white flowers in endless profusion. These and many other Michaelmas Daisies are of the greatest value in the garden of hardy flowers, and afford the highest pleasure to their owner.

The hardy Cyclamen still in flower reminds me that, having mentioned in some recent notes that C. gracum was in flower in my garden, an eminent authority on hardy flowers has in the kindest possible manner brought to my notice that what I had under this name was only a variety of C. hederæfolium, which is now recognised by botanists as C. neapolitanum. The latter species varies so much in foliage that it is difficult to recognise the various deviations as belonging to the same species, and as I had several

plants of the same character bearing the name of græcum and differing from all of a large number of C. hederæfolium or neapolitanum, I did not feel at liberty at the time to reject the name, especially in a genus so confused in nomenclature as the Cyclamens. It appears, however, that the true C. græcum is not known to be quite hardy in this country, and I am glad to have the opportunity of correcting an error easily made in connection with this difficult genus.—S. Arnott.

WINTER TREATMENT OF CANKER.

IMPROVING OLD FRUIT TREES.

Would Mr. Abbey kindly give some advice respecting the above?

I have recently succeeded to a garden where the fruit trees are all more or less cankered, and am very anxious to deal with the pest as promptly as possible. What means would he advise me to adopt between now and next spring? Obviously, these old trees cannot be cut down and thrown away, as young ones take time coming into bearing. Consequently it is of pressing necessity to attempt to deal with the canker, and if possible exterminate it. Of course I shall immediately cut out and burn all diseased branches that can be spared, but as many of the main stems and large limbs are affected remedial measures must be attempted.

Would, therefore, Mr. Abbey recommend paring and cutting away all diseased bark and wood, afterwards painting the wounds with neat petroleum, or, if that fungicide be too potent, with warm gas tar? So far as my experience goes, canker has a great dislike to

an application of hot gas tar.—INQUIRER.

[Although it is hardly possible to cure old trees of canker, much may be effected towards rendering them more satisfactory in their growth and crops by judiciously operating on their heads and supplying nourishment to their roots. The results in many cases exceed the expectations, so that trees that were doomed to be destroyed as soon as others could be grown to afford an adequate supply of fruit have become so profitable that their uprooting has been postponed indefinitely. Besides, the retention of old trees is in some cases an absolute necessity in order to have a supply of fruit, which, if not so good in quality or large in quantity as desired, is yet useful, and saves buying. The resolve, therefore, of "Inquirer" to make the most of his old trees, afflicted though they be with canker, until young ones planted in properly prepared ground arrive at a productive age, is a wise one, and worthy of adoption by others similarly circumstanced.

wise one, and worthy of adoption by others similarly circumstanced. The mode of procedure suggested by "Inquirer" is the correct one—that is, cut away all the dead and as much of the cankered parts as can be spared consistently with the prospects of productiveness. All such parts must be burned, not on ground occupied by the roots of the trees, but where the fire will do no harm, and the ashes resulting should be at once spread on the ground beneath the trees, and a foot further from the stem than the branches extend. This is one of the best possible manures for fruit trees, and restores to the soil, a small part it may be, yet some portion of the elements abstracted from it by the roots. Leached ashes—those washed by rain—have little manurial value; fresh ashes are a powerful

fertiliser.

"Inquirer" may then, as he proposes, cut away all the diseased bark, or such portions of it that is brown and dead, but it is not advisable to cut the wounds of old trees into the quick or live bark with the object of removing the mycelium of the fungus, if any, for the swellings in some cases almost encircle the limbs, and to cut these away entirely would be tantamount to ringing and killing the parts above them. The wood must not be interfered with, for it is unaffected by the fungus, and is necessary for the stability of the limb: After cutting away the diseased and dead bark, or so much of it as can be removed without damage to the live bark, dress the wounds with a solution of sulphate of copper, 4 ozs. dissolved in $6\frac{1}{4}$ gallons of water, applying with a brush, and well washing out the wounds, but without the liquid running down the stem. The wounds should be dry, and if fine weather follows, so much the better, as more copper will be absorbed by the bark and wood than if rains prevail. This will do much to arrest the growth of the mycelium of the fungus, and the tree will take advantage of it in the coming season to throw out more callus around the wounds, striving its utmost to cover them with new bark, which may be further accelerated by plastering the wounds with a mixture of clay and fresh cow manure.

In addition to the pruning, trimming, and dressing the wounds and cankerous parts, "Inquirer" may uproot perennial weeds and burn them, turn the ground over without disturbing the roots more than can be helped, yet burying soft weeds that will decay. This should be done as soon as the leaves fall, and the pruning, trimming, and dressing of the trees completed. Then apply the following mixture:—Steamed bonemeal and kainit in equal parts, mixed, spreading it evenly from the stem outwards to a foot beyond the

spread of the branches, at the rate of $3\frac{1}{2}$ lbs. per rod, and as the surface is loose it may be left for the rains to wash in. But if the soil and subsoil be dry, make holes with a crowbar, and fill them with water time after time, following with liquid manure, then fill the holes with fresh soil pressed firmly down.

Before the buds commence swelling in the spring, spray the trees when they are dry with a solution of sulphate of copper, 1 lb. to 25 gallons of water, using the knapsack pump "Eclair." This should be followed by a dressing of nitrate of soda to the soil when the trees are starting into growth, using $1\frac{1}{2}$ lb. per rod if the ground be naturally moist, or 2 lbs. if inclined towards dryness, applying it from the stems to a foot beyond the spread of the branches.

This is the whole of the prescriptions I advise "Inquirer" tofollow, except if the soil requires draining it must be attended to first thing, for no fruit tree can thrive in a badly sanitated soil. The prescriptions will be as useful in subsequent years as at present, only they must be used according to circumstances, and in a less.

drastic manner.

I strongly advise "Inquirer" to have nothing to do with petroleum, and still more so as regards gas tar. Both are strong, yet dangerous medicines, for though they destroy many insectal and fungal germs and pests, they may also kill the patients, if not cripple them for life. I have a strong objection to all oils and fats for applying to the stems and branches of fruit trees on account of their slow but certain reactions, and even when saponified, as in soft and hard soap, there is danger in using them at great strength, say 8 ozs. of softsoap to a gallon of water, as is often recommended for dressing Vines, and the result is they break badly in consequence. Gas tar is still worse, and often enters into the composition of cart grease to such an extent as to kill the stems of trees to which it is applied to prevent the ascent of wingless moths and beetles.—G. Abber]

CATTLEYA BLESENSIS.

When exhibited on the occasion of the meeting of the Royal Horticultural Society at the Drill Hall, Westminster, on September 26th, by Messrs. B. S. Williams & Son, this pretty Orchid attracted attention. It is the result of a cross between Cattleya Loddigesi and Lælia pumila. The flowers are of a mauve shade, but the lip is richly coloured with purplish magenta. Judging by the plant exhibited the pseudo-bulbs are of a slender growth, nearly a foot in length, and each bears two bright green leaves. As already reported in this Journal an award of merit was adjudged for this interesting hybrid.—C.

STENOGLOTTIS LONGIFOLIA.

This is a comparatively recent introduction, and as yet is scarcely known in gardens. It was sent to Kew by Mr. Medley Wood, Curator of the Durban Botanic Gardens, Natal, and flowered for the first time in England in 1889. Previous to this Stenoglottis was regarded as a monotypic genus consisting solely of S. fimbriata, a pretty little terrestrial Orchid not uncommon in gardens. S. longifolia does not differ very materially from S. fimbriata in general appearance, but is a much larger and finer plant. The chief distinction between them, apart from the difference in size, is in the leaves. S. fimbriata has short oblong leaves, freely blotched with black, while the leaves of S. longifolia are longer, ensiform, and lack the blotches. The flower-scape is erect, about 15 to 18 inches high, and the upper half is densely clothed with small, deep mauve flowers with fimbriated lip.

flowers with fimbriated lip.

S. longifolia and S. fimbriata are both natives of S. Africa.

They require a cool or intermediate temperature, and should be potted in a mixture of loam, leaf soil, and sand. Abundance of water during the growing season is essential.—A. B.

CYPRIPEDIUM EURYANDRUM.

This is a handsome and distinct hybrid Orchid that has been in cultivation for many years. It was raised by Mr. Seden, of Messrs. J. Veitch & Sons, I believe, from crossing the free-flowering and useful species Cypripedium barbatum with pollen from the beautiful C. Stonei. The result was a form quite intermediate in character between the two species, and possessing a large share of the attractions of each. The hybridity is especially

noticeable in the petals, which, though considerably longer than those of C. barbatum, are yet proportionately shorter than those of C. Stonei, and the colouring is shared in an equal degree. The labellum has a near resemblance to that of C. barbatum, but differs in the greater size it attains. The obtuse upper sepal—tinged with crimson, striped with green and black—also imparts a very distinct attractive appearance to the flower. The petals are fringed with hairs, and bear on the upper surface numerous peculiar wart-like protuberances, while the labellum is dark-coloured, crimson and brown shades being combined. The foliage is also handsome, being of rich deep green, in which an approach to tessellating is faintly visible, and the plant is of vigorous habit, flowering freely, with similar treatment to that required by other Cypripediums.—Specialist.

THE PRINCIPLES OF HEATING:

INCLUDING THE ARRANGEMENT OF HOT-WATER PIPES FOR (a) FRUIT HOUSES;
(b) FORCE G HOUNES WITH BOTTOM HEAT; (c) BEST KINDS OF FUEL, WITH
THE MANAGEMENT OF FIRES, AND THE REGULATION OF TEMPERATURES.

Silver Medal Essay by Mr. HARRY CORLETT, Foreman, Woolton Wood Gardens, Liverpool.

INTRODUCTION.—This subject covers a very large area, and it is one which, I am sorry to say, that many gardeners know too little about. It seems quite sufficient for some of them to know that a house, or a range of houses, has been erected and fitted with hot-water apparatus by a horticultural builder; and, although the work done may be satisfactory to the builder, yet it does not always meet with the requirements of the gardener, and as he is the person who, very often, has to earn his livelihood by the products grown in the houses, the necessity of having some knowledge of the principles of heating at once presents itself to him. I trust the day is not far distant when young gardeners will be taught a thorough knowledge of heating, in a similar manner to what they are now taught when they should water a plant, because I consider one quite as necessary as the other from a practical point of view. When this becomes part of their education we shall then hear of less damage being done to boilers, pipes, and plants. I will treat the subject from a scientific point, yet making it plain and practical, with tables and diagrams attached, for the benefit of those who may require its assistance, making link by link, as it were, thus forming a chain of information which should be in the possession of everyone who works in, or receives any benefit from, an horticultural structure heated by hot water.

This paper must be divided into eight distinct parts — viz., (1) Principles of heat, because we must first learn how, and why, hot water heats a house; (2) Houses with their various positions, plants, and temperatures; (3) The thermometer, to ascertain the different temperatures; (4) Pipes to secure the various temperatures; (5) Boiler to heat the water in the pipes; (6) Fuel to heat the water in the

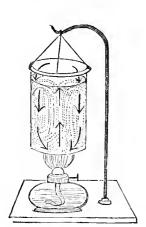

FIG. 47.

boiler; (7) The stoker to work the fuel; (8) The duties of the stoker. Each part being individually treated, and, as one is, practically speaking, of no use without the other, they must be all linked together to obtain a final and satisfactory result.

(1), HEAT AND ITS TRANSMISSION.

A body or substance becomes heated when brought in contact with or placed under the influence of any other body or substance hotter than itself, the colder body receiving the heat by either of three modes, viz., convection, radiation, or conduction.

In the "convection" mode the smallest parts of the body nearest the heat are the first warmed, and these when heated begin to move

throughout the body, their place always being taken by the colder parts, and the motions thus started are called convection currents. A very simple and interesting example of this is to take an ordinary glass (fig. 47), nearly fill with clean cold water, place a spirit lamp under the bottom of the glass, and then watch the results. The particles of water first heated begin to rise in a direct line from the lamp flame to the top of the water. The colder particles of water from around the sides of the glass, being heavier than the heated particles, at once begin to descend, and thus two currents are formed, the direction of which can be made more apparent by adding a little fine sawdust to the water previous to putting the lamp under the glass. This example shows that convection currents carry the

heated parts of a body away from and bring the colder parts nearer to the source of heat.

In the case of "radiation" the mode of transmission is different to either of the others, the heat being carried through a material medium. Take an example. Expose a piece of steel to the direct rays of the sun; its temperature soon begins to rise from its original point, whilst the atmosphere around it is scarcely changed, thus showing that one body may be heated by another body, yet the space between the two will not be noticeably changed in temperature.*

By "conduction" we have yet another mode of transmitting the heat from one body to another, for a body heated by conduction always moves in the direction where the temperature is colder, and each particle of the body, as it moves through the mass, is slightly robbed of its heat by neighbouring particles. The heat by which the water in a kettle is boiled is transmitted from the coals through the bottom of the kettle by conduction.

The three examples given will show the principles by which our houses are heated. First the heat passes from the furnace through the boiler plates to the water in the boiler by conduction. It is then transmitted through the mass of water into the pipes by convection, and from the pipes to the air in the houses by radiation, and the atmosphere thus warmed is then at our disposal.*

(2), Houses, their Positions, Plants, and Temperatures.

Assuming there is a particular piece of ground allotted, upon which a certain number of houses have to be erected, I have drawn a ground plan as a guide, this, I think, being the most systematic way of laying a foundation to work upon. The dimensions are given in each case, which can either be enlarged or reduced to suit various circumstances.

As will be seen by the plan (fig. 48) there is a wall running north to south on one side, and a wall running east to west on the other side. The two remaining sides are hedges. Along the wall running east to west are placed the early, medium, and late vineries, early Peach house, and propagating Pine house, all of which are three-quarter span-roofed. The wall running north to south is occupied by a late lean-to Peach house, while the remainder of the ground between the late Peach house and the opposite hedge is utilised by three Melon houses, one Cucumber house, two forcing houses, and one fruiting Pine stove, all of which are span-roofed. If two forcing houses are not required then J can be substituted by L, and an orchard house M would occupy the position of L. On the plan will be found the exact position of the houses, boiler, sheds, Mushroom house, office, the direction of the hot-water pipes; also showing how, by the assistance of valves, each house can be individually heated without affecting any of its neighbours. The pipes will perhaps be shown more clearly in the section (to follow)...

VINERIES.—The early house should be started in December at a temperature of 45° at night, allowing a rise of 5° during the day. The heat should be gradually raised until it reaches a night temperature of 65°, and by this time the Vines will be in flower, when the heat must be decreased to 60° until the stoning period is over; then further increase it to 65° night. This temperature may be continued until the Grapes are ripe, which will be about the middle of May. After the fruit is cut admit abundance of air to ripen the wood.

The second, or medium vinery, must be started about the end of February at a night temperature of 45°. The various temperatures of the early house will answer admirably for this structure excepting when occupied by Muscats; then an addition of 5° throughout will be necessary. The fruit in this house will be ready to cut about the middle of July.

The Vines in the late house will start about the beginning of April, when the night temperature must be kept about 50°, and as the season advances and the growth makes headway the night temperature should be raised to 60°, with 70° during the day, allowing a rise of 10° by sun heat. The fruit in this house will be ripe by September, thus maintaining a supply of Grapes from May until January.

PEACHES AND NECTARINES.—The early Peach house may be started in January at a night temperature of 45° to 50°, gradually raising the temperature to 55° about this time, when the trees will be in flower. After the flowers have set again increase the heat until it finally reaches a night temperature of 60°, always taking advantage of sun heat by closing the house early, and by so doing raising the temperature to 75°, which will be found very beneficial to both growth and fruit. Under such conditions the latter will be fit for the table by the middle of May.

The late house will naturally start of itself about the end of

^{*} R. W. Stewart, B.Sc., Lond., "Text Book of Heat," chap. x., pp. 191, 192. Published by W. B. Olive & Co., 13, Booksellers' Row, Strand, W.C.

February, when a night temperature of 45° will be required. This temperature should be gradually raised as the season advances; the night temperature never exceeding that of 60°, so that very little fire heat will be necessary to produce ripe fruit by the end of June, when the trees in the orchard house or those grown on a south wall will afford a succession.

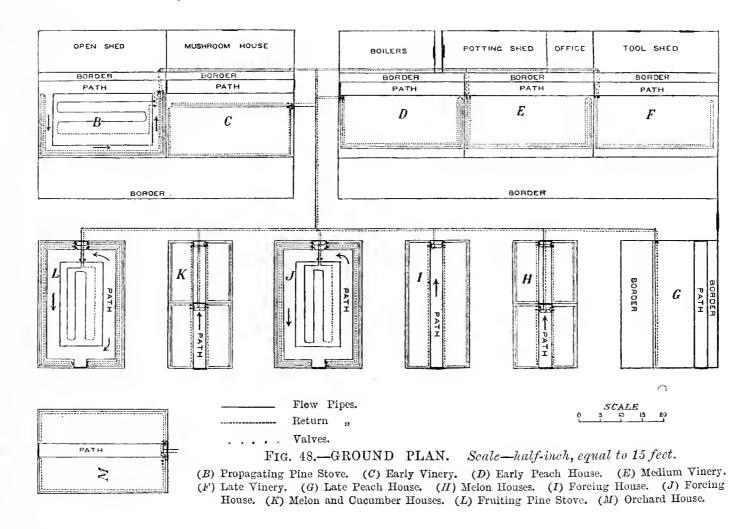

MELONS.—The first Melon seed should be sown early in January in a temperature of 60° at night and 65° by day. This will be found high enough for seedlings at that time of the year. After they are finally planted raise the temperature to 70° at night, while that of the bed must not exceed 80°. In this temperature the fruit should reach maturity by the end of April.

For the second house crop the seed must be sown in the middle of February in a temperature of 65° night. After the young plants are transferred to the bed afford a rise of 5°, allowing the temperature to increase to 80°, or 85° sun heat. This crop will be ripe early in June.

Seed for the third house should be sown by the end of March in a heat of 70° night. The temperatures given for the second house will

of 75° to 80°, with a night temperature of 65°, that of the bed being a steady heat of 85°. In this temperature the young suckers or crowns will readily root, and as they grow and the winter approaches the tempe rature may be reduced to 55° night, 60° day, and that of the bed 75°. The largest plants in the bed should be grown at one end so that they may be used as succession plants. The fruiting house will be occupied by a selection from the succession plants, and they will require a night temperature of 60° to 65° for winter. As the flowering period arrives increase the night heat to 70°, and the day temperature 75° to 80°, a dry atmosphere being necessary at this time, and again when the fruits show colour a similar atmosphere will be essential, including the admission of a little air night and day.

ORCHARD HOUSE.—Here we have a structure which can be used for the purpose of securing early fruits of Plums, Apples, Pears, Apricots, Cherries, &c.; also late crops of Peaches, Nectarines, and Strawberries, the Strawberries having been forced on shelves in the early vineries or Pine stove. The two great essentials in an orchard house are abundance of light and air. Artificial heat will not be in much demand, as a night

also suit this house, and the fruit will ripen about the middle of July. After this house is cleared of its fruit it may be utilised by having late Tomatoes, which would yield a good crop if grown in a dry, cool atmosphere, and as the winter approaches, the minimum temperature being 55°.

CUCUMBERS.—This one house will be found ample, by alternately planting each side of the house. By sowing seed in September, and keeping a moist atmosphere of 65° night, while that of the bed is 75°, Cucumbers will be ready for cutting by Christmas. If seed be sown at intervals of six weeks there will always be a number of young plants ready to take the place of the older ones, thus ensuring a regular supply throughout the year.

Forcing.—These houses are used for compelling plants to bloom at unnatural seasons. If there are two houses at our command, one should be kept from 60° to 65°, and the other 70° to 75° night, because the majority of plants yield the best results when placed in a mild temperature until the buds have swollen, and then placed in the stronger heat of the warmer house. As a general rule, plants subjected to too much heat at first often drop their buds, and thereby frustrate the object in view. Although the plants will be forced principally by artificial heat, yet advantage should be taken of all sunshine procurable, when the temperature may be allowed to rise 10° or 15°, which will greatly benefit the occupants of the houses. One end of the coolest house may be used for the cultivation of Figs.

PINES.—The propagating house will require a summer temperature

temperature of 45° will be all that is needed, and even this can be dispensed with when the weather is not severe; but should the weather prove dull and wet during the flowering period, a little fire heat would be advisable to insure a good setting of fruit.

(To be continued.)

OUT OF TOWN.

WET and shivering, with almost a chattering of teeth, was the condition of the quixotic "foresters" on arriving at the longed for destination on one of the rare, cold, rainy nights of the passing away summer; but all temporary discomforts quickly vanished on entering the cheery home of Mr. Merryweather-a home of sweet flowers, Even such whitewarm welcomes, good fare, and bright music. bearded and silvery headed ancients that hobbled about after frisky Fenn at Sulhampstead not long ago must soon forget past shiverings under a change so pleasant. What wonder, then, that the younger and buoyant spirits which emerged from the wild forest should resume their wonted gaiety at once when brought back to the luxuries of civilisation? What! Mr. Merryweather young; he who has grown-up sons who stage Roses so well at the shows! Surely No, he is as fresh his locks must be "silvered with past years." and active as they, and can share in the refined pleasures of life with equal zest, and is just as quickly, keenly, critical as they are over They are like the merits and defects of the last new Rose. brothers, are these two generations of Merryweathers, in their pleasant home at verdant Southwell: and to hear them talk about Roses as if no one was there is a treat.

"We could have staged grandly to-day, couldn't we, Harry? Did you ever see such a Pig? and then that Duff, it was wonderful, wasn't it? Yes; and Dick was lovely, wasn't she?" and so on through an ideal forty-eight that "Ned" was enumerating to his brother, but all for the ear of Henry, the head, who would keep suggesting faults in this Rose and that. "Ah, but you should have seen the blooms," rejoined the youngster. "You don't know what you have missed. We could have run Cant hard to-day; pity there wasn't a show before the rain spoilt 'em," and so on. This perversity of Roses in opening between the shows appears to be chronic and incurable. It seems to display itself everywhere; and the references to varieties by workers among them, and who become familiar with them, are somewhat puzzling to an outsider. Fancy the bold liberty in calling the Marchioness of Dufferin, "Duff;" Margaret Dickson, "Dick;" and Gustave Piganeau, "Pig," and all in the way of endearment, too! Is it not peculiar? But they will do it will these earnest men, who spend their lives among Roses, and talk to each other about them.

them.

"You have done pretty well at the shows this year—blooms rather small perhaps, but fresh and bright," observed he of the city; "but don't you think you want a little more size?" "Well," said the youthful senior, "we can get colour here, there is no doubt about that; and give me good form, brilliancy, and freshness, and they can take the dingy big 'uns. But all the same, we mean to have more size; bought a fine piece of land 4 or 5 feet deep of sound loam. You must see it." "Another piece! Then how much land have you now?" "Sixty-five acres." Thus has the once little nursery grown, the result of sound knowledge, good judgment, cultural skill, diligent work, and business enterprise—just the qualities that have made many a once-small local nursery famed throughout the land, in the case under notice the growth being mainly stimulated by "Bramley's and Roses."

"And how are the Bramley's this year?" "Oh, they are all right. You must see them." "And what do you think of the newer Roses?" "Well, some are good; we must look at them in the morning. The host appeared to be getting uneasy; in fact, he was under "influence," for his clever daughter was presiding at the piano in the drawing-room, and sundry friends were singing. He could endure our prosy talk no longer, and cut it short with a "Come, now, let us stop this, and have some music." "What, music after midnight! It's bedtime." "Bed or no bed, we must have music. I have a few friends in the house, one or two local celebrities, and we have to hear them." Open flew the doors, and there was a general movement of happy humanity. "Ah, Herr Jumpi, allow me to introduce you, also Signor Ponderoso, to my friend, Mr. Cityman." Then the concert began, and after it ended we had not long to wait before it was time to be out and among the Roses.

No doubt the rain had done something to freshen vegetation, but it could not have transformed the burnt up pastures of the south into a mass of green verdure in a night. Refreshing green was everywhere around—on banks, lawns, hedges, and fields. Flowers were flourishing as if there had been no drought. Masses of Delphinums 8 feet high, golden pillars of the stately Verbascum olympicum still higher, the pure white bell-shaped Campanula persicifolia grandiflora, one of the finest of the family, with most of the best hardy border flowers in season. On the rockery glittering golden sheets of Genista tinctoria flora-pleno, in contrast with dwarf Campanulas of the beautiful turbinata group in various tints, and Tropæolum polyphyllum trailing over the ground densely laden with its yellow flowers—all these and others told us there had been no such drought exhaustion as had to be endured by flowers and their cultivators in the south. No doubt the soil in the valley of this fertile district of Nottinghamshire is naturally rich, deep, and retentive; but it was hard to think there had been "no rain worth mentioning" for several weeks. Yet go where one might an idea seemed to prevail that the brunt of the heat and drought was borne by that self-same place, no matter how green the fields and bright and fresh the gardens. True, the sun brought out the Roses too quickly-did not give them time to "fill up," but all the same, broadly and generally speaking, the land has been a veritable Land of Goshen in the north this year in comparison with the Sahara-like aspect of country along the south-east coast, though rich soil and deep culture have told there like oases in the desert; but we are scanning the Roses at Southwell, noting more particularly the newer varieties that had flourished the best under the burning sun of 1893.

Amongst Hybrid Perpetuals the following were giving satisfaction:—Bruce Findlay, regarded as a valuable addition to the

very bright red Roses, particularly free and attractive in colour; Danmark, very fine indeed, after the style of La France, but more globular, the petals thicker and thus more lasting than the old favourite named; Duchess of Albany, another of the La France family, but deeper in colour, in other respects identical with its parent; Gustave Piganeau, one of the finest of the newer Roses, has flowered as well this dry season as during the wet period of last year, plants dwarf in habit, hardy, and floriferous; Germaine Caillot, a flesh-coloured variety, flowered well this season; Jeannie Dickson, rosy pink with paler margins, one of the most useful of the Irish raised Roses; La France de 1889, a fine large-petalled Rose of pleasing red colour; Marchioness of Dufferin, a very full Rose of a peculiar shade of pink, attractive when young, but inclined to coarseness; Margaret Dickson, a beautiful fleshy white Rose, evidently liking a hot season, being so much better than last year, and very vigorous.

Amongst Teas Ernest Metz is regarded as one of the best pink varieties of recent years, the stiff flowerstalk holding the blooms erect; and Waban is looked upon as a distinct form of Catherine Mermet, being darker in colour. The Hybrid Tea Gustave Regis is charming when the swelling buds show their clear canary yellow colour, tinted darker on the edge, and the variety is expected to be a favourite for buttonholes, sprays, and allied forms of decoration; and the Bourbon Mrs. Paul is a great favourite, flowers a pleasing blush white, and plants robust in growth. Those were the most prominent moderns; but no one could see the floriferous masses of the charming Polyantha Roses without admiring them, Madame A. M. de Montravel, Etoile d'Or, Golden Fairy, George Pernet, Little Dot, Perle d'Or, and The Pet appearing as if each were trying to outrival the other in productiveness and chaste beauty. Southwell has evidently a good Rose soil, and the collection of We must, however, leave the Roses varieties is very complete. and glance at the fruits.

Every Apple-loving visitor to Southwell is bound to notice Bramley's Seedling, for the simple reason that he cannot help it. Large old standard trees here and there excelling all others in their loads of fine fouit; young orchards in fine bearing condition—trees which, if practically let alone, open themselves out naturally and prevent overcrowding, and a forest of young stock standards and dwarfs, distinct by their sturdy vigour and robust leafage. "Merryweather has Bramley on the brain" once observed a brother in the craft. Yes, he has; and will keep it there. It makes no difference to him whether he sells 20,000 trees of it or of other varieties, but he likes to see his favourite go, as he is convinced that it will do him more credit than will several others, against which he has nothing to say; but his faith is unshaken in his protégée, indeed it seems to increase with experience. "Look at the trees," say, as he points to their dark green heads and fine fruit shining on the branches; "then look at others around them. Doesn't it speak for itself? I tell you Bramley's is a topper—never anything the matter with it; fights his way through everything—frost or heat or canker, and the fruit is always wanted in March." Then he goes on to say, "And I will tell you another good Apple-Lane's. Yes, if I were planting for money-making my two chief Apples would be Lane's Prince Albert as dwarfs, with Bramley's in that form, and as standards. Lane's will bear tremendously and soon pay, but cannot wear like Bramley's. Find a better pair if you can for planting by the dozen or the hundred. I cannot, and I think I have all the best sorts in cultivation." As early Apples the two Southwell favourites are Domino, one of the best of growers and bearers, in demand not only for new plantations but for filling vacancies in existing orchards; and Russian (Duchess of Oldenburg) hardy, early, a free grower and bearer of attractive and refreshing fruit.

For grafting old trees—putting new and fruitful heads on old trunks—Bramley's, by its inherent vigour, excels all others, but Mr. Merryweather's method of grafting old trees differs from the usual procedure of cutting the main branches down to within 6 or 8 inches of the trunk. He simply saws through the stem below the branches, pares the top smooth, and inserts scions an inch or two apart all round between the bark and the wood. Even if the trunk is cankered new matter is deposited by the young and vigorous growth, and thus the faulty old stem is encased in new wood. The strong growths also, as must be the case, promote corresponding root extension, and previously worthless old trees are transformed into bearers of excellent fruit.

I cannot go into other kinds of fruits, except to say that Plums are grown extensively in Nottinghamshire, Victoria being the favourite, a purple local variety known as Johnny Raw being also in demand. As an early dessert Plum of the first quality Mr. Merryweather says Early Transparent Gage should be grown in every garden in the land, and perhaps its raiser, Mr. Rivers, will agree with him. But there must be an end of writing, and so, as

our American cousins say, I stop "right here," and begin to pack up for home.

"No you don't," sounded an imperative voice, "there is to be a meeting to-night of the Gardeners' Society, and all the best men will be there." This implied that in the opinion of the speaker gardeners are the best men around Southwell. Well, the meeting was a good meeting of good men, and Mr. Merryweather delivered a good lecture on fruit growing generally, and the capacity of the district for sharing more largely in the general supply of high class produce. Your correspondent ventured modestly to suggest that the lecturer was right, then hastened away, as he began to feel his "out of town" exercise rather trying, and was glad to get to London for quietness and rest.—A CITY MAN.

NATIONAL ROSE SOCIETY-MR. MAWLEY'S ANALYSIS.

THE analysis of the Rose seasons of 1886-1893 by Mr. Mawley (page 303) is very interesting and of great service to exhibitors; but I should like to call attention to some of his deductions, which, I think, are partly based on erroneous premises and incorrect arithmetical calculations. Mr. Mawley compares the Crystal Palace Rose Show of the N.R S. in 1893 with that of the same Society in 1879. Although a member of the National at the time I have no recollection of the Show of 1879, but I think for a fair comparison of the two years it would be also desirable and necessary to have the comparative number of members and the number of classes open to exhibitors in each year. These I cannot give, not having a report for 1879; but the members' subscriptions to the Society in that year were £217, and for the current year should be at least £380. Last year they were £368, and I am aware of a considerable addition to the roll of subscribers since the last balance-sheet was published. Another point also to be fully con-idered is the enormous strides taken in horticultural affairs and increased interest in Rose growing since 1879. If, for instance, one only went back even five years and compared the position of the R.H.S. (the lealing Society of horticulture) and its list of members in 1887 with its roll now, it would show how this interest has increased. These facts all taken together prove that a bad Show in 1893 is a much more important item than an indifferent one in 1879, a date at which the strong revival in flower culture was really only in its initial stage, and I therefore take exception to the statement that visitors and exhibitors should as a matter of course expect bad Shows in a season—a glorious season, too, in many respects!—like that of 1893. The remedies are numerous and obvious, and there were splendid R ses seen this year at other places, notably on the 24th June at Reigate, although there were not many instances of good flowers at the Crystal Palace on the 1st July; but as long as our Society is bound down by hard and fast rules, and, so to speak, tied to the Crys'al Palace, so long shall we be subject to the caprice of fortune in regard to the weather at the date to which we are fixed six months in

In going into the analysis, of the average number of times certain Roses have been shown, Mr. Mawley has made a serious error in regard to Gustave Piganeau. Last year, as he himself states, it was forty-sixth and shown eight times; he now says, "at one bound" it has leaped to No. 8. But it has done nothing of the kind. It was as I say shown in eight boxes last year and in twenty-four boxes this year, so that according to arithmetical average it has been shown sixteen times, and should be bracketed as twenty-third and not eighth. I should also like to know in how many of the professional and big amateur boxes it was shown, as I should think that the twenty-four exhibits came almost entirely from these sections.

I also find that Ernest Metz should not come in the Tea Rose analysis at No. 7, but bracketed at No. 15 with "Madame Hoste," as the average for 1892.3 is 21—viz., 12 + 30. My view of Ernest Metz is quite in agreement with that recently expressed in your Journal by Mr. D'Ombrain (page 201). The Rose is apportally a great pet of some of the professionals, although, strange to say, they have not higher the professionals, although, strange to say, they have not hitherto shown it to great advantage or to any extent in the N.R.S. class specially set apart for it at our metropolitan meeting.

There is no doubt, and in this I entirely agree with Mr. Mawley, and have elsewhere stated so, that Horace Vernet and Mrs John Laing have been most satisfactory Roses to many exhibitors this year. I do not suppose Horace Vernet has ever been so frequently and so splendidly staged as it has been in 1893, and the flower which won the N.R.S. medal at the Crystal Palace for Messrs. Harkness was probably the finest specimen shown during the year.

I am surprised that Mr. Mawley has not named Mr. B. R. Cant's Prince Arthur amongst the H.P.'s which have been a great success this season. It has seldom been seen to greater advantage, and with Roses such as Duchess of Bedford and Earl of Dufferin as well as Horace

Vernet (which three are difficult of culture) shared the honours amongst the deep reds.

In reference to what Mr. Mawley says about the peculiarity of the season in certain varieties and his deductions therefrom, I should not describe Dupuy Jamain or Duke of Wellington as late-flowering varieties in any year, nor would I class La France merely as an early bloomer, but as a true perpetual, flowering early and late; and as to A. K. Williams, I may mention that in the N.R.S. new catalogue that Rose is specially described (why, I cannot tell) as "good in autumn." A. K. Williams is always good, but it is better in the summer than autumn with most people.

I am very pleased to see that Mr. Mawley has at last brought the beautiful Rose Ethel Brownlow into his analysis, and literally and truly "at a bound" it takes the position of No. 20. If that position were on the year's exhibits Ethel Brownlow would be No. 14. There is no Rose which excels it in beauty of form and colour, and its rival in these qualities I consider to be Comtesse de Nadaillae, which in 1893 has been the Tea Rose most frequently shown, the hot weather suiting it to perfection.—CHARLES J. GRAHAME, Croydon.

EVERY Rose lover will unite in tendering hearty thanks to "E. M." and those who assisted him for the interesting analysis of our favourite flower in the last issue. Personally I have never felt that this was the best way of arriving at, say the best twenty or thirty Roses for an intending aspirant for Rose fame to select; but it is none the less interesting on that account. I have always thought that it showed rather the Roses that stood best the test of certain seasons; this has been particularly brought out in the present analysis. I fancy that any exhibitor would prefer Ulrich Brunner to Marie Baumann, and yet the average is nearly four higher in the former. Only our old departed friend "Rushton" Radcliffe, I think, would agree with this, and he never could forgive her modest behaviour in hanging down her head, and on this account would never place her amongst the first forty-eight!

Then a season that is inimical to a certain Rosc has an effect of a very damaging character on its position for many years. La France, fo instance, has disagreed with this dry season, or vice versa. Although it often refuses to unfold in wet weather, certain it is that in the early and in the thickest portion of the exhibition season the specimens of La France were not only few and far between, but they were also mediocre in character. Marquise de Castellane being one of the earliest in bloom, I suppose had retired from the fray before the National; whilst Marie Finger with me declined to exhibit her charms till late, but then I thought her finer than usual. Gustave Piganeau is a great acquisition. It may not be a very good grower, yet it gives many blooms and these decidedly large, and it is in my experience one of the very best autumn bloomers. I should think this will be considered the Mrs. John Laing year, and it is one of the brightest gems in the Rose crown of my old friend who was too early taken from us, the late Mr. Henry Bennett. A curious circumstance connected with this Rose and showing how much it enjoyed the past season was the fact that at one of the West of England Exhibitions (Bath, I think) in the class for any variety of Rose, twelve blooms, there were five stands, and every one of them was Mrs. J. Laing. I looked down the list to find Augustine Guinosseau. Though so similar except in its colour to La France, with me it has this season given more beautiful flowers than La France, and yet my plants of the latter are as four to one. I am disappointed to see her only conspicuous by her absence.

In the Tea classes Catherine Mermet will always be hard to beat. Her sports will probably be her most dangerous competitors, but it must not be forgotten that by the date of the National Exhibition the great beauty of its most dangerous rival, Maréchal Niel, is a glory of the past. I apprehend very few exhibitors would place Maréchal Niel at its best at No. 9. In form, substance, and colour it is the equal of Catherine Mermet, whilst in size it surpasses her without the shade of coarseness which size sometimes brings with it. Maréchal Niel requires a sort of protection when grown in the open; its weight makes it a hanging flower, and the peculiar formation of the seed vessel is provocative of decay in wet weather. The stem is inserted into a hollow as it were, and in dripping times this hollow is generally full of water, and this proves, in my experience, a fertile source of decaying blooms. Hence, were I growing Marechal Niel against an outside wall I should always endeavour to give a foot of shading at the least overhead. The sports of Catherine Mermet seem to follow the good example set by the parent. The Bride and now Ernest Metz are splendid Roses. Will Waban, another of the tribe add to the éclat of the parent? I have only seen it on starved plants, and therefore hard to judge; but form, substance, and colour are there, and I think it must soon be found in the analysis.

"E. M." (page 303) will forgive my suggesting the date of Cleopatra as too recent. This must be the case unless my friend Mr. H. Bennett sent me a plant before he put it into commerce, as, unless I make a great mist..ke, it was in 1888 when he sent it to me. It is certain to rise above its present position. "E. M." has this year, I think, added very much to the value of the analysis by giving, for the benefit of beginners, a select list of good varieties. To this list few will take exception; but they may wonder with me why, in the face of the analysis, Catherine Mermet, Comtesse de Nadaillac, and The Bride are omitted from the Tea list! Still, thanks many to "E. M." and his

helpers.—Y. B. A. Z.

THE WEATHER IN LONDON. — Since publishing our last issue much rain has fallen in the metropolis. On Friday evening it rained heavily for several hours, as it likewise did late on Saturday. Sunday was fine, the same applying to Monday, but an inch of rain fell on the evening of the latter day in some localities. Tuesday night was wet, and Wednesday opened similarly, the rain continuing throughout the day.

— THE WEATHER IN SCOTLAND.—Mr. G. McDougall, Ravenna Cottage, Stirling, writes:—Rain fell here in September on twenty-two days. The greatest amount in any one day was 0.385 inch, on the 29th. Total for the month, 1.447 inch. Warmest day the 2nd, with 793° maximum and 55° minimum. Coldest day the 21st, with 49·1° maximum and 33° minimum. Frost occurred on three nights, 10th, 12th, 11th severest, 30·8°. Mean maxima 63·2°, mean minima 43·6.

— COMPLIMENTARY DINNER TO MR. H. TURNER.—On Monday evening last Mr. Harry Turner, of Slough, was entertained at dinner by a number of friends at the Gardening and Forestry Exhibition, Earl's Court, in recognition of his services as president of the horticultural section of the Exhibition. Mr. Milner, F.L.S., C.E., presided, and warmly eulogised Mr. Turner's services in organising the numerous floral exhibitions that have been held during the season and in the decoration of the gardens. A handsome epergne was presented to Mr. Turner as a memento of the occasion,

— The Royal Gardeners' Orphan Fund.—Intending subscribers are respectfully reminded that the collecting cards recently issued amongst the gardeners and general nursery trade throughout the country should be returned during the course of the ensuing month. It may be stated again that every 5s. collected will secure a vote for the next election, and every £5 a vote for life. It is earnestly hoped a very liberal response may be made to this appeal in order to meet the requirements of the present year. Collecting cards may still be obtained on application to the Secretary or any member of the Committee.—A. F. Barron, Hon. Sec., Royal Horticultural Gardens, Chiswick.

- HELP FOR GARDENERS' ORPHANS.—A grand evening concert will be given at the Assembly Rooms, Surbiton, on Wednesday evening, October 25th, 1893, in aid of the Royal Gardeners' Orphan Fund. Among other distinguished patrons of the concert are the Mayor and Mayoress of Kingston, the Recorder (C. W. Bardswell, Esq., J.P.), Sir Douglas Fox, J.P., and Lady Fox, J. P. Trew, Esq., Mrs. Shrubsole, W. A. Bevan, Esq., and Mrs. Bevan, H. K. Studd, Esq., Mrs. Nops, G. C. Sherrard, Esq., J.P., and Mrs. Sherrard, H. C. Paice, Esq., and Mrs. Paice, E. T. Coppinger, Esq., and Mrs. Coppinger, W. Furze, Esq., and Mrs. Furze, and Ernest V. Douet, Esq. The concert will commence at 8 P.M. Carriages at 10.15. The prices for admission are—Stalls, 5s.; numbered reserved seats, 3s.; centre seats, 2s.; back seats, 1s. An excellent programme has been arranged, and tickets may be obtained of Messrs. Bull & Son, Victoria Road, Surbiton; Mr. W. Drewett, Market Place, Kingston; of any member of the Committee; and of the Secretary, Mr. A. Dean, 62, Richmond Road, Kingston.

—— Potatoes at Chiswick.—The late Potatoes grown in the trials at Chiswick this year were examined on the 5th inst., and the cooking qualities of some of the best cropping varieties tested. Three marks of merit were recorded for the following varieties:—Major T. Neve, large white round, clean, heavy crop, and tubers of good quality. Success (Alpen), large, oval-shaped white, very good crop and quality. Crawley Prizetaker, flattish round, great crop, uniform good sized tubers of satisfactory quality. Similar marks were recorded for Boston Q. Q. (Quantity and Quality) and Conference, thus confirming their excellence of last year, and the certificates subsequently awarded.

— FLORAL DECORATIONS FOR ROYALTY IN SOUTH LONDON.—
The Prince of Wales and the Duke and Duchess of York paid a visit to
Camberwell in order to open the new South London Art Gallery,
Reading Room, and Lecture Hall on Monday last, and then the Prince
proceeded to open the Central Library and Public Garden, which are

situated a short distance away in the Peckham Road. The floral decorations on these occasions were done by Messrs. E. D. Shuttleworth and Co., Albert Nurseries, Peckham Rye, S.E.

— A SUBTROPICAL BOTANICAL laboratory has been established at Eustis, Florida, under the direction of Prof. Swingle. According to "Nature," the diseases of fruits belonging to the "Aurantiaceæ" are a special subject of investigation.

—— STRAY TOMATOES.—In reference to this subject (page 312) I always find many plants come up about midsummer on the plot of land in my garden that was cropped with Tomatoes the previous year; I have never moved them into a suitable position and given them proper attention. Would a strain selected in this manner be likely to prove more hardy?—Y.

— SIREX GIGAS (page 288).—This insect is far from rare, but is often confounded with the hornet. I have from time to time had several specimens in my possession. It has no sting, hence in this regard it is wholly harmless. It is or used to be classed as a Tenthredo, and belongs to the tribe of the saw-fly, so greatly abhorred by farmers and gardeners. It has merely an ovipositor and accessories. It is these which are mistaken for the sting.—J. E. ROGWARD.

— Gardening Appointments.—Mr. Charles Puddiphatt, for six years second in the gardens with Mr. G. Garner, late of Amberwood, Christchurch, has been appointed head gardener to Sir Anthony Cope, Bramshill House, Winchfield, Hants. Mr. J. Bennett, late gardener to the Hon. C. H. Wynn, Rûg, Corwen, N. Wales, has been appointed by Mr. Wynn to the position of steward and bailiff on the same estate. It is pleasing to note this recognition of merit, and Mr. Bennett may well be trusted to give a good account of his stewardship in his new position. We presume that Mr. Bennett will now terminate his exhibiting career. It is, however, very fitting that he should finish by securing the chief fruit prize at Shrewsbury, which he did two years in succession. Mr. W. Coleman, for many years the skilful head gardener at Eastnor Castle, Ledbury, is now appointed estate agent, and is succeeded as gardener by Mr. Frank Harris.

THE USE OF ALLOTMENTS.—In Lincolnshire, where there is an enormous number of allotments under cultivation, the reports from the different villages show that in spite of the hot season the occupiers have had a very successful harvest. In numerous instances the men have secured two quarters from a rood of Barley, and as much as 2 tons of tubers have been raised from a rood of Potatoes. The latter, especially, have paid remarkably well, and some labourers have made as much as £5 of their surplus produce after providing for their domestic requirements. The demand for additional allotments and small holdings still continues.

THE WAKEFIELD PAXTON SOCIETY.—At a recent meeting of this Society, Mr. Campbell, gardener to Mrs. Micklethwaite of Painthorpe, read an essay on "The Apple." For flavour, the essayist considered the English Apple was second to none, and if cultivated with care it would hold its own against the American and Australian Apples that were being so largely imported. During an interesting discussion Mr. Hudson strongly recommended Potts' Seedling to amateurs, as better even than Lord Suffield, being firmer, good bearing, and keeping longer. Mr. Skinner, Silcoates Nursery, offered some valuable remarks on Apple culture, and in reply to questions said that if he were planting an orchard for posterity he would use the Crab stock, but if for quick and heavy bearing for a few years the Paradise stock was preferable. He also commended judicious branch and root pruning, and condemned ringing as unnecessary.

— Gardening versus Farming.—A daily contemporary remarks:
—"What the shrewder sort of country people are doing in face of the agricultural depression is very well shown by the tabulated census returns. The farm servants, it appears, have decreased to the extent of about 10 per cent., but counterbalancing that there is a very large increase of gardeners, seedsmen, and nurserymen. In other words, the rural population, for good or ill, are acting on the belief that it does not pay to be connected with farming while there is still a living to be made in gardening and the various industries dependent on it. Never in history was gardening more popular than it is just now. Some take it up for profit, but many more for pleasure or convenience. It has become the countryman's source of livelihood and the citizen's recreation. The poor man has found out how advantageous it is to cultivate vegetables for the table, and the rich middle classes have tasted the delight of growing flowers."

- —— PROPOSED PARK FOR MANCHESTER.—It is reported that the Manchester Corporation are negotiating with the owners with the view to purchasing 134 acres of the Booth Hall Estate, including the picturesque Boggart Hall Clough, for the purposes of a cemetery and an open space.
- DR. O. LOEW, OF MUNICH, well known for his investigations of the nature of protoplasm in connection with Dr. T. Bokorny, has, we understand, been appointed Professor of Agricultural Chemistry in the University of Tokio, Japan; and Dr. D. Brandis, Professor of Forestry in the University of Bonn.
- ECKLINVILLE APPLE.—I agree with Mr. Molyneux (page 317) as to the tenderness of this Apple when ripe, but would point out the fact that it is of a sufficient size and good appearance in a green state to "market" early in the season, when it would not bruise more than other Apples.—Y.
- EARTHING UP WINTER GREENS.—Mr. G. Garner, Cadland Park, Southampton, writes—"A few weeks since I advised in this Journal those who were troubled (as we were at that time) with clubbing in winter Broccoli to thoroughly tread the ground around each plant and then draw some soil up to the stems. At the present time the advantage of doing this is plainly to be seen here in the mass of small white roots which have emanated from the stems and taken full possession of the soil."
- RIPE RASPBERRIES IN OCTOBER.—The same correspondent observes: "On October 4th I gathered a small dish of ripe Raspberries in these gardens. It is not a very uncommon occurrence I know to be able to gather the above fruit so late as this month, but the Raspberries referred to grew upon summer fruiting sorts, and were of excellent flavour."
- POTATO EXPERIMENTS IN AMERICA.—We learn from the "Garden and Forest" that some Potato experiments have been conducted at the Michigan Agricultural College for two or three years past, with a view to show the results of growing Potatoes under a mulch as compared with the ordinary method of cultivation. In a dry season it was considered that mulching may be profitable. The Potatoes grown under the mulch were of excellent quality and almost entirely free from scab. The unmulched Potatoes were badly affected with scab, and although the yield was heavier, the quality was inferior.
- DISTRIBUTION OF PLANTS. In addition to the previous announcement regarding this subject (vide Journal of Horticulture, September 28th, page 289), it is stated that the Commissioners of Her Majesty's Works and Public Buildings intend to distribute this autumn among the working classes and the poor inhabitants of London the surplus bedding-out plants in Hyde and the Regent's Park and in the Pleasure Gardens, Hampton Court. If the clergy, school committees, and others interested will make application to the Superintendent of the Park nearest to their respective parishes, or to the Superintendent of Hampton Court Gardens, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution. Any costs of carriage must be borne by the recipients.
- TEA CULTIVATION IN CEYLON.—An Indian paper observes "We have more than once lately pressed upon the attention of our planting readers that their lands cannot go on producing Tea crops from year to year from the same soil without eventual exhaustion sooner or later of some one or more of those ingredients which are essential to the quality of the Tea that the land produced when it was first cultivated It may be, and we believe it is true, that there are comparatively few Tea estates where the restorative process has become imperative; but what we contend for is timely help to those which have not yet begun perceptibly to suffer for the want of it. Tea is a much more critical product for the cultivator than Coffee ever was. Though the bush is hardy in growth, and in some senses easy to grow, the leaf when grown cannot in the course of Nature remain permanent in quality while the soil that produces it is being drawn upon year by year for the same essential ingredients. One by one, as each in turn becomes scarcer, the leaf will feel more and more the deficiency. Tea planting in Ceylon is as yet a young enterprisc. Estates that were old before they were planted with Tea, become more quickly exhausted than younger oncs; but as yet they do not form a large proportion of the whole, and they would benefit by an early application of restorative ingredients and conditions such as are not of merely stimulating nature."

- THE BRUSSELS BOTANIC GARDEN.—It would appear that the King of the Belgians takes an interest in horticulture, for on Saturday, September 23rd, His Majesty paid a visit to the Botanic Garden. M. Louis Lubbers, the Director, conducted the royal visitor through the various departments of the garden, and into the principal houses.
- THE NATURAL HISTORY SOCIETY OF DANZIG has offered a prize of 1000 marks for the best essay on the best means of producing and spreading fungus epidemics for the destruction of insects injurious to the forests in Western Prussia. The essays, says "Nature," must be written in German or French, and are to be sent in before the end of the year 1898.
- —— GREEK AND PERSIAN FLORA.—Some interesting reports of the botanical excursion of Dr. E. von Halácsy in the Pindus range in Greece, and of that of Dr. J. Bornmüller in Persia, were recently given in a foreign contemporary. Dr. Bornmüller describes the flora of the neighbourhood of Bushire in March as being especially rich and beautiful.
- —— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR SEPTEMBER.—Mean temperature of month, 55·3°. Maximum on the 4th, 75·5°; minimum on the 12th, 30 2°. Maximum in the sun on the 3rd, 128·5°; minimum on the grass on the 12th, 22·1°. Mean temperature of air at 9 A.M., 57·1°; mean temperature of soil 1 foot deep, 56·7°. Nights below 32°, in shade one; on grass ten. Total duration of sunshine in month, 134 hours, or 36 per cent. of possible duration. We had one sunless day. Total rainfall, 0·85 inch. Rain fell on twelve days. Approximate averages for September: Mean temperature, 55·5°; sunshine, 110 hours; rainfall, 2·26 inches. Another fine and dry month of average temperature. The rainfall is less than in any previous September, except 1884.—J. MALLENDER.
- —— THE WEATHER LAST MONTH.—September was chiefly bright and dry until the 22nd, but more changeable and showery afterwards. We had nineteen bright days, three of which were clear. Wind was in a westerly direction nineteen days. The total rainfall was 1.20 inch, which fell on thirteen days, the greatest daily fall being 0.40 inch on the 8th; the total is 1.81 inch below the average for the month. Temperature was higher than usual. We had not enough frost to injure the Dahlias and other tender plants, which is quite unusual for this locality. Highest shade temperature was 79° on 6th, lowest 34° on 12th; lowest on grass 29° on 24th. Mean daily maximum, 66.23°; mean daily minimum, 45.93°. Mean temperature of the month, 54.26°. Barometer, highest, 30.34 inches at 9 A.M. on 12th; lowest, 29.28 inches at noon on 30th. The garden spring ran 11 gallons per minute on 30th.—W. H. Divers, Ketton Hall Gardens, Stamford.
- JAFFA ORANGES. The British Consul at Jerusalem has recently sent to the Foreign Office a translation of a report by an engineer of the Turkish Government on a scheme for irrigating the plains and Orange gardens of Jaffa, in which, incidentally, some interesting information is given in regard to the famous Jaffa Oranges. The town, it is said, owes its importance to its climate, which is extremely favourable for Orange growing. In consequence the port is surrounded on the land side by Orange groves, covering an area of about 1780 acres. Jaffa Oranges, on account of their excellent flavour, have of late years acquired a world-wide reputation, and while some eighteen years ago they were known only at Beyrout, Alexandria, and Constantinople, enormous consignments are now exported to Europe, America, and even to India, and the cultivation has consequently increased to a very considerable extent. A special feature of Jaffa Oranges is that they will keep from thirty to forty days, and, if properly packed, for two or even three months. New Orange groves are continually being laid out, and the total number is now about 400, against 200 fifteen years ago. The exports for the last few years have averaged 36,000 boxes per annum, and owing chiefly to this trade Jaffa ranks next to Beyrout in importance among Syrian coast towns. Orange growing in Syria is conducted exclusively by natives. Each Orange garden contains about 2000 square feet of planted area, equal to about 1300 trees to 2½ acres. The trees begin to bear the fourth year after planting, but it is estimated that it takes seven and sometimes eight years before an Orange orchard yields a remunerative crop. During all this time, and even afterwards, the orchards have to be watered continually, and this irrigation is the most difficult and laborious part of the work, inasmuch as the water has to be drawn by means of primitive water-wheels from wells dug in the gardens 90 feet and even 100 feet deep.

- THE WEATHER IN WEST YORKSHIRE.—The weather in the Bingley district still continues of an open character, no frost having been experienced of any consequence. Borders and beds are still gay with Dahlias, Sunflowers, Chrysanthemums, and other flowering plants.—T. H. B.
- HAMPTON COURT GARDENS.—About 4 acres of private gardens at Hampton Court Palace, which have hitherto been maintained out of the privy purse, but to which the public have for many years had free access, are about to be transferred to the management of the Board of Works, and the expense borne by the Parliamentary vote.
- The members of this Society will open their winter season by giving a concert in aid of their library and the Gardeners' Royal Benevolent Institution. The Chairman of the evening will be Holbrook Gaskell, Esq., J.P. The Committee have also arranged an excellent series of papers for the winter meetings.—R. P. R.
- The Potato Problem (pp. 266-288).—The solution of this is that owing to the weather the crop of late Potatoes is growing again generally and well, as I experience to my cost, some becoming flabby, others watery at the end and uneatable. In many instances people took up their early Potatoes safely, and at once replanted, the result being now a good crop of sound young Potatoes. On one occasion when the tubers began growing again I let them remain till late in the season, using for the table the young ones which came, and bestowing the others in the piggery.—J. E. Rogward.
- SOPHORA JAPONICA.—As an ornamental tree this Sophora, says an American contemporary, is hardly appreciated. It is very hardy, of good habit, free from the attacks of insects and fungal diseases, and the leaves are of a beautiful dark glossy green. The yellowish white pea-shaped flowers are produced in great terminal clusters, and well-established trees flower freely during two or three weeks. This Sophora is certainly one of the best of the medium-sized exotic trees which we can plant. Large specimens are not common in America, although S. japonica was one of the first of the eastern Asiatic trees introduced into European gardens, where it was sent by Thunberg, who found it cultivated in Japan more than a century ago, and who mistook it for a Japanese tree.
- THE ORIGIN OF THE PEACH.—It has never been clearly ascertained what was the original parent of the Peach. It is, however, well known that the Peach, the Almond, and the Nectarine can all be developed, the one from the other; and it is, therefore, reasonable that all had the same origin. It has been supposed that the Almond was really the antecedent of the other two. Recently, however, there has been found a wild plant in the north of China, which is considered a good species, and has been named Amygdalus Davidiana, and it is believed that this is really the parent of the Peach and its allies. According to "Meehan's Monthly," all that is known of the Peach and Almond is that they were in cultivation as garden plants as far back as written history goes.
- A COCOA PALM WEEVIL.—A Jaffna correspondent writes:-"About here Cocoa Nut trees in full bearing, and generally the best bearing trees, are attacked by the red weevil. The presence of the larvæ is detected by a black spot, from which there flows a reddish liquid, sap or otherwise. It is asserted that a Cocoa Nut tree attacked by the red weevil can be saved by cutting a hole in it, extracting all the weevil grubs that can be found, and fumigating the hole with the smoke of burned Chilis to kill any grubs that may remain in the tree; but we do not think there is any experienced Cocoa Nut planter who believes in this remedy. We have tried it without success; and we have also tried injecting turpentine into the tree with a syringe, but this also did no good. Of the alleged remedy of driving nails into the tree we have not previously heard, and it would not be safe to try it without being sure of its efficacy, because if it should fail the larvæ would mature into beetles, and the beetles would in turn breed progeny to destroy more trees. We believe the best thing to be done with a tree attacked by the red weevil is to chop it in pieces, feed the fowls with all the grubs that can be found, and burn the remains of the tree so as to destroy any weevils or weevil grubs that may be concealed in the pieces. Our opinion is, that a tree attacked by the red weevil is doomed any way, and that all that can be done is to prevent more trees from being destroyed by the progeny of the weevil and weevil grubs which it contains."

- MR. GEORGE CANNON.—Mr. Cannon, who has been for a number of years manager in Messrs. C. Lee & Sons' nursery at Ealing, is about leaving their service, as he has taken to the business carried on for so many years by Mr. George Weeden, St. John's Nursery, Matlock Lane, Ealing. Educated at Osborn's Nursery, Fulham, and then four years with Messrs. R. Smith & Co. at Worcester, he twentynine years since entered the service of Messrs. C. Lee & Son, taking charge of the Ealing nursery, the business of which he developed to a considerable extent, and made a reputation as a successful cultivator of fruit trees, shrubs and trees of all kinds, and especially as a landscape gardener, having with marked ability laid out many gardens and pleasure grounds at Ealing and elsewhere, and planted open spaces. Mr. Cannon is so deservedly popular in the trade, and especially so at Ealing, where he is widely known, that a host of good wishes will follow him as he enters upon business on his own account.
- THE KINGSTON AND SURBITON GARDENERS' ASSOCIATION.-The new quarters of this Society, the hall adjoining the Y.M.C.A., Eden Street, was occupied for the first time by the gardeners on Tuesday evening, October 3rd, when, as previously announced, Mr. James Martin, from Messrs. Sutton & Sons, Reading, gave a most interesting address on the Begonia. There was a large attendance of members, and Mr. J. P. Trew presided. Some new members were also admitted. The lecture was illustrated by a number of plants showing diverse forms and species of the Begonia, both tuberous and fibrous rooted, also very fine double and single flowers. The President, says the "Surrey Comet," expressed the exceeding pleasure he felt in being present, honoured the gardeners for their evident desire to increase their professional knowledge, and said that life without beautiful flowers would be almost unbearable. At the close of the lecture, listened to with deep interest, a very hearty vote of thanks was proposed to Mr. Martin and to Messrs. Sutton & Sons and unanimously carried, as was also a similar compliment to Mr. J. P. Trew.
- ALLOTMENTS. -So customary is it the case now that allotments for working people are found in rural districts, that I was greatly surprised when recently in a somewhat pretentious parish in Surrey, where there is a railway station and a large population, with soil for garden purposes of the very best, to find that there were no allotments. Possibly the local authorities have not yet begun to realise that to have made no provision for allotments is becoming a matter of reprehension. Why, in myriads of thinly populated, indeed almost poor parishes, one meets with them, and it is one of the most pleasing aspects of the subject that workers manifest such desire to possess allotments, that tenants can be found in abundance provided the conditions of letting are such as can be agreed to by workers. There is a considerable number of workers of various sorts in the parish I have referred to, and it would be interesting to learn whether these have made a request for a supply. Sometimes landowners offer ground ere application is made, frequently after, and occasionally failing any supply of allotments in that way the local authorities have to intervene. That is the case here in Kingston-on-Thames, where, the land being largely in request for building, it has been found needful to invoke the aid of the Corporation, and as ground for the erection of an isolation hospital seems to be absolutely essential, the local authority have agreed to purchase 11 acres of land on the eastern side of the town, on a small portion of which to locate the hospital, and the remainder will be available for allotments. The ground is to be purchased for £140 per acre, not too high a price for the locality provided it proves suitable for the purpose. No doubt by far the best site for allotments on the north side of the town, where some 5000 of the working class reside, is the open or Lammas land on the Dysart estate, and which is at present let for six months of the year only for market garden crops. This, if it could be secured, would enable some 200 good allotment to be provided easily.—A. D.

AGAVE LEOPOLD II.

THE Agave shown in the illustration (fig. 49) is one of the best of its class in cultivation, and when exhibited by the raiser. W. B. Kellock, Esq., of Stamford Hill, at the recent Agricultural Hall Show, the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for it. As before remarked in this Journal, the plant has an interesting history. It is the result of a cross between A. Schidigera princeps and A. filifera, the latter being the pollen parent. The plant from which the seed was obtained was exhibited by Mr. Kellock about fifteen years ago at South Kensington, and was much admired by Her Majesty the Queen whilst on a visit to the gardens of the R.H.S. at that

time. The Agave depicted likewise gained the admiration of the King of the Belgians a short time ago, hence its designation, the plant having been named by permission of Leopold II. It is an effective Agave, the spines being narrow, and from 18 inches to 2 feet in length, covered with white woolly filaments.

NATURE'S HELPS TO GARDENERS.

Every one heartily in love with the world of flowers, especially when he or she takes up with one or more of them as pets to be thought over, and cared for by day and often dreamt of at night, frequently suffers from heartache. I was lately in the greenhouse of a lady who has only the last year or two acquired this love, and as I admired the glories of her Begonias, Tuberoses, Carnations, and Tomatoes, for which she took first prize at our local show, I congratulated her warmly. "Yes," said she, "but you cannot think how much time it takes, for I do it almost all

Earwigs in confinement will eat the smaller fry, but I fear that in the open they care far more for the petals of our flowers, and must be counted as decided enemies. They are very difficult to catch at their evil deeds; they prefer the dark like other evil doers, and by the light of a candle at night in the greenhouse and a pair of forceps the rascals may be caught; but it needs a sharp eye and quick and steady hand, or the enemy will soon hide himself amongst the petals and be no more seen. There are many other ways of trapping these gentry—dry Bean stalks, a bit of Apple rind in a long piece of paper folded up several times laid on the pot, or some dry moss are all useful helps. Woodlice, too, prefer darkness, and whilst in search of earwigs may often be found creeping from their haunts.

But perhaps there is no insect so troublesome to the gardener as the aphis; diminutive it may be, but its wonderful powers of reproduction make up for its lack of size. I have heard some persons declare that they only attack unbealthy plants; that is not at all my idea. Roses with splendid succulent shoots, Liliums in robust growth, Chrysan-

myself." My reply was, "Indeed I can; I see the time or its results there, and, it is a great pleasure to look at them." This she thoroughly allowed. From the greenhouse I went to the Chrysanthemums looking fairly well. She enlarged on the horrors of green fly and the other trials to which the temper of a gardener often falls a prey, and I then tried to initiate her into some of the helps that Nature, or rather the beneficent Creator, has provided as helps to us.

It seems to me that all gardeners should be taught to distinguish in the insect world their helpers from their foes. Probably the natural inclination of every gardener is to apply finger and thumb with a more or less forcible pressure to every insect that he sees travelling over his pets. It needs a closer application and a greater expenditure of time than a gardener when in full work has at his command to watch the habits of some insects, and there is little doubt that many a friend is sacrificed which would have done him service if he had left it alone. Many years ago, I recollect reading somewhere that the large yellow slug fed on smaller specimens of the slug tribe, and that therefore he might be looked upon as a friend. I believe then that slugs may feed on their fallen relatives, but only after these are dead. If this be the case cannot see that they are any helps to those who love their flowers.

themums in full vigour, and almost every plant may be rapidly covered by them and soon be made to look sickly if these pests are left to feast on it. Of course they are not lovers of the weed, but tobacco smoking is not always so harmless as it is supposed to be, and I have never known it succeed in killing aphides inside the sheath of a Lilium for instance, and whilst our Chrysanthemums are out of doors they are continually pestered by these little wretches in the heart of the shoots, where it is most difficult to dislodge them without injury to the plant.

It seems to me, then, that our aids in Nature against these little pests should be known to every gardener. There are several that for safety and certainty in executing their work are not to be equalled by any human fingers, and yet I feel that nine out of every ten gardeners would kill most of them the moment they saw them. Of these I will write later; but ere I close, having never been able to say a good word for the sparrow, let me now give him absolution thus far. I think the last two or three years I have noticed that at times he takes an aphis meal—at least, I have seen him pitch on a Rose shoot covered with green fly and appear to be enjoying a feast, and this, if it be true, is about the only honest labour for our good that I have ever seen him accomplish,—Y. B. A. Z.

A CALL AT SAWBRIDGEWORTH.

A VISIT to the famed fruit nursery of Messrs. T. Rivers & Son is at all times interesting, but at none more so than in the autumn. period the trees are laden with luscious fruit until the end of September, and once seen the sight is not readily forgotten. October finds the bulk of the crops gathered and safely housed, but the trees, although deprived of their rich appearance, are by no means devoid of interest from a planter's point of view. Now is the time when persons contemplating planter's point of view. planting should make their selections, and a visit to the nursery in question, amongst others, could be made with advantage. This is the conclusion the writer came to whilst taking a hasty run through the extensive grounds devoted to fruit growing. Although harassing in many respects, the past summer has been a grand one for fruit taken as a whole, and the trees are now in prime condition, auguring well for the For many years trees of various kinds have been raised in immense numbers at Sawbridgeworth, and it would appear that the impetus given to fruit cultivation throughout the country is being felt The demand for trees suitable for planting orchards is now enormous, but fortunately the supply has grown correspondingly. the neighbourhood referred to the soil, being a deep loam full of stamina, is peculiarly adapted for the production of good trees, and as the plantations are situated on sunny slopes the wood becomes well ripened, which, as all fruit growers know, is of the greatest importance.

APPLES AND PEARS.

All kinds of fruit trees are grown at Sawbridgeworth, upwards of 150 acres of land being devoted to this purpose. Apples and Pears, as may be expected, come in for their share of attention, these being well Of the former no less than nearly 600 varieties are grown, but Mr. T. F. Rivers is of the opinion that fifty of these would be sufficient, and in many cases the list might be further condensed. Still there are persons who will grow both Apples and Pears of a common character, and so long as a demand exists for such varieties the supply will be furnished. Notwithstanding, as before remarked, Mr. Rivers considers that too many varieties are planted, and when such is "Upright done the results are not always of a satisfactory nature. growing trees of choice reliable sorts should be planted," observed our guide, and to illustrate his remark he pointed out a plantation of Cox's Orange Pippin. The trees in this case are planted in rows 12 feet as under and 6 feet apart in the rows, but will eventually be thinned out to double that distance. All are half-standards, with well trained heads, and the ground beneath is planted with Strawberries. An orchard of this kind cannot be other than profitable, and it is worthy of imitation. The foregoing is but a case in point, for many similar instances are to be seen here. In addition to these, however, there are acres of young trees, two, three, and four years old, all now in excellent con-The Apples are represented by bushes, pyramids, dition for planting. and standards, on the Nonesuch, Paradise, and Crab stocks, and all are characterised by remarkably fine growth. The young shoots are long, and in many cases as thick as a man's finger, and, as may be expected after a prolonged period of sunshine, have ripened wonderfully well. They are, moreover, bristling with fruit buds in a manner that one does not always find. Bismarck is largely grown, and so are Bramley's Seedling, Duchess of Oldenburg, Cox's Pomona, Betty Geeson, Lane's Prince Albert, Blenheim Orange, Nancy Jackson, King of the Tomkins County, and many other choice varieties. Enormous brightly coloured samples of the above mentioned Apples were displayed in the fruit room, but Mr. Rivers is not a believer in huge Apples. Firm, well coloured, medium-sized fruits are preferred by the Sawbridgeworth principal.

What has been said in regard to Apples applies with equal force to Pears. Of these there are plenty to select from, and intending planters will find trained trees for walls and espaliers as abundant as cordons, and bushes as numerous as pyramids. These are worked on the Quince and Pear stock, and in certain cases are double grafted, which in some varieties is a great advantage. All the select kinds are grown, and the trees being dwarf and well trained are under control. They have, notwithstanding the drought, made fine growth this season, and the wood is so well covered with fruit buds that trees transplanted now would, if allowed, carry a good crop of fruit next season. Like the Apples, large Pears are not appreciated here, and although some wonderfully fine samples are grown, Mr. Rivers, for private use, pins his faith on a seedling Bergamot of his own raising. This is rather a small Pear, sweet and juicy, and of a delicious flavour. Conference is a new seedling Pear that is likely to prove a valuable market variety, the tree being most prolific. The fruit is large, flesh melting, juicy, and rich. It is doubtless a Pear of the future.

PLUMS AND CHERRIES.

Plums form a special feature, and thanks to the efforts of the Sawbridgeworth firm in raising new varieties some delicious fruits are now forthcoming. Thousands of standard, pyramid, dwarf, and trained trees are grown in a similar manner to the other fruits, and by making a choice selection it is possible to have ripe Plums from open-air trees from early in July till October. All the leading varieties are represented, but a large breadth of Rivers' Early Prolific arrests attention. This is a grand culinary variety, and one that should be found in every orchard or garden. Although but medium in size, it is one of the heaviest Plums in cultivation, and is a prodigious cropper. For making preserves this is a valuable fruit, and for that purpose it is being extensively cultivated. As an early dessert Plum The Czar is very popular, and consequently the supply is maintained according to the demand. As

is generally well known, the fruit is large, rich, and good flavoured, usually ripening the end of July. Another valuable market Plum raised at Sawbridgeworth is the Monarch, and anticipating a brilliant future for this variety Mr. Rivers has grown it extensively. Trees of various sizes, suitable for orchard and garden planting, have been produced, and those three years from the graft have this year borne heavy crops of fruit. It is a late variety, ripening in ordinary seasons at the end of September, although this year the fruit was fit to gather several weeks earlier. The fruit is very large, of excellent quality, and the tree is an abundant bearer. Grand Duke is another splendid late Plum that might be individualised out of the many grown here, this variety being sometimes in prime condition as late as October.

Regarding Cherries a few words will suffice, for the firm has long since gained a reputation for these. Visitors to the summer shows in and around the metropolis have often been charmed with the delicious looking fruits sent by Messrs. Rivers, and no doubt will be again. Trained trees on the Mahaleb are a feature here, cordons also receiving special attention. The Morello is now grafted on this stock, and has been found useful to be grown as pyramids in gardens. Apricots are likewise looking well, the trees being vigorous in growth, which has

become exceptionally well ripened.

FRUIT TREES IN POTS.

This perhaps is the most interesting phase of fruit culture, and to see it well carried out a visit to Sawbridgeworth is desirable. Here we find Apricots, Apples, Cherries, Pears, Plums, Peaches, Nectarines, Figs, Oranges and other fruit trees in pots grown very extensively. Numerous houses are devoted to their culture and apparently with great success. Last week trees of the Apple Bijou from 2 to 3 feet high and in 8 and 9-inch pots were carrying two or three dozen fruits of excellent quality. Other choice kinds are similarly cultivated, and the same may be said of Pears. The latter are very fine, and it is surprising that they are not more generally grown in pots. Trees about 4 feet in height and bearing from one to two dozen fruits of a large size are very plentiful. The following varieties are recommended by Mr. Rivers as being suitable for growing in pots.—August: Jargonelle, Beurré Giffard and Clapp's Favourite; September: Williams' Bon Chrêtien, Beurré d'Amanlis, Madame Treyve, Beurré Superfin and Souvenir du Congrès; October: Louise Bonne of Jersey, Fondante d'Automne, Beurré Hardy, Gansel's Bergamot, Marie Louise, Maréchal de Cour, Glou Morçeau and Pitmaston Duchess; November: Durondeau, Beurré Bachelier and Beurré Diel; December: Winter Nelis, Josephine de Malines and Bergamotte d'Esperen; January: Nouvelle Fulvie. After fruiting, the trees are stood outdoors in sunny positions to ripen the wood properly.

Peaches and Nectarines too are exceedingly good, and the trees are now

Peaches and Nectarines too are exceedingly good, and the trees are now being repotted. They vary in height from 3 to 12 feet, many of the latter being remarkable specimens of cultural skill. Trees of this kind in suitable size pots bear five dozen fruits of superior quality and could be induced to carry more. They are grown in a compost of loam, decayed manure and chalk, and during the season are top-dressed with a mixture of horse droppings, night soil, and kiln dust. In this the roots ramify, and by the autumn form a matted mass. Trees of a smaller size are plentiful, and these produce one to two dozen fruits. Such trees as these might advantageously be given a place in every garden where a suitable glass house exists for their reception. Plums in pots are likewise given special attention, and the same can be said of Figs and other fruits, although the majority of the trees are now maturing their wood in the

open air.

GRAPE VINES AND ORANGES.

A brief reference must be made to the pot Vines. A close inspection of these was not made, but it could be easily seen in passing that they bear the impress of good cultivation. There are hundreds of well ripened stout canes that will produce good fruit next year if properly treated. These are for the most part under glass, but where an abundance of ventilation is given. The orangery is an interesting feature here, inasmuch as about fifty varieties of Oranges, Lemons, and Citrons are grown. The trees are in pots, ready for transit, and most of them are now carrying a good crop of fruit, which is commencing to ripen. Generally home-grown Oranges as seen in private gardens are not of an excellent quality, but matters are entirely different at Saw-bridgeworth. An opportunity of tasting a fruit convinced the writer that, given a good variety and grown under proper conditions, Oranges cultivated at home are superior to the majority of those imported from The chief essentials in the successful cultivation of Oranges are obviously moderate heat and a well ventilated house, so as to maintain rather a dry atmosphere, which imparts flavour to the fruit. There are many other features at this nursery, but pressure on our space forbids further details. It may be mentioned that despite the extreme drought the young grafted trees of all kinds of fruit are looking remarkably well, the scions having taken well, this being partly the result of deep and judicious cultivation, which assisted much in reserving moisture

Although the fruit trees above referred to are so largely grown by Messrs. T. Rivers & Son, it must not be thought that they constitute the whole of the Sawbridgeworth stock. Raspberries are well represented, there being thousands of canes of such standard sorts as Hornet, Fillbasket, Baumforth Seedling, and Lord Beaconsfield, the last named a comparatively new variety of great excellence. The autumnal Raspberries are also extensively cultivated, the best of these being the October Red and October Yellow, both reliable varieties. All the most popular Strawberries are likewise grown, the young plants being strong

and vigorous. Crabs of various kinds suitable for decorative purposes receive attention, as also do Coniferæ, evergreens, and other ornamental shrubs. Nor are Roses forgotten, for in addition to the hundreds of plants growing outdoors several houses are devoted to their culture. remarkably fine vigorous young plants of Maréchal Niel are noticcable, and these would under ordinary circumstances produce an abundance of bloom next spring. The stems are thick, upwards of 12 feet in length, and well ripened.—C.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 10TH.

CONTRARY to general expectation, there was a fine display at the Drill Hall, Westminster, on this occasion, fruit being particularly good. Orchids were only moderately represented, the same applying to the other floral exhibits.

FRUIT COMMITTEE.—Present: Phillip Crowley, Esq. (in the chair); Messrs. J. Lee, H. Pearson, T. Francis Rivers, J. Cheal, T. J. Saltmarsh, P. C. M. Veitch, G. Bunyard, Alex. Dean, Harrison Weir, J. A. Laing, W. Bates, G. Mills, Chas. Ross, G. H. Sage, Jas. Hudson, Geo. Wythes, H. Balderson, F. Q. Lane, G. Norman, A. Moss, the Rev. W. Wilks, and

Dr. Hogg.

Messrs. J. Veitch & Sons, Chelsea, sent a splendid collection of Apples and Pears, comprising upwards of 200 dishes. The Apples were large and handsome, as well as being richly coloured. Lane's Prince Albert, Watson's Dumpling, Lord Derby, Mère de Ménage, Beauty of Stoke, Mrs. Barron, Sandringham, and Bismarck were among the best. The Pears were also fine for having been grown on pyramid trees, especially the new variety Beurré Tonqueray, a splendid hardy Pear, in season during October, for which a first-class certificate was A gold Knightian medal was recommended. Messrs. G. Bunyard & Co., Maidstone, also sent a large collection of Apples and Pears, about 160 dishes of fruit being staged. The Apples in this contribution were very richly coloured. Noticeable amongst others were Fearn's Pippin, Woodstock Pippin, Cellini, Wealthy, King of Tompkins County, Worcester Pearmain, Mabbott's Pearmain, Gascoyne's Scarlet Seedling, Cobham, and Pearson's Plate. The best of the Pears comprised Madia January Pippin, Consequence of Pearson's Plate. Marie Louise, Beurré Bachelier, General Todtleben, Beurré Diel, Grosse Calabasse, Pitmaston Duchess, and Beurré Bosc. A gold Knightian medal was recommended.

P. Saillard, Esq., Buchan Hill, Crawley (gardener, Mr. John Martin), sent a fine collection of Apples and Pears, and a silver Knightian medal was recommended. The best of the Apples were Warner's King, Peasgood's Nonesuch, Cox's Pomona, and Fearn's Pippin. The Pears also were exceedingly good. Messrs. J. Cheal & Sons, Crawley, sent ten varieties of Pears and a dish of the recently introduced Atalanta Apple. Among the Pears were Princess, Duchesse de Nemours, Duchesse de Mouchy, Kieffer's Seedling, Magnate, Bon Vicar, Belle William, Beurré Alexander Lucas, and Belle de Bruxelles. A dish of Crawley Prize-

taker Potato was also shown by the same firm.

Messrs. H. Lane & Son, The Nurseries, Berkhampstead, had a dish of splendid Lane's Prince Albert Apple. Major Hambling, Dunstable, sent two dishes of an Apple named Hambling's Seedling. This is a large Apple, greenish-yellow skin, and a first class certificate was awarded. Mr. Sidney Ford, Cowfold, Horsham, Sussex, sent three dishes of Marie Louise Pears, and Mr. E. Molyneux, Swanmore Park, Bishop's Waltham, had some fine Bramley's Seedling Apples, the produce of maiden trees planted in 1891. A vote of thanks was accorded for this exhibit. Messrs. Laxton Brothers, Bedford, sent a dish of Apple Mr. Hooper, a well coloured variety. C. C. Tudway, Esq., Wells, Somerset, staged twelve Doyenné du Comice Pears, the total weight being 13 lbs. A bronze Banksian medal was recommended. Lane, Palgrove, Diss, sent a seedling Apple, but no award was made. The same exhibitor had two dishes of Grosse Calabasse Pears, and a vote of thanks was accorded. A. W. Druce, Esq., Upper Gatton, Merstham (gardener, Mr. W. Mancey), sent two dishes of very large Pitmaston Duchess Pears, for which a bronze Banksian medal was recommended. It was stated that twenty-seven fruits, weighing 38 lbs. 2 ozs., were taken from one cordon tree. Mr. J. Masterson, Weeston House Gardens, Shipston-on-Stour, sent two dishes of Pears (cultural commendation). A grand Smooth Cayenne Pine, weighing 9 lbs., was exhibited by Mr. O. Thomas, Royal Gardens, Windsor. A cultural commendation A similar honour went to Mr. S. Mortimer, Swiss Nursery, Farnham, for a box of Jones' Perfection Tomatoes.

A magnificent collection of Apples and Pears was shown by Messrs. J. Laing & Son, Forest Hill, prominent amongst which were Apples King of the Pippins, Royal Russet, Cox's Orange Pippin, Beauty of Kent, Alfriston, Golden Reinette, Grenadier, Hollandbury, and Blenheim Orange, all well coloured. Noticeable amongst the Pears were Souvenir du Congrès, Beurré Clairgeau, Glou Morçeau, Duchesse d'Angoulême, and Maréchal de Cour (silver Knightian medal). Mr. W. Crump, Madresfield Court Gardens, sent an admirable collection of Pears, amongst which were some grand examples, notably Pitmaston Duchess, Beurré Diel, Marie Louise, Doyenné du Comice, Beurré Bosc, Van Mons Leon Leclerc, and Beurré Capiaumont (silver Knightian medal). Mr. Owen Thomas, Royal Gardens, Windsor, arranged a creditable collection of Pears, which was comprised of sixty dishes of the leading varieties (silver Banksian medal). Mr. John Watkins, Withington, Hereford, staged a collection of Apples and Pears, cider varieties being very prominent amongst the Apples. A silver Knightian medal was recommended. Mr. Jas. Day, Galloway House, Wigtonshire, was recommended a bronze Banksian medal for a collection of Pears, which consisted of some excellent fruits. Mr. J. Miller, gardener to Lord Foley, Esher, staged a Gourd weighing 154 lbs., for which he was awarded a cultural commendation.

In addition to the Potatoes mentioned on page 332, first-class certificates were awarded for the following varieties: - Jeanie Deans, shown by Messrs. Carter & Co., High Holborn; Conference, Mr. Dean, Ealing; Early Regent, Messrs. J. Veitch & Sons, Chelsea; Nelly Langley, Mr. H. Fletcher, Annerley; Radcliffc Kidney, Mr. Jelley. Awards of merit went to Onions—Southport Yellow Globe, Southport

Red Globe, and Deverill's Cocoanut, Mr. H. Deverill, Banbury; Globe Madeira, Italian Tripoli, and Prizetaker, Messrs. Vilmorin, Andrieux

and Co., Paris.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); Messrs. Owen Thomas, Robert Owen, H. Herbst, R. Dean, G. Stevens, H. B. May, C. J. Salter, J. Jennings, R. B. Lowe, Chas. E. Pearson, J. D. Pawle, W. Watson, Henry Cannell, Chas. E. Shea, T. Baines, Chas. Jeffries, J. T. Bennett-Poë, Geo. Gordon, Edward Mawley, and the Rev. H. H. D'Ombrain.

Mr. S. Mortimer, nurseryman, Rowledge, Farnham, arranged a group of Show and Fancy Dahlias, amongst which were some excellent blooms (bronze Banksian medal), and also three boxes of Stephanotis floribunda, the flowers being of much merit. Mr. A. H. Rickwood. gardener to Dowager Lady Freake, Fulwell Park, Twickenham, staged a fine group of seedling Begonias. The blooms being arranged with Fern and Asparagus fronds produced a fine effect. A highly creditable collection of Chrysanthemums, prominent amongst which were La Cherine, Coronet, Duchess of York, Cesare Costa, and Comte de Germiny were exhibited by Mr. Wells, Earlswood. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, staged a basket of Aster grandiflora, the plants in which were profusely flowered. The same exhibitor also had a small collection of Dahlias and Nerines. Mr. Ware received a first class certificate for Nerine elegans alba, and an award of merit for Pompon Dahlia Emily Hopper, and single Dahlia Ettie Swan, for descriptions of which see below. Messrs. Pitcher & Manda, United States Nurseries, Hextable, put up some magnificent Chrysanthemums. Noticeable in this exhibit were Mrs. F. L. Ames, Bouquet des Dames, Vm. Seward, Golden Wreath, and many promising seedlings. A group of Adiantums was staged by Mr. H. B. May, Dysons Lane Nurseries, Upper Edmonton. The plants were clean and well grown, and A. farleyense, A. formosum, A. tetraphyllum acuminatum, A. Lathomi, and A. peruvianum were amongst the best (silver gilt Flora medal).

Mr. Robert Owen, Maidenhead, showed some very fine Chrysanthemum blooms. Rose Wynnc, Mrs. P. Blair, and Edith Owen were very prominent. A box of seedling Begonias was staged by G. A. Farini, Esq., Dartmouth Lodge, Forest Hill, S.E. From the Royal Gardens, Kew, came some fine seedling Streptocarpus, and also Tecoma Smithi, Kniphofia modesta, Ptychoraphis angusta (first-class certificate), Solanum Wendlandi (first-class certificate), Disa Premier (first-class certificate), Bomarea patacænsis (first-class certificate). Messrs. Jas. Veitch & Sons staged beautiful hybrid Rhododendrons of the Javanicojasminoides section, amongst the best of which were luceo-roseum, Maiden's Blush, amabile, and Lord Wolseley. A box of hybrid Strepto-carpus were also staged, and also a basket of Caryopteris mastacanthus. The same firm also showed plants of Carnation Mdlle. There'se Franco, for which they were accorded an award of merit (see below), and also a basket of Amasonia punicea, which, arranged with Pteris Victoriæ, produced a very striking effect. Messrs. Perkins & Sons, Coventry, received an award of merit (see below) for Cactus Dahlia Purple Prince. Mr. H. J. Jones, Ryecroft Nurseries, Lewisham, showed a basket of Pompon Dahlia Ryecroft Gem. Mr. R. Sanders, gardener to Alfred de Rothschild, Esq., Halton, Tring, exhibited nine baskets of fibrous-rooted Begonias, amongst which B. semperflorens atropurpurea, B. s. La France, B. Afterglow, and B. floribunda rosea were particularly noticeable (silver Flora medal). Messrs. Henry Cannell & Sons, Swanley, showed Chrysanthemums in excellent condition, also some Dahlias, amongst which were Old Gold, to which an award of merit was accorded (see Messrs. Cannell also arranged a box of their celebrated Zonal Pelargoniums, amongst which were Madame de Bondeville, Etoile de Lyon, Souvenir de Mirande, Jacques Callot, M. Duterail, and a charming

seedling (bronze medal).

Messrs. R. Veitch & Son, Exeter, showed Plumbago Larpentæ, Zauschneria californica, Pink Ernest Ladhams, and Colutea arborescens purpurea. Cactus Dahlia George Phippen was shown by Mr. J. Phippen, Reading; and Dahlia Miss Arnold by Mr. J. Arnold, Stoke, Devonport. Mr. A. Waterer, Woking, sent foliage of Quercus americana splendens (first-class certificate, see below). Messrs. G. Bunyard & Co. had a collection of ornamental foliage (bronze medal).

collection of ornamental foliage (bronze medal).

In the class for twelve bunches of hardy herbaceous flowers, Mr. G. H. Sage, The Gardens, Ham House, Richmond, was deservedly awarded the first prize. The exhibit was composed of Aster multiflorus, A. sibericus, Anemone japonica alba, Erigeron speciosum, and Solidago rigidus amongst others. Miss Debenham, St. Peters, St. Albans, was placed second with a fair collection.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); Messrs. O'Brien, De B. Crawshay, H. M. Pollett, Thomas Statter, H. Ballantine, E. Hill, H. Williams, W. H. White, T. B. Haywood, and S. Courtauld.

Messrs. Hugh Low & Co., Clapton, sent a small group of Orchids comprising some choice species and varieties. Amongst others Vanda Kimballiana delicata, Cattleya maxima, Cypripedium radiosum superbum. Some plants of Lilium nepalense made a good background (silver Banksian medal). A J. Hollington, Esq., Forty Hill, Enfield, sent a plant each of Cattleya Davisi, Cypripedium Smithi, and C. Richardsoni. A very fine form of Odontoglossum grande was shown by J. Foster Alcock, Esq., Northchurch, Berkhamstead, Herts, who also had a good form of Cattleya labiata. Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, showed Cattleya × Chloris (first-class certificate); Cypripedium × Arthurianum pulchellum and Cattleya × Pherdona (award of merit). A hybrid between C. maxima and C. intermedia. Messrs. F. Sander & Co., St. Albans, contribute! a small intermedia. Messrs. F. Sander & Co., St. Albans, contribute! a small group of Cattleyas and Cypripediums, also plants of Pescatorea Klabrochorum and Phalænopsis Lowi (silver Banksian medal). Sir Trevor Lawrence, Bart., Burford, Dorking, sent a plant of Cypripedium conco-Lawre having a neatly formed flower with two lips, also Dendrobinum Mirpellianum. A basket of the bright flowered Habenaria militaris came from the same source (silver Flora medal). Messrs. B. S. Williams & Son, Upper Holloway, had a small group tastefully arranged with Ferns (silver Banksian medal).

The L'Horticulture Internationale, Brussels, sent some choice species. Amongst these were Cartleya Warsqueana fascinator (award of merit) Cypripedium Spicerio Lowianum (award of merit), Cattleya Eldorado Oweni, Lælia elegans Lucani (award of merit). and a grand form of Cypripedium Rothschildianum. A first-class certificate was also awarded for Cattleya Eldorado Lindeni. The same firm also staged a fine plant of Hæmanthus Lindeni (first-class certificate), and Anthurium Wambeckianum, a white form (silver Flora medal). S. G. Lutwyche, Esq., Eden Park, Beckenham, staged a collection of Cypripediums, Odontoglossums, and a fine plant of Zvgopetalum Mackayi amongst other Orchids (bronze medal). Messrs. W. L. Lewis & Co., Southgate, sent a plant of Habenaria cinnabarina, for which a botanical certificate was awarded. Major-General Berkeley, Bitterne, secured an award of merit for a plant of Odontoglossum Uro-Skinneri album.

CERTIFICATES AND AWARDS OF MERIT.

Anthurium Wambeckianum (L'Horticulture Internationale). — A strong growing form, with a pure white spathe (first-class certificate).

Bomarea patacoensis (Kew Gardens).—A beautiful species, with orange red flowers (first-class certificate).

Cattleya Chloris (J. Veitch & Sons).—This is a splendid hybrid, being the result of a cross between C. maxima and C. Bowringiana. The sepals and petals are dark mauve, and very distinct. The lip is large, heavily suffused with rich purplish crimson (first-class certificate).

Cattleya Eldorado Lindeni (L'Horticulture Internationale, Brussels). —This is a good form with medium sized flowers. Sepals and petals roay mauve, lip fringed deep purplish crimson, throat orange yellow

(first-class certificate).

Cattleya Pheidinæ (J. Veitch & Sons).—This is a hybrid, being the result of a cross between C. maxima and C. intermedia. The sepals and petals are white faintly tinged with pink. The lip is exceedingly pretty, being white, veined crimson and rich yellow in the throat (award of merit).

Cattleya Warsequana fascinator (L'Horticulture Internationale).—A magnificent form that attracted much attention. The sepals and petals are large, and of a rosy mauve shade, the lip being richly coloured with

a white margin (award of merit).

Carnation Mary Godfrey (W. J. Godfrey).—A pure white flower with fringed petals, Clove-scented (award of merit).

Carnation Reginald Godfrey (W. J. Godfrey).—A delicate pink Clove-scented variety, good form, fringed petals (award of merit).

Carnation Malle. Thérèse Franco (J. Veitch & Sons).—A fine

variety, with large salmon-pink blooms, faintly Clove-scented (award of merit).

Chrysanthemum Mrs. P. Blair (R. Owen).—An incurved Japanese,

silvery pink, suffused carmine (award of merit).

Cypripedium Spicerio Lowianum (L'Horticulture Internationale).-A beautiful Cypripedium. The petals are narrow and twisted, green heavily spotted with chocolate, bronzy tips. The dorsal sepal is white, with a green base, tinged crimson, the lips being a dull green (award of merit)

Dahlia Emily Hopper (T. S. Ware).—A Pompon yellow variety of

good form (award of merit).

Dahlia Ettie Swan (T. S. Ware).—A single variety, with terra cotta coloured flowers, the lower part of the petals being red (award of merit). Dahlia Purple Prince (Perkins & Sons).—A rich purplish magenta Cactus variety (award of merit).

Dahlia Miss Arnold (J. Arnold).—A decorative variety, rosy pink flaked with purple in the centre (award of merit).

Dahlia Old Gold (H. Cannell & Sons).—A beautiful Cactus variety of a shade that is indicated by the name (award of merit).

Disa Premier (Kew Gardens).—This is a hybrid, the result of a cross between D. Veitchi and D. tripetaloides. The plant shown had one spike which bore six flowers. The latter are very attractive, being deep rose pink (first-class certificate).

Hæmanthus Lindeni (L'Horticulture Internationale).—The plant exhibited bore three large spikes of flowers of a salmon pink colour

(first-class certificate).

Lælia elegans Luciana (L'Horticulture Internationale).—The plant of this that was exhibited had one spike which bore six flowers. sepals and petals are greenish white, tinged with rose. The lip is dull white, margined rich purple crimson (award of merit).

Nerine elegans alba (T. S. Ware).—This is a pure white variety. The plant shown was about 9 inches high, and bore one spike of flowers (first-class certificate).

Odonto, lossum Uro-Skinneri alba (Major-General Berkeley).—A pretty variety, with greenish yellow sepals and petals, and a pure white

lip (award of merit).

Ptychoraphis angusta (Kew Gardens).—A graceful Palm with finely

cut foliage (first-class certificate).

Solanum Wendlandi (Kew Gardens).—A handsome plant, with large

pale blue flowers (first-class certificate).

Tecoma Smithi (Kew Gardens)—This is a hybrid from T. capensis and T. velutina. Three plants were shown, and they bore rich yellow flowers singed with brownish red (first-class certificate).

Quercus americana splendens (A. Waterer).—A variety with large richly coloured foliage (first-class certificate).

At the afternoon meeting Mr. W. Crump, Madresfield Court Gardens, Malvern, read an essay on "Pears." Being an experienced grower Mr. Crump dealt with his subject in a practical and interesting manner, and was attentively listened to by an appreciative audience.

CHRYSANTHEMUMS AT BATTERSEA PARK.

THE Exhibition of Chrysanthemums by the London County Council will be open to the public in the Frame Ground of this park on Saturday, 14th October.

A CHRYSANTHEMUM BOOK.

WE understand that Mr. John Newton of Temple Gardens intends to bring out the nineteenth edition of his work on the Chrysanthemum, the first edition of which appeared in 1871.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

WE have received the annual report of this Society, whose Exhibition this year will be held at the Northfield Hall, Highgate, on November 2nd and 3rd. The report states that the £10 challenge cup last November was won by Mr. Rowbottom, gardener to H. R. Williams, Esq.; he having won it twice in succession, it now becomes his own property. Some moderate prizes are offered, and there should be a good display at the Exhibition. Mr. E. Vince, Highgate Cemetery, is the Secretary.

AN EAST END CHRYSANTHEMUM SHOW.

THE East London Amateur Chrysanthemum and Floricultural Society will, we are informed, hold their third annual Exhibition on November 6th, 7th, and 8th in the Queen's Hall and Winter Garden of the People's Palace, Mile End Road, E. The rates of admission to the Show will be fixed at such a price as to allow the poorest inhabitants of that thickly populated locality to enjoy the benefits of a bright display of flowers. The Secretary is Mr. W. F. Clarke, 23, Parmiter display of flowers. The Secre Street, Cambridge Heath, N.E.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual Show of the above Society will be held in the Corn Exchange, Sheffield, on November 17th and 18th. A comprehensive schedule has been prepared, and liberal prizes are offered, the leading classes in the cut flower section being for twenty-four incurved blooms, and a similar number of Japanese, in not less than eighteen varieties in each case. The prizes in both classes are £8, £5, £3, and £2, which should bring a good competition. According to the annual report, the Society, financially, is in a strong position. Mr. W. Houseley, 177, Cemetery Road, is the Secretary.

CHRYSANTHEMUMS IN IRELAND.

As show days loom in the near distance with all their attendant hopes and fears, it is somewhat disappointing to find so few recording their experience of an exceptional season in this department. I would venture to supplement the short notes previously sent of prospects of Chrysanthemums this side of the Channel, with one brief note of thanksgiving that "All are safely gathered in ere the winter storms begin." There is another side of the question on which I could wish an abler pen than mine to touch, viz., the valuable recent article on the bud mite (page 291). It is a matter of vital importance to know our enemies and how to fight them, and I take on myself to return thanks of growers generally, and particularly from—E. K., Dublin.

HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY.

MR. EDW. HARLAND, one of the Honorary Secretaries of this important provincial Society, favours us with the illustration (fig. 50) of the "Hull cups," of which it will be admitted there is an imposing display.

The challenge vasc (central figure on pedestal), value 20 guineas, is presented by James Reckitt, Esq., in the 100 square feet group class. The upright silver cups on each side of the central vase, value £5 5s

each, are offered for twenty-four incurved blooms, and twenty-four Japanese, in separate classes, a money prize of £10 going to the winner in each case. Are not these the best prizes of the year for twenty-four blooms?

The two end silver cups on pedestals, value £2, are given by Messrs. E. P. Dixon & Son for twelve blooms incurved, and twelve blooms Japanese, respectively, in addition to the money prize. The class is confined to growers twenty miles round Hull. The two silver cups on the table, value £2 each, are given by the Society for twelve incurved blooms, and twelve Japanese blooms in the amateurs' class.

The challenge plate, in a case, value £5 5s., is for the dessert table decorations, ladies' class.

I) The encouragement thus afforded by the Hull Society and its generous friend ought to insure a high class and spirited competition. The illustration is reproduced from a photograph by Messrs. Kirk & Co., Limited, Hull, Leeds, and Liverpool. The exhibition will be held on November 15th and 16th.

NATIONAL CHRYSANTHEMUM SOCIETY.

On Monday evening last, the 9th inst., a meeting of the General Committee of this Society was held at Anderton's Hotel, when Mr. R.

ultimately be placed before the schedule sub-committee. The principal speakers were Mr. Beavan, Mr. Rowbottom, Mr. Gibson, Mr. Geo. Stevens, Mr. G. Gordon, Mr. Crane, Mr. Harman Payne, Mr. Witty, Mr. Wynne, and one or two representatives of affiliated Societies. Mr. Pearson replied and received a vote of thanks for his paper, which it is intended shall be ultimately printed in the schedule for the coming year, together with the remarks of those who took part in the discussion.

SOFT VERSUS HARD COLD WATER FOR PLANTS.

I HAVE been deeply interested in the correspondence which has been carried on for several weeks in the Journal under the above title. But what is meant by the words, "hard water?" I have read every word which has appeared in the Journal, but fail to find a definition of the word "hard." If I may be allowed to give my opinion on what I take If I may be allowed to give my opinion on what I take to be the meaning generally understood by gardeners of "hard water," I should say it is nothing more or less than water which contains a large per-centage of lime.

Your correspondent "J. B. R." (pages 239 and 286) has made mention, to serve as illustrations, of the market growers, but I cannot

FIG. 50.—HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY'S CUPS.

Ballantine took the chair. The minutes of the previous meeting having been confirmed, and various letters read resulting from new nominations and elections, the Secretary reported that prize money to the amount of £17 17s. 6d. was awarded at the recent September Show, of which £3 was contributed by Messrs. Sutton as special prizes for vegetables. There were also three medals awarded to exhibitors on that occasion. A rough financial statement was submitted, showing the receipt of £201 4s. 10d., a much larger sum than was received jast year up to the same date. The Secretary also announced that since the up to the same date. month of February last ninety new members had been elected and eight societies affiliated. A further addition was then made to the list by the nomination and election of eighteen new members and Fellows. reserve fund now amounts to nearly £40 and it was hoped the fund would be largely increased by the close of the year.

The chief interest of the meeting was the reading by Mr. C. E. Pearson of Chilwell of a paper entitled "How to Improve our Chrysanthemum Shows," which was listened to with very great interest and attention. Mr. Pearson dealt with the whole subject, from the staging of the cut blooms in long monotonous lines upon the show board, and instanced the improved American method of setting up the blooms in vases with long stems, to the formal method of arranging the groups, and the questionable utility of the rigidly trained specimens.

An interesting discussion thereupon ensued, in which a large number of members took part. Many of the remarks were favoura le to Mr. Pearson's suggestions, and the subjects upon which he touched will

see how this has strengthened his argument, unless he can also prove that the water these growers use contains a large per-centage of lime; because, in my opinion, it is the lime that does the mischief, or at least the greater part of it, and not the low temperature. "J. B. R." must bear in mind that the lime, where it is contained in water to the extent of 4 or 5 per cent., as is the case in the neighbourhood from where I write, has a very injurious effect on plants when used in a cold raw state. Why? Because it, so to speak, burns the small hair-like roots or spongioles, hence the action of chill on them. Your correspondent has asked why it is that the market growers who have to depend on water drawn directly from the companies' mains succeed in growing such fine plants if cold hard water is "slow poison." I think that most of the water which is used in London and neighbourhood is drawn from the Thames and New River. This being so, if "J. B. R." will analyse it, he will probably find that it contains very little lime indeed; moreover, it cannot be said that it is cold to the extent of chilling the roots of plants after being exposed to the sun and air so long, even if it is confined, and undergoes the various processes to which it is subjected. At any rate, 1 venture to say that the difference in temperature between the London water, which has to be pumped up from a depth of over 200 feet, and that of the town from whence I write, is very considerable. Herein, then, I think, lies the whole question at issue between your several correspondents.

Would it not be useful as well as interesting if each of those gentlemen who have taken part in this question of hard and soft water would send to the Journal office a statement as to the depth from which the

water they have to use is drawn, its temperature, and the amount of lime it contains? I shall be pleased to do so, and I cannot but think that this would help to convince the readers of this paper that it is not the low temperature merely, but the combination of that and lime. I am led to this conclusion from the fact that the water I have for using in the kitchen garden is drawn from a lake fully exposed to the air and sun, but which contains very little lime. Rhododendrons, Azaleas, Heaths, Kalmias, and similar plants flourish when watered with it and no other water while in the garden; but immediately they are removed to the conservatory, where the water is drawn from the companies' mains, these plants very quickly turn a yellow sickly colour. Frequently they have to be shaken out of the old soil and repotted before they can be restored to their former health.

The water from the pond is surface water, as there are no natural springs to feed it, and in the winter, while many hundreds of people are skating on it (for it is some 9 acres in extent), it is used in its cold state; yet the plants flourish. Does not this point to the absence of lime, and substantiate what I have suggested above? I am speaking of stove and greenhouse plants, but the same applies to Chrysanthemums and other plants outside. My neighbours have been complaining this summer about the pale yellow colour of their Chrysanthemums; all of them attribute it to being compelled to use the water from the mains

after exhausting their store of soft rain water.—T. A.

YOUR correspondent Mr. Dunn (page 317) is certainly to be congratulated on the ingenious manner in which he conducts his case in this discussion, but I fear his ingenuity will avail him very little. his first communication he modestly sweeps the entire field of practical horticulturists out of existence by declaring in bold tones—any person who watered his plants with water from the tap or pump were verily killing them; again, that it was quite impossible to keep plants clear of insect pests by the use of the "obnoxious drug;" finally winding up his remarks by challenging anybody to prove by practical demonstration that his ideas were other than correct.

Judging from his last communication he has obviously been reduced to his last shot, and that a harmless one. Mr. Dunn has evidently been hunting through his library for instances bearing on the point, and comes forward with a few brief sentences, selected most judiciously from the works of three well-known men, but unfortunately they do not assist him in the least degree, as neither of those authors would venture to make such a sweeping assertion as your correspondent has done.

When I look round me and see the splendid results achieved by practical men in every branch of gardening, who use water such as I have described for eight months in the year, I require no further proofs, from authorities great or small. When I can see better produce grown by the advocates of soft water, then, and only then, shall I be ready to change my line of front. This question is one of the small number of "old-fashioned ideas" dying a hard death in the ranks of the garden-

ing community.

It would be interesting to know how many gardeners have had to rely on tap or well water throughout the past summer, and equally valuable to know how their plants are looking in consequence. Mr. Molyneux has evidently been using it with good results, like hundreds of other growers. Where a man's living depends on the value of the crop he produces he is bound to look about him pretty smartly in these days for the means of achieving the best results. As a body the market-growing community produce as good crops with tap or well water as, I think, Mr. Dunn has seen. In his zeal to make a showy case for his hobby he has allowed himself to be carried past the post of modern teaching and practice.-J. B. R.

ON AN EXPERIMENT WITH SHANKING GRAPES.

My communication (page 238) coupled with the Editor's footnote appended thereto, has had precisely the effect I most desired to seenamely, the commencement of a controversy that must be both interesting and profitable to Grape-growers, successful or otherwise. Controversies of any kind are not much in my line, but I will endeavour to reply to your correspondents to the best of my ability, merely premising that what I have to say is intended to apply to summer or midseason

(page 262) idea of thinning the bunches on every other Vine is identical with my own, but I was over-ruled in the matter, and in this instance I do not regret it. The fiat went forth that by this experiment the Vines were to be "mended or ended." If "R. P." refers to my notes he will see I used the word "borders" in connection with

the use of liquid manure.

I do not agree with "F. G." (page 263) in excluding the sun's rays from the Vine border during the summer months. Mr. H. W. Ward's note of interrogation attached to the word "magnificent" on the same page is not surprising, but to judge by the sturdy nut-brown canes and large stout leaves, the Vines have to all appearance been equal to the occasion. I have all along practised the system Mr. Ward advocates of bringing up new rods in place of the old ones with their long barren spurs.

In reply to Mr. Roberts (page 263), the drainage was rectified at the time the roots were lifted. Mr. S. T. Wright's views on the same page

coincide with my own as to the use of manures.

Mr. Abbey's exhaustive article on page 292 is in some respects a revelation to me, but beyond stating that the variety left unthinned last year was Black Hamburgh, I will only say that I am a gainer by

its perusal. Mr. Young's and Mr. Stephen Castle's notes (page 315) afford additional proof of the complexity of this subject.

Your correspondents seem to be unanimously agreed that I am putting forth the theory of non-thinning as a universal remedy for shanking in Grapes. Nothing could be further from my mind. What I said was, that I had no doubt that "dispensing altogether with the scissors had something to do with the result." My meaning was this. I took into consideration the enfeebled state of the Vine roots through want of proper nourishment, and it occurred to me that if I spared them the innumerable wounds caused by thinning the bunches it might perhaps afford them some relief. This idea may appear to some readers rather far-fetched, but I think this year's crop proves to demonstration that my surmise was a correct one.

To sum up, it has been abundantly shown in these columns that shanking exists from a variety of causes, from impoverished borders as well as those in which the roots are overfed. Knowing as I do the past history of the Vines under my charge, and knowing also that they have not had to contend with such contributory causes as injudicious summer pruning, bad ventilating, and other evils, I can only reiterate my previously expressed opinion that in this case "poverty at the root is the chief cause of shanking." — Thos. RICHARDSON, The Gardens, Simonside

Hall, South Shields.

NEPENTHES AT CHELSEA.

PERHAPS in no other nursery in England is there such an excellent and complete collection of Pitcher plants as at Messrs. J. Veitch & Sons', Royal Exotic Nursery, Chelsea. As with other things of which this firm make a speciality, the plants under the charge of Mr. Tivey are admirably grown. They always look clean and healthy, and the structure devoted to them is one of the most attractive in the nursery. It has always been strange to me that Nepenthes are not more largely grown in private places, where they would unquestionably enhance the beauty of a stove. True, some cultivators experience a difficulty in inducing the plants to pitcher, but this is often the fault of the growers. If the plants are allowed to grow rampant they will not form the pitchers, but if they are carefully attended and the luxuriant leaders judiciously pinched, pitchers will be formed in abundance, always providing the plants have had proper treatment in other ways.

They are very easily grown, the temperature maintained in the generality of plant stoves being exactly suited to the requirements of Nepenthes. Sphagnum moss and good fibrous peat form the necessary compost, and these with water rationally applied are all that is required in the cultivation of Pitcher plants, and the popular name will no longer appear a misnomer, as it at present does, when one sees the miserable specimens, destitute of pitchers, growing, or rather existing, in many stoves throughout the country. It is, I should say, practically certain that if Nepenthes can be cultivated so well at Chelsea, where the densest and blackest of the London fogs are experienced, and which it is acknowledged have such an enervating effect on most plants, that they could be grown at least equally as well in the country, where they would have the manifold advantages found in pure air, and to which all

plants are, like human beings, so thoroughly partial.

It will doubtless be interesting to many readers to know what species and varieties are now looking their best. I will therefore enumerate a few of those which I considered most worthy of mention. The one figured so excellently on page 315 of the last issue of the Journal, N. mixta, is a beautiful hybrid with large striking pitchers, several of which measured 10 inches in length. The grand N. Mastersiana must still be placed in any eollection, for with scarcely an exception it is the freest growing variety known. The pitchers are also of good size and of a rich deep red colour. N. Hookeriana earries pitchers of an entirely different shape to the two previously mentioned varieties, they being different shape to the two previously mentioned varieties, they being short and very broad. This variety, besides having fine bold pitchers, has the merit of retaining them longer than any other, the pitchers frequently hanging for twelve months, and being at the end of that time still in good condition, though deficient in eolouration. N. Northiana is a handsome variety with bold and effective pitchers measuring 8 inehes long and 9 inches in circumference. The ground colour of this hybrid is a greenish red, which is spotted and streaked with crimson. A plant of N. Chelsoni presented an extraordinary appearance. This example was in an 8-inch basket, and was carrying no less than twenty-five fully developed pitchers, amongst which were several 7 inches long, and as many or more in girth. This was the only variety I could see which rivalled N. Masteriana in freedom of pitchering. To N. Rafflesiana belongs the honour of bearing the largest pitchers, many of which are capable of holding nearly a pint of water. This kind also is free, and the plants present a really imposing sight, as I am confident everyone would admit on seeing them.

N. Amesiana is a variety of much merit, with chocolate red pitchers of great substance, many being 8 inches long and 11 round. N. Burkei excellens is a handsome species which was figured at page 161 of the Journal for August 21st, 1890. The pitchers, in many instances, measured from 8 to 10 inches in length. A charming hybrid is found in N. Dicksoniana. The predominating colour is light green, which is profusely spotted with bright reddish crimson. The average length of the pitchers measured on plants of N. Dicksoniana was 9 inches, by which an idea may readily be gained as to the striking nature of the plant. The blood-red pitchers of N. Curtisi superba are very beautiful, and are streaked with greenish yellow markings, which produce a unique

and at the same time pleasing effect.

Those mentioned are well worthy of cultivation, but let me recommend admirers of these plants to go and judge for themselves. They will then be better able to form an idea of what they can do in their own stoves with the aid of perseverance, and a little of that intelligence which they lavish so freely on such plants as Chrysanthemums and Roses.—H.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

ANNUAL DINNER.

THE members of the above Society held their seventh anniversary dinner at the Cannon Street Hotel, E.C., on Tuesday evening, Oct. 10th. P. C. M. Veitch, Esq., occupied the chair, and there was a large attendance, upwards of a hundred gentlemen sitting down to the tables. Amongst others present were H. J. Veitch, Esq., N. N. Sherwood, Esq., Clarence Smith, Esq., M.P., H. Rivers, Esq., Messrs. Arnold Moss, G. J. Ingram, W. Marshall, P. Barr, H. Cannell, J. Cheal, J. Hudson, B. Wynne, G. W. Cummins, N. Cole, J. R. Chard, W. Collins, Secretary, and numerous other horticulturists and their friends.

Mr. P. C. M. Veitch, after the customary loyal toasts, gave that of "The United Horticultural Benevolent and Provident Society," coupled with the name of N. N. Sherwood, Esq. In his opening remarks the Chairman said he looked upon it as a great honour in being asked to preside that night. He had been brought up amongst horticulturists, and took great interest in gardening, and especially in this Society. One always admired the benevolent institutions, but there was something particularly attractive in this, as a man might not only provide for himself in case of sickness, but for his wife and family. (Hear, hear). A great deal had been said of late about old age pensions, and many would agree with such a scheme if nearly all the money invested was not eaten up by the management. This Society was the right and true system of old age pension. (Hear, hear). He would ask all gardeners present, and others, to bring the Society and its good work before their young men. It was the proper thing for gardeners to join whilst they were young. As regards the progress they had made, it was gratifying to know that whilst in 1877 there were only 109 members, there were now 500 on the books. This was largely due to the annual dinners. There were now more than £8000 invested, and these figures would show that the Society was in a very satisfactory condition. After referring to the small expenses connected with the Society, the Chairman observed that the Convalescent Fund, which was started about two years ago by Mr. Sherwood, was not, he was sorry to say, in a very strong condition. Every member should subscribe as much as possible to it. The Benevolent Fund was satisfactory, but he hoped it would not entrench upon the older institutions. The motto of the Society was, "Union is strength," and he would conclude by wishing them more power. (Cheers.)

Mr. N. N. Sherwood in responding, observed that he thoroughly agreed with all that the Chairman had said. He thought that if the objects of this Society were better known they would have three times as many members. The Society filled a most important link between the other two gardening charities. It teaches men to be thrifty, and it was the duty of every man to save something. As regards the Convalescent Fund he might ask could not gardeners put the matter before their employers, and urge them to do something towards it? In order to celebrate the jubilee of the firm with which he was connected (Messrs. Hurst & Co) he would add £50 to the Convalescent Fund, and he hoped

it would not be allowed to dwindle out (applause.)

Mr. J. Hudson proposed the "Honorary and Life Members," and briefly remarked that on the previous evening they had opened a new departure in this respect by electing a lady as an honorary member.

Clarence Smith, Esq., M.P., and W. Marshall, Esq., responded, the first named gentleman remarking that although there as a visitor on that occasion, he hoped to be elected an honorary member before next

Mr. H. J. Veitch briefly gave "The Officers of the Society," coupled with the names of Messrs. J. Wheeler, W. Collins, and J. Hudson, who subsequently responded. Mr. Veitch remarked that he should have pleasure in subscribing 5 guineas to the convalescent, and a similar sum to the management fund.

Mr. Arnold Moss proposed "The Chairman," to which Mr. P. C. M.

Veitch briefly responded.

The tables were tastefully decorated with flowers by Mr. J. R. Chard and others, and some excellent fruit was kindly given by various friends. The surplus fruit was presented to the inmates of Guy's Hospital. The musical arrangements were under the direction of Mr. Herbert Schartau.

THE SALISBURY DAHLIAS AT HOME.

HAVING seen blooms of the various sections of the Dahlias in Messrs. Keynes, Williams & Co.'s first prize stands at horticultural exhibitions in various parts of the country within the last few weeks, a natural wish to see these flowers "at home" was realised on the 11th ult., when I was fortunate enough to find Mr. W. H. Williams "at home" also. Under his courteous and able guidance a move was at once made in the direction of the Dahlia ground. Here we found the veteran grower and able manager of the Castle Street Nurseries (Mr. John Wyatt), and one of his skilled assistants, creating havoc in a plantation of seedling Dahlias, only here and there a "plant of promise" being left standing for growing another year.

But in allowing the eye to wander from this somewhat desolating

scene in another direction what a floral picture presented itself! Here 1600 large plants, including all sections of the Dablia, and in grand flower, met the gaze and made a display impression on the mind that will not easily be forgotten. In front were rows of the show and fancy kinds, the blooms being of great depth and breadth and fine in form. Conspicuous among the show varieties were the white-tipped, crimsonedpetalled Maid of Kent, the pure white Gloire de Lyon, and the bright, scarlet coloured Walter H. Williams. Prominent among the Pompons was Leila, reddish buff tipped with white, and further on row after row of the Cactus Dahlia, comprising pretty well every shade of colour between white and crimson, many of the blooms of individual varieties being a combination of pleasing hues. The most striking blooms observed among this section of the Dahlia were Lady Penzance, soft yellow (not yet in commerce); Dawn, lemon, deepening to orange; Countess of Radnor; Kaiserin, sulphur yellow, the outer florets being tinged with lemon; Gloriosa, an improvement on Juarezi in size, colour (rich crimson) and form of flower; Countess of Pembroke, delicate lilac, a very attractive variety; Kynerith, rich vermilion; Dr. Masters, blush white tinted with lilac; Bertha Mawley, cochineal colour, a grand flower; Duke of Clarence, deep crimson with scarlet shading towards the top of the petals; Black Prince, flowers very large and velvety blackish maroon in colour; Delicata, light salmon at base of florets gradually shading off to a delicate pink; and St.

Katherine, soft reddish amber, a fine variety.

I may be permitted to say, by way of showing the amount of labour that was involved in watering the Dahlias at Messrs. Keynes' during the past four or five months, that each of the 1600 plants grown received 20 gallons of water every week—equal 32,000 gallons per week; the ground between the rows and plants being also heavily mulched with substantial manure.—W. H. W.

ROYAL AQUARIUM.

OCTOBER 11TH, 12TH, AND 13TH.

An Exhibition of Chrysanthemums, Begonias, and other flowers opened at the Royal Aquarium, Westminster, on the 11th inst., and will continue the two following days. Chrysanthemums were not so extensively shown as many expected, but the flowers were fairly good.

Fruit was excellent, and some vegetables were staged.

The leading class in the cut bloom section was for twenty-four Japanese, and there were five competitors. Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley Cottage, Croydon, was first with a stand of grand blooms. The best flowers were Colonel W. B. Smith, John Shrimpton, W. Tricker, Mrs. C. H. Payne, President Borel, Sunflower, Mons. Bernard. The second prize went to Mr. C. Cox, gardener to John Trotter, Esq., Brickendon Grange, Hertford; and Mr. W. Higgs, gardener to J. B. Hankey, Esq., Fetcham Park, Leatherhead, was third. There were six competitors in the class for twelve Japanese blooms, and after a close fight Mr. W. Collins, Ponsbourne Park, Hertford, secured the first prize. The flowers were fresh and even, the best being R. C. Kingston, Sunflower, Avalanche, William Holmes, and Stanstead White. Mr. T. Wilkins, Inwood House, Blandford, was second; and Mr. E. Rowbottom, The Gardens, The Priory, Hornsey, N., third. Mr. Rowbottom, however, was first with a dozen incurved blooms, the best of which were Mons. R. Bahuant, Mrs. Dixon, Baron Hirsch, and Refulgens. The second prize was secured by Mr. J. Agate, Havant, Hants. Messrs. W. Collins and J. Agate divided the prizes for six incurved

Mr. E. Tickner, gardener to J. Watney, Esq., Reigate, was given the first prize for twelve Japanese blooms. There was no other competitor in this class. The same exhibitor secured the leading prize for six blooms of Japanesc. For six blooms of new varieties, Mr. F. Agate was awarded a silver medal. The varieties shown were Princess May, Mrs. Fowler, Miss Watson, Charles Davis, Duchess of Devonshire, and Beauty of Exmouth. Miss Debenham was first for twelve bunches of Pompons in the amateurs' class; and Mr. D. B. Crane, Highgate, secured prizes for these Chrysanthemums. Mr. T. Osman, Ottershaw Park, was first for twelve Japanese blooms. The prizes for groups of Chrysanthemums went to Messrs. Davis and H. J. Jones. Mr. Jones also had a collection of cut blooms, not for competition.

For a table of bouquets, wreaths, and sprays composed of Chrysanthemums, Mr. J. R. Chard, Stoke Newington, was first with a charming arrangement. Mr. Chard also secured the first prize for three vases arranged with foliage and flowers in a graceful manner. Mr. F. W. Seale, Vine Nurseries, Sevenoaks, was second, and Mr. D. B. Crane, Highgate, third. Extra prizes went to Mr. A. Minden, gardener to Dr. Paul, Camberwell, S.E., and Mr. W. Molc, Hemel Hempstead, Herts.

Miscellaneous exhibits were numerous. Messrs. J. Laing & Sons,

Forest Hill, S.E., arranged a charming group of Tuberous Begonias with a background of Palms. Mr. T. S. Ware, Tottenham, sent a hamper of Aster grandiflora, blooms of new Dahlias, and the pretty Mr. T. S. Ware, Tottenham, sent a Nerine elegans alba which was certificated at the Drill Hall on the previous day. Mr. W. J. Godfrey, The Nurseries, Exmouth, staged a dozen splendid blooms of Beauty of Exmouth Chrysanthemum, proving, as remarked last year, that it is one of the finest varieties in cultivation. The same exhibitor had blooms of several new varietics, including Charles Davis, Duchess of Devonshire, Eda Prass, and Madame E. Rey. with others were placed before the Floral Committee for certificates, but when our reporter left no awards other than in the competitive classes had been made. Messrs. Perkins & Sons, Coventry, had blooms of Dahlias Matchless, Purple Prince, and Mr. F. W. Seale sent Dahlias Daisy Seale and Roy Douglas Seale. Mr. W. Cross, Green Cottage, Sidmouth, staged two plants of a dwarf growing dark coloured seedling Japanese Chrysanthemum, and Mr. J. Haws, Clapton, N.E, had watering cans in variety. Mr. J. H. Witty, Nunhead Cemetery, had a group of Chrysanthemums, and Mr. W. Wells, Earlswood Nursery, sent some cut blooms. Mr. S. Mortimer, Swiss Nursery, Farnham, showed Dahlias, Stephanotis, and Tomatoes. Messrs. Pitcher and Manda sent a stand of new Chrysanthemums, as also did Mr. R. Owen, Maidenhead. Messrs. W. Edwards & Son, Sherwood, Nottingham, exhibited examples of their new "Edwardian" vases, which are admirably adapted for all kinds of floral decoration when filled with Ferns.

As before mentioned, fruit was largely shown. Mr. J. Watkins, Withington, Hereford, had a collection of Apples and Pears; and Mr. C. C. Tudway, The Cedars, Wells, sent a dish of splendid Doyenne du Comice Pears. Mr. J. Masterson, Shipston-on-Stour, sent two dishes of Pitmaston Duchess Pears; Mr. T. Perkins, Thornham Hall, Suffolk, Hero of Lockinge Melon; and Mrs. Barret, Renfrew Villa, South Ealing, some stewing Pears. Messrs. J. Laing & Sons, Forest Hill, had a fine collection of Apples and Pears. Messrs. H. Cannell & Sons, Swanley, staged Apples and a splendid collection of vegetables, also some Begonia blooms. Messrs. J. Cheal & Sons, Crawley, sent Apples and Pears, and some very fine Dahlias tastefully arranged.

The prizes offered by Messrs. Sutton & Sons for vegetables brought forth a fair competition. Mr. T. Wilkins secured the leading prizes for Cauliflower and Beet; Mr. C. Osman, Sutton, being second in each case. Mr. C. Waite was first for Carrots, Leeks, Onions, Celery, and Tomatoes. The other prizewinners in various classes were Messrs. T. Wilkins, S. T.

Cook, and D. M. Hoyler.

HARDY FRUIT GARDEN.

Lifting Fruit Trees .- One of the surest methods of inducing fruitfulness in young trees is to lift and replant. This checks strong growth and keeps the roots of a fibrous character, which favours sturdy, short-jointed growth. In some places Peaches, Nectarines, Apricots, and Plums make late growth which does not ripen well. Lifting, when the trees are not too large, will check the late growth, and benefit the wood already made by encouraging it to ripen earlier, also preventing strong growth the following season. With the fruits mentioned the work of lifting may be proceeded with early in October. It should be done quickly, not on any account exposing the roots for a lengthened period to dry air. Do not commence too close to the stems, as it is important that all the fibrous roots be preserved and kept moist. Sever the long and strong roots found, trimming them smoothly and leaving no jagged ends. Replant a little higher than formerly, and bring some of the fibrous roots nearer the surface, affording all good soil to ramify in, compressing it firmly about them. Mulch the surface and a foot beyond the space the roots extend with half-decayed manure. Previously to this water the trees to maintain the foliage fresh, applying shade also for a time if the leaves flag, and syringe regularly every dry day. these precautions lifted trees with a large proportion of foliage will soon make fresh roots and be much improved by the slight check given.

Stations for Planting Fruit Trees.—Where it is not possible to prepare a large extent of ground by digging or trenching it all over, prepared stations may be formed at the required distances. They should be 6 feet square, and hold 2 feet of good soil, resting on a gravelly, chalky, or stony subsoil, which insures perfect drainage. Land with a clavey, wet, and retentive subsoil will, in order to prevent the roots striking into an undesirable medium, causing strong unfruitful growth, require an artificial foundation of concrete, across which may be laid drain pipes connected with a main drain and outlet. The depth of the concrete should be 4 inches, over which and the drain pipes must be laid 6 to 9 inches of rubble made secure from being choked with soil by a

layer of turf grass side downwards.

Distances Between Stations.—The distances between stations must be guided chiefly by the fact whether the trees are on the free or restricted stocks, this being mostly important with Apples and Pears, which, in the case of large orchard standards grown on free stocks, should be 24 to 30 feet apart. Plums and Cherries may be planted in stations formed at similar distances. Dwarf and standard-trained trees for walls may be for Apricots, Plums, Peaches, Nectarines, and Cherries 15 to 20 feet asunder; while Pears on Pear stocks should be 20 feet, and on Quince stocks 12 feet apart. Horizontally trained trees for espaliers and walls ought to be Apples on Crab stocks, Pears on Pear stocks, and Plums 20 feet apart; for Apples on the Paradise, and Pears on Quince stocks 12 feet suffices. Bushes and pyramids on free stocks should be 8 to 10 feet apart, 2 feet less when root-pruned. Apples on Paradise stocks, Pears on the Quince 6 feet apart.

Root-pruning.—When fruit trees grown on the various restrictive systems assume year after year a chronic state of unfruitfulness there is something wrong either with the roots or the methods of managing

the branches. Making too much wood in summer, before any attempt is made by the cultivator to restrain the natural vigour within proper bounds, is usually the cause of destroying the necessary balance between root and branch. Summer pruning does much to restrain the growth of wood and concentrate the sap in the fruit-bearing spurs, as well as in the formation of buds that will eventually be fruiting spurs. But sometimes, owing to the excessive vigour of strong roots, correct pruning and branch management are not sufficiently capable of sustaining trees in a permanent bearing condition. Root-pruning then becomes absolutely The production of a large amount of gross wood and correnecessary. spondingly ample area of leafage has a powerful effect on the roots, which, as a rule, when receiving extraordinary stimulus, descend perpendicularly. In doing so, especially in rich ground, they become very strong. The same result also occurs in a moist subsoil. The results then are coarse, thick roots followed naturally in the growing season by gross watery wood.

Mulching Fruit Trees. — While the ground is comparatively warm and the roots unusually active there is no better time than the present to assist weakly trees. The benefits in some cases may not be apparent until next season, when it will be visible in stronger growth. Trees with abundance of fruit buds require some assistance, in order that the bulk of these may become plump and prominent before active movement of the sap ceases. A mulch of rich manure over the roots is of material assistance now, the virtues contained in it being washed down to the roots and stored in the soil for future use; the residue left

can be raked off in the spring for the sun to warm the soil.

Top-dressing Peaches and Nectarines.—Old trees will be greatly benefited by having the loose surface soil pared off down to the roots, being careful not to injure the fibres, and a dressing of fresh compost supplied chiefly composed of turfy loam, mixed with some calcareous matter, such as pulverised lime rubble, a little manure, and charcoal, spreading it over the roots as far as the latter extend, compressing it firm, and finishing with a light mulch of short manure.

FRUIT FORCING.

Pines.—Young Plants.—Arrange these so that they will obtain the fullest benefit of light and air. Make an inspection of the plants about once a week, and when water is needed apply it copiously at about the same temperature as the bed. Ventilate freely when the external conditions are favourable, paying particular attention to this in the early part of the day. As the sun heat declines a corresponding diminution of temperature must take place at night until it reaches the winter standard of 55° to 60°, and 65° in the daytime by artificial means.

Plants to Fruit Early.—Queens are the best for this purpose, but to insure their starting into fruit with certainty they should be given a period of comparative rest after making a good growth. Plants intended to show fruit early in the year ought to be kept in a temperature of about 65° in the daytime by artificial means, 60° at night, ventilating at 70°, closing at that temperature, and allowing the bottom heat to fall to 70°. Water the plants only when necessary, not, however, permitting them to become so dry at the roots as to cause limpness of the foliage.

Plants Showing Fruit.—Any plants now showing fruit will be valuable, as it will come in when it is scarce, therefore afford such plants the best position in the house. Maintain a temperature in this department of 70° at night, 75° artificially by day, up to 85° or 90° with sun, closing at 85°, sprinkling the pathways when their surfaces become dry, and sprinkle the plants occasionally on fine afternoons. The bottom heat should be kept steady at 85° to 90°. Examine the plants about once a week for watering, and if any require it afford a copious supply of clear liquid manure at about the same temperature as the beds. Particular care must be taken not to over-water, as that has a tendency to cause the fruit to become black at the centre, which affects its keeping.

Peaches and Nectarines.—Earliest House. — The trees in the earliest house must now be pruned, and everything put in proper order for a fresh start. If the growths have been kept rather thin, and care taken to equalise the vigour, there will be little need for the knife. Any weak wood may be cut out in favour of sturdy and well ripened, shortening leading growths, so as to originate shoots for furnishing the trees. Where too crowded the bearing shoots may be thinned. Severe winter pruning is undesirable, as it generally results in spasmodic and sappy growth the following year. Untie the branches from the trellis, cleanse the house thoroughly, and dress the trees with an approved insecticide before securing them to the trellis. Allow plenty of space in the ligatures for the swelling of the branches. Remove the surface soil down to the roots, and supply a dressing 2 inches thick of fresh turfy loam, with an 8-inch potful of steamed bonemeal and a similar quantity of wood ashes to every large barrowload of loam. If wood ashes cannot be bad use half the quantity of kainit. Make firm, and follow with a good watering if the lights are fixed. The outside border should be dressed in a similar manner. The roof lights if removed may remain off until bad weather sets in, otherwise ventilate to the fullest extent.

Second Early House.—The trees to be started at the new year or soon afterwards will now have all the foliage down, and it is best to prune and dress them, also cleanse the house without delay. If the trees have been properly managed there will be little wood to cut out. But it will be necessary to look them over and remove any useless parts having escaped attention. Any shoots too long may be cut back to a triple bud or a wood bud, making sure of the latter whether the bud be a double or triple or single one, leaving sufficient wood for securing a

crop. Shoots 12 inches length or under must not be shortened, nor need those that are very much longer. Leaving too much wood weakens the trees in flowering, and there is not space for training-in the necessary growths for future bearing to insure their thorough exposure to light and air. Admit all the air possible at all times. If the roof lights are off do not replace them until the time arrives for closing the house. Where the lights are fixed avoid permitting the borders to become too dry, which is more pernicious than a wet soil at any time.

Midseason Houses. — The foliage in these will be approaching maturity, but there must not be any attempt at its forcible removal, though the falling of the leaves may be assisted by lightly brushing the trees with a broom. The lights should be kept open day and night, except when frost prevails, for it is not desirable to cause the sudden collapse of the foliage through freezing. When the leaves are all down the roof lights may be removed. This will ensure complete rest and the even and well moistening of the soil. If any lifting or root-pruning is intended these operations should be attended to as soon as the wood becomes firm and the buds developed, but before the leaves have all fallen, as there is then a better chance of fresh roots being formed than at a later period.

Late Houses.—The fruit in these structures has ripened quite a fortnight to three weeks earlier than usual, and there is now a scarcity of fruit in many places, though some still have good fruit through ventilating freely in the summer, even taking off the roof lights in broiling weather. The wood that has borne fruit should be cut out to the successional growths at the base, unless they are extensions. Trees growing too luxuriantly and late should have a trench taken out at such distance from the stem as will check their vigour and cause the buds to become plump. Such trees should be lifted as soon as the wood is sufficiently ripened. It should be done with dispatch, all the materials being in readiness. See to the drainage; if defective make it thoroughly efficient. Shorten back any strong roots, and bring any that are deep nearer the surface, making the compost firm. Good loam, rather strong, with an admixture of one-sixth of old mortar rubbish forms a suitable compost. If the soil be light add a fourth of clayey marl, and if very strong a similar proportion of road scrapings. Manure is preferably given at the surface. Give a good watering after lifting and completing the operations, and the roots will soon become established in the fresh material. Trees judiciously treated at the roots whilst they have some foliage seldom fail to set and stone the fruit satisfactorily the succeeding year. Any borders in a sodden and sour state at the surface may have a dressing of quicklime quite an inch thick, mixing it with the soil as deeply as the roots allow without much disturbance, and this will effect some improvement.

Cucumbers.—Plants in bearing require looking over not less than once a week, removing any bad leaves and exhausted growths, trainingin young shoots, pinching out their points one or two joints beyond the show for fruit, avoiding crowding and overcropping. Maintain a night temperature of 65° to 70°, 70° to 75° by day, advancing to 80° or 85° with sun, closing early, so as to rise 5° to 10°, advantage being taken of favourable opportunities to admit a little air, yet avoid drying currents and cold draughts. The floors should be sprinkled with water about 8 A.M. and 4 P M. respectively, dispensing syringing the plants except on fine days, when a light bedewing may be given at closing time. Reduce the supply of water at the roots, but not to cause flagging, and encourage surface roots by an occasional light dressing of loam and sweetened horse droppings. Keep the glass clean and the foliage rather thin, so as to secure thoroughly solidified growth.

THE FLOWER GARDEN.

Carnations and Picotees.—Layering has been a very successful operation in spite of the dryness of the season, and since a showery period has set in the roots have increased rapidly. No time should be lost in detaching these rooted layers from the parent plants, all being lifted with a small ball of soil about the roots. In some districts it is a good plan to place some of these young plants in 3-inch or slightly larger pots, using fresh fibrous loam, with a little old Mushroom bed manure and sharp sand added. If these are kept near the glass in dry frames or pits, given air freely when the weather permits, and further protected from severe frosts, very sturdy plants will be available for planting out next spring. Some of the strongest layered plants are flowering freely, and these might well be lifted and placed in pots that will hold them comfortably, a good succession of flowers being had under glass accordingly. The early raised plants of Marguerite Carnations are also flowering exceptionally well in the open borders, and something should be done to protect them. Span-roofed or other deep frames freely ventilated would prolong their beauty considerably, or if plants have not been kept in 6-inch pots, the best of those in beds might well be lifted, potted, and placed in a greenhouse to finish flowering.

Forming Fresh Beds.—Seedlings ought ere this to have been planted out, but the layered plants have not suffered from their long connection with the parent plants. No time, however, should be lost in completing the planting of all not placed in small pots. Let them have the benent of some fresh loamy soil, old Mushro m bed or other short manure, and road grit. They thrive best in slightly raised beds, the latter being about 6 feet wide, with 1-foot alleys between. Make the soil rather firm about the roots. Slugs must be trapped, as these quickly spoil the plants. A mulching of old Mushroom bed manure, leaf soil, or tanners' decayed bark acts beneficially, and in particular prevents frosts upheaving the ground and loosening the plants to an injurious extent.

Pinks.—Cuttings of Pinks are slow in rooting, especially where no bottom heat is afforded. At the present time they may present a sickly appearance, but will yet develop into neat plants by next spring. Any that are strongly rooted and hardened may be at once put out into raised beds, much as advised in the case of Carnations, only less room should be allowed—a distance of 9 inches apart each way suiting them well. The finest flowers are had from young plants, and a fresh bed ought to be formed every year. No cuttings having been rooted, the old fashioned plan of pulling healthy plants to pieces and replanting these should be adopted. These divisions will have rather long stems, some being furnished with roots and others not. All should be planted rather deeply or well up to the tops.

Pansies and Violas.—If neat plants raised from seed are transplanted to raised beds a good early display of flowers will most probably be forthcoming next spring. Autumn-raised plants should be kept under glass, and quite cool till the spring. Both Pansies and Violas have stood the dry season rather better than anticipated, and are now forming young shoots freely. It is these latter that make the best cuttings, though the flowerless tops will also root readily, and push up fresh growths from their base. No bottom heat is needed for either. Place a frame or frames on bricks, half fill with old heating material, making it quite solid, and on this dispose a layer 4 inches deep of soil, finishing off with a good surfacing of fine sandy compost, a little sand being sprinkled over this. Shorten the cuttings to about 3 inches in length, and insert them 3 inches apart all over the bed. Give a gentle watering, and keep the frame close and shaded from bright sunshine till the cuttings are rooted, after which abundance of air should be admitted.

Calceolarias.—Cuttings are late this season, but where the old plants were kept alive are becoming fairly plentiful. Now is a good time to attend to the propagation of these. If many plants are required next summer, prepare a suitable frame for the cuttings. Mulch as advised in the case of Violas, while hand-lights or shallow boxes may be used for smaller numbers. Give the preference to short-jointed moderately firm shoots, cutting these just below the third joint and trimming off the lower pair of leaves. Do not allow them to flag badly, but dibble them out quickly just clear of each other. See that the base of the cuttings rest on the bottom of the holes made with the dibber and fix them well, as otherwise they will not strike roots. Water, put on the lights, and shade from bright sunshine. They will require more protection during the winter than Violas, but if not unduly coddled will not be injured by an ordinarily severe frost.

APIARIAN NOTES.

PRACTICAL HINTS FOR BEGINNERS. (Continued from page 321.)

BEYOND raising queens at the proper season from full strength hives, and discarding very small queens, the bee-keeper has no control of improving or selecting the best. Medium-sized queens are often the most prolific and the longest lived, and as a rule are fertilised at an earlier date than extra large queens, the latter very often coming to grief through failing to mate, which sometimes takes place within twenty days from the deposition of the egg that produced her, and occasionally as late as fifteen weeks. I have had several cases of the latter. As previously stated, queens sometimes deposit eggs almost immediately after birth. Imperfect queens do that, but in every case of the kind the progeny are drones, and the mother remains a confirmed drone breeder. In the other cases, the queen in an unfertilised state produces drones only; but when mated, and then becomes a fertile queen, she breeds both workers and drones.

Swarming and the control of it depends very much upon the state, fertility and non-fertility of the queen. During the early spring a hive having a fertilised but non-egg-producing queen, swarms out entirely, leaving behind it anotherwise well-stocked hive. Incipient disease has apparently the same effect, as well as under-fed hives. Premature swarming takes place when a duality of queens are in a hive, either from a stranger entering that belonging to another hive, or when one or more has been reared by the bees at too early a date. Sometimes a similar result occurs when the queen regnant shows signs of collapsing, but at others when no reason can be assigned a queen caged contiguous to the bees on the top of a hive causes swarming, and this is the reason we destroyed one (the old one) When near the of the two queens in the one hive system. honey flow there is no advantage gained by allowing both to A very prolific queen having too little breeding space, and a much less prolific one having too much, are both causes of swarming.

The prevention of swarming is best effected by deposing the queen regnant, introducing a youthful fertilised one, giving

additional breeding space equal to receiving 5000 eggs daily; but this will also have its limit. A lengthened period of honey gathering as occurs on the moors may upset all calculations. Super room will not tend to prevent swarming; it must be breeding room, while after queen cells with eggs or larvæ are being raised, nothing short of winter will prevent it. Bees always prepare for swarming eight to ten days beforehand. Destroying queen cells will not prevent it, especially during a honey flow, for immediately after their destruction the bees will raise others, even although a youthful and fertile or unfertilised one be safely introduced, which fully exposes the fallacy of "direct introduction of queens."

As a rule, the mother queen leaves with the first swarm, but there are many exceptions. If the prime swarm leaves before the tenth day after the commencement of the first queen cell, then the old queen is sure to be with the swarm. If delayed longer the old queen may be destroyed, and one or several young ones may accompany the swarm. In such cases the whole of the swarm, after being hived, may abscond. Whenever the bees are secured a piece of queen-excluder zinc should cover the entrance, which will, in some cases, prevent the loss of the bees and after swarming. The surest of all methods is to destroy all surplus queens and queen cells eight days after the issue of the first swarm, and at the same time remove or transfer to another hive all unsealed brood. I had several cases this year at the moors, where swarming was repeated five times in all its phases, and yet the old queen remained regnant during three of the times, which in all occupied seven weeks. In some instances the old fertile queen remained in the hive, and left with the third and fourth swarm respectively. In others, the young queens being fertilised at an early date, when there was, comparatively speaking, little breeding space, they soon filled it, and the raising of queens followed, then swarming. The most tantalising of all phases of swarming is when queens are preserved for weeks long after the expected time of the deposition of surplus queens. This year I experienced, in several cases, queens piping from three to six weeks after they had commenced to pipe. These are, no doubt, exceptional instances, but they occur oftener than most bee-keepers

Introducing alien queens sometimes bothers the beginner. To accomplish this safely the hive must be deprived of its queen regnant, making sure there is no other perfect or imperfect ones, known by the bees raising queen cells. After there are no unsealed brood the queen cells ought to be destroyed, leaving the bees without a chance of rearing one perfect or otherwise, when they will make a commotion towards evening. This is a sure indication that they are queenless and will accept a queen. Introduce her by caging first in a safety cage, which consists of two apartments, one for the queen and the other for the bees, separated from each other by a piece of wire cloth or perforated zinc, and covered with glass sliding in grooves. When the bees are willing to accept the alien queen they cluster loosely against and under her, and she will be active or adhering firmly to the zinc anxious to join the bees. The little slide in the end of the cage may then be drawn up and the work is done. If, on the other hand, the bees show a great desire to get to the queen they are not in a pacified state to receive her. A little experience soon teaches the beginner when to admit the union. So long as the bees show white necks they are too frenzied, and would in all probability kill the queen.

As a substitute for the safety cage, remove the lid, admit the bees to the crown of the hive, place the cage upon its edge, and cover with a bell-glass. Watch their proceedings, and when favourable remove the glass, lifting the wire cloth a little so that the bees can get at the candy. They will eat it and join peaceably with her, when in a day or so the encumbrances may be removed and the covering of the hive adjusted.

Hiving is sometimes as provoking to the beginner as it is interesting, as the bees when leaving the hive are not known by the bee-keeper where they will settle. I will in another chapter give some particulars forming the guidance of beginners.—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Secretary, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—Secretary, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—Secretary, Mr. A. F Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

TRADE CATALOGUES RECEIVED.

H. Cannell & Sons, Swanley, Kent.—Carnations, Picotees, Pinks, and New Chrysanthemums.

P. J. Loozmanse & Sons, Ondenbosch, Holland.—Ornamental and Forest Trees, &c.

M. Vigneron, A. Olivet, Orleans.—Roses.

W. Wells, The Earlswood Nurseries.—Chrysanthenums.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

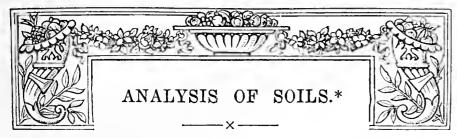

Poetry (*Planta*).—We do not know the book from which the laboured verse is taken, and if we did should decline giving it an advertisement in the form you appear to desire. Why did you not send your name and address? We do not desire any more anonymous inquiries of this nature.

Beet Seed (G. Craig).—The wholesale price of this, like other seeds, is governed by the supply, and it is not unlikely that the prices for many kinds will rule higher than usual this season. We cannot give the "average" prices of any kind of seeds. The information can only be had by consulting wholesale price lists over as many years as you wish the "average" to be based—three, five, ten, or twenty as may be thought desirable for your object.

Pansy Celtic Gem (Alex. Lister).—The yellow self Fancy Pansy bloom sent is of large size, rich gold colour, with an immense bronzy maroon blotch in the three lower petals, which are much rayed in the margin. It is a grand decorative variety, and if the blotch had been cleaner cut on the margin and the lower petal a little wider it would have been a very fine exhibition flower. We find that with the cooler autumnal weather some very fine Pansy blooms are now to be seen, and many such come under our notice. The flower in question of Celtic Gem is 3 inches in diameter.

Crinum capense (J. G.).—Presumably you did not see our reply in the issue for July 20th, page 66. The plant should have completed its growth now, and be fully exposed to every ray of sunshine possible, and have abundance of air. The supply of water should be gradually diminished until the plant can be kept dry, but not sufficiently dry to cause the thick fleshy roots to perish. By this treatment the plant will not be quite deciduous, but when grown in a warm position outside the whole of the foliage is invariably destroyed by frost. The Japanese Honeysuckle to which you refer is perfectly hardy, and may be planted in a sheltered place outside, where we have no doubt it will do better than in your conservatory. We have known this plant fail under glass by being kept more or less constantly growing. A season of rest is important to secure good growth and perfect health.

Original Testimonials (X. Y. Z.).—We conceive that while an employer receiving "generally addressed" testimonials would not be liable for their accidental loss or destruction (seeing that the holder should carefully guard his interest in them by sending copies), that employer cannot retain possession of originals after notice to return them to the owner. The entrusting of their carriage to the care of the post office is no evidence that the owner intended to part with them. So long as the original testimonials are in transmission within the unbroken envelope, the envelope and its contents belong to the addressee. After reading the testimonials he has a qualified right of possession as against everybody but the owner, to whom he must yield them on demand. The position is more clearly seen by supposing that the testimonials have been stolen from their rightful owner and sent to the addressee by an impostor. The mere fact of the impostor sending them through the post cannot confer an absolute right of possession to them on the addressee. He is then in the position of a holder of stolen or lost property, who has a mere qualified right of possession to the property, and which yields to the absolute right of the owner when he appears. The sender of original testimonials, by transmitting them through the post, no more parts with his ownership than by losing them, though he takes the risk of their becoming irrevocably lost or destroyed upon himself.

NALYSE the plants you require, see what they are composed A of, and then analyse your soil and see if these things are in it; if not, put them in. How simple, refreshingly simple, is it not? What a glorious discovery! Why, we can grow what we like, and where we like, and very nearly when we like. Why did not somebody think of this before?" These were something like my thoughts once upon a time. I was younger then and youth has its enthusiasm, its illusions, and afterwards its awakening. then I have found that matters do not always turn out as we think they ought. There is usually a hitch somewhere, sometimes two or three, and not seldom you begin to think there is nothing but hitches. Then a kink comes out, one of the hitches unravels, and you recommence with renewed energy; the next hitch straightens out, and the fever of enthusiasm once more possesses you, but you again find something has gone wrong, and sit down discouraged. There was a time when I thought I held the science of agriculture in the palm of my hand. A few attempts to put theory into practice convinced me that some of it was oozing out between my fingers, then I began to wonder if I had not a handful of disconnected facts to play with, and to-day I see that scientific farming only looms hazily and lazily in the distance.

Oh! these visions of the young enthusiast, how they mock our eager souls! I was going to analyse every field and register the composition of its soils, and would henceforth know exactly what it wanted, and this is how it worked, or rather did not work. I put my views earnestly before a typical farmer, who listened to them all with a patience I have often since wondered at. Then he said, "Umph; so you are another of 'em, are you? You're a clever young fellow, I daresay; but you see, I am an old farmer—so was my father, so was my grandfather, and so was his for anything I know. They learnt summat, lad, by a lifetime's work, and left their experiences to their sons, and I've got the benefit of it all and added my own, and you'll excuse me if I think I know more about farming than you do." He thought he was crushing me, but I said, "Do you admit that many great improvements have been made in agriculture, and especially in agricultural implements of late years?" "Oh yes!" said he, "that's right enough, we've made wonderful progress, lad." "Oh!" said I, "have you? Is there a single farmer, born such, that has not opposed every new thing with all his might? Has there ever been an improved implement brought out by a farmer? Has any one of these improvements been brought about by the farmers themselves? Have not every one of them been suggested and planned by outsiders—people not to the manner born?" This rather startled him, I think, but, of course, did not convince him. Eventually I induced an amateur farmer to let me experiment, and the success was encouraging; but a knock-down blow was in store for me. I had as I thought an exceedingly clever way of getting at the nature of the soil of a large field. I procured 16 or 32 half ounces of soil from as many parts of the field, and so obtained (I imagined) a fair sample of the whole. One day I had a sample of soil thus selected, and found it so full of iron that I said, "This soil will grow nothing at all," and was met with the reply, "Why, it is the best land we have." Still, I was right; I could only judge by the sample I had in hand, and it was

full of iron. A number of iron hoops had been left to fall to pieces on one part of the field, and from thence a good portion of my sample had been taken. I had already found out that to analyse soil for potash, lime, magnesia, phosphates, sulphates, nitrates, and chlorides involved eight different processes, and that to be fairly sure of the result each experiment had to be repeated twice or thrice, and that the farmer thought all this analysing could be paid for by "thanks" (I did not always get that), and when these iron hoops trundled up I just resigned that part of the business, and informed the farmers that if they wanted their soils analysing any more they must let their sons learn chemistry, or do it themselves, or pay from £5 to £10 for the work.

The foregoing indicates some of the difficulties of soil analysis. An accidental spill of some material in one part of the field may totally deceive the chemist. He can but report what he obtains from the sample sent him. That sample may give a fairly correct idea of the bulk, but there is at least an equal chance that it may not, and till our farmers are also chemists, and can spend their evenings and rainy days in slowly ascertaining the nature of their soil, it will be best and cheapest to analyse crops, see what they are built up of, and put those materials into the soil as manure in the proportions found in the crops, and take no care for what may or may not be in the soil already. Of course where large quantities of certain materials are known to be in the soil, such as lime or magnesia, those may be kept out of the manure; but where there is a doubt it is best to add all.

Nearly all plants and roots of plants contain phosphates, nitrates, sulphates, as well as soda, magnesia, potash and lime, and hence it may be argued (and fairly) that these materials must be available. Wheat, broadly speaking, analyses into 32 per cent. potash, 3 per cent. soda, 12 per cent. magnesia, 3 per cent. lime, 47 per cent. phosphates, 1 per cent. sulphates, and a little iron and silica. The straw of Wheat is more than half silica, that is flint, so that without silica you would get no Wheat at all, at least in its present state. As a creeping plant it might still flourish, and perhaps do better so. The things we do not know are vastly more numerous than those we do. It may be that the superabundance of silica alone causes the Wheat to rise upright, and that this is an interference with Nature's first intention. Wheat, Oats, and Barley are all evidently the same plant modified by circumstances and environment. What they may eventually modify into no one can guess. A crab is a lobster with its tail curved in and set fast, and Indian Corn as a variation of Wheat is less astonishing. We know not what anything may develop into. Chrysanthemum growers should see something of the vast latent power yet unused in Nature's storehouse. Who can say what a simple Buttercup could be made into by constant attention and abundant supplies of all plant food? Food can make a worker into a queen bee. What could it not do if we knew how to utilise it to best advantage? Environment is everything, the vast potentialities concealed in every speck of protoplasm are not to be measured by our stunted yard sticks. Potatoes analyse into about 60 per cent. potash, 1 per cent. soda, 3 per cent. lime, 5 per cent. magnesia, 1 per cent. iron, 17 per cent. phosphates, 6 per cent. sulphates; Mangel Wurzels into about 30 per cent. potash, 30 per cent. soda, 6 per cent. phosphates, and other things. It is clear enough from this that Potato manure does not want soda, and Mangel Wurzel manure wants large quantities of it. The composition of Strawberries is very like that of Mangel Wurzels, and I am not at all sure that if you were to try very hard and patiently you could not succeed in making a Mangel Wurzel into something very like a huge Strawberry. I am far from sure even now that Mangel Wurzel is not made into Strawberry jam.

By this time you have begun to see that the question is not one of remarkable simplicity. The secrets of Nature have to be wrung from her by force of patient investigation, experiments long continued and often repeated. We have learned that all vegetable products are composed of various chemicals. Most

^{*} Read by Mr. W. PICKARD at the Monthly Meeting of the Sheffield Chrysanthemum Society, held in the Society's meeting-room, Oct. 11th, 1893.

people associate chemicals with some sort of inferior goods made to represent, or as substitutes or adulterants for the proper article. It does not occur to them that there is not one thing in Nature, from the central grain of matter in the heart of this solid earth to the uttermost depths of the starlit universe, that is not a chemical, and subject to all the laws of chemistry. Every speck of dust is a mass of chemicals; the air you breathe is 76 parts nitrogen, 23 parts or ygen, and a little carbon. The air of Sheffield contains a great deal of carbon, but it is in the shape of a gas—carbonic acid. The carbon in smoke is carbon only—particles of charcoal, not carbonic acid. The water you drink is a chemical, hydrogen and oxygen. Table salt is chloride of sodium; the table, tablecloth, knives and forks, plates, and all you can put upon them, yourself, are all chemicals. It's no use saying, "No chemicals in mine." You must either live entirely on chemicals or die of hunger; there is nothing else in the whole universe. When you despise chemicals you despise your parents in more senses than one, and yourself also.

Let us get back. I said that we had learned that all vegetation was formed of various chemicals. These are mainly potash, soda, lime, magnesia, and iron, and their salts, nitrates, sulphates, chlorides, and phosphates, but we have yet to learn what or which of these salts are best for particular crops. When we have learned these facts we have to go deeper still, and find out if we can how the plants get hold of them. We say (as an easy way out of it) that these chemicals have to be dissolved in the water in the soil, and then the rootlets—the fine fibrillæ of the roots—absorb the liquid—drink them if you like; but we are only guessing. We cannot get down there with our microscope. Nature is too much for us. With all our skill and perseverance of inquiry and search we do not know with any sort of certainty whether plants absorb nitrogen (the nitrate maker) as nitrogen, as nitrates, or ammonia. You will perhaps have wondered why I have so far said nothing about ammonia, which we all know to be a good fertiliser. The reason is, I have included it in the term "nitrates." Ammonia is a nitrate of hydrogen. Every chemist who makes a discovery of a new compound, is or has been allowed to christen his invention by some name of his own choosing, so that we have many names for the same thing, which is confusing to the ordinary Chemists are often made fun of in those omniscient newspapers, who know so much and so little of everything, for using such long words. I am sorry any other kind were ever used, they simplify matters amazingly, in spite of the battalions of letters. Di, Nitro, Polyl, Amido, Phenyl, Amine look ferocious enough, but a chemist glancing at it knows pretty nearly how it is made, but if it had been called Manchester Blue or Sheffield Scarlet it would have conveyed no information.

I do not know what a Chrysanthemum analyses into, but I should say about 32 per cent. potash, 2 per cent. soda, 12 per cent. magnesia, 10 to 20 per cent. lime, 9 per cent. phosphates, 3 per cent. sulphates, 6 per cent. silica. This is the analysis of red Clover, which is such a lover of lime that if you apply this material heavily on almost any field you will get a crop of Clover, even if you have not put a single Clover seed into the soil. This brings on the tapis another of Nature's economies, or if you like it better we can (and without being paradoxical at all) call it one of Nature's extravagances. The soil is full of seeds. Nature has provided a thousand ways of transporting seeds of all kinds to all places. A whole series of very interesting papers might be written on the infinite variety of Nature's methods in this respect. Suffice for the present to say that all soils are more or less full of all kinds of seeds. Which of them comes up depends on the soil. Many kinds are there waiting opportunity—waiting, one may say, for the suitable partner; when that partner turns up, the orchestra strikes up the music of the spheres, and the waltz begins. When lime is used plenteously it destroys some seeds, paralyses others, but wakens the dormant Clover seed into joyous life. When the Black Forest in Germany was on fire years

ago the Fir trees were burnt to the ground, and the seeds and roots destroyed also. Beneath these lay the waiting Beech seeds, and up sprang a forest of Beech trees where formerly had been Fir trees.

(To be continued.)

MICHAELMAS DAISIES AT CHISWICK.

NOTWITHSTANDING that the perennial Asters, or Michaelmas Daisies, as they are popularly termed, have for many years been grown in gardens, their merits for a lengthy period were unrecognised. They were formerly cultivated, moreover, in a very haphazard manner, hybridised, and named perhaps indiscriminately, with the inevitable result that much confusion has existed regarding the nomenclature of the numerous species and varieties. To a certain extent this difficulty still remains, and it is the opinion of some authorities that it cannot be entirely overcome, but much good work in this direction was accomplished last year by the Sub-Committee appointed by the Royal Horticultural Society for the purpose of revising the nomenclature of this extensive genus. comprising this Committee found the species (of which there are something like 250 known to botanists), varieties, and hybrids, with their synonyms in a confused mass, but, thanks to their efforts, more order has been maintained, and when a choice collection of the best kinds is grown, as at Chiswick, it is possible to recognise the better forms and identify them with accuracy. Improvements, however, might still be effected in this matter, and the work of elimination so well begun could be carried on with advantage in trade circles. Were this accomplished systematically there would be less cause for complaint, now often heard, as to the "weediness" of Michaelmas Daisies, and instead of this they would occupy a foremost place amongst autumn-blooming plants.

Regarding the collection of Michaelmas Daisies in the gardens of the Royal Horticultural Society, it is perhaps the finest that may be found in any one garden. All the best cultivated forms have been gathered from the various sources in Britain, and being planted on a long border by themselves, an excellent opportunity for observing the distinctive characteristics of the respective species and varieties is thus afforded. A glance at these during the autumn will convince the most sceptical that the better perennial Asters are deserving of all that can be said in their favour. Here can be seen the type of any one particular species, and by its side the varieties or improved forms may be noticed. The most conspicuous improvements that have thus been effected are apparent to all, and those who observe keenly will see a distinction between the varieties that are grown. Some may be distinguished by the colour of their stems, and others it is possible to recognise by a broad or narrow, or squarrose or adpressed involucre, as well as the height, habit, and time of flowering. These characteristics are detailed in the descriptions of the best species and varieties drawn up by the Committee referred to, and published in the Journal of the Royal Horticultural Society, vol. xv., parts 2 and 3. In some parts of the border we find clumps of the taller growing species, some loose and graceful, others compact in habit, and close by are plants of the dwarf forms covered like the former with blossoms that sparkle brilliantly in the sinking sun of an autumn day. This year many of the perennial Asters flowered prematurely, as did numerous other plants, and on visiting the collection at Chiswick last week the writer found the majority of the earlier kinds past their best, but sufficient remained to afford an additional proof (if such were needed) as to their adaptability for garden decoration. The later plants were loaded with blossoms, and the names of the species and varieties that were in blossom may be acceptable to readers who take an interest in this genus.

It has been pointed out by an authority on Michaelmas Daisies that the "weakest point about them is their colour, or rather want of There may be some truth in this assertion if applied to the ordinary types generally seen in gardens, but it is scarcely applicable to the better forms as grown at Chiswick. Here we find a harmonious blending of colour, beautiful if not brilliant, and Various shades of sufficient to brighten a garden at this late period. purple predominate in the blooms it is true, but these only render more conspicuous the blue forms and those that have white flowers. Amongst others now in bloom at Chiswick are some very fine varieties of Aster novæ belgii, and these alone comprise a choice selection. A. n.-b. Robert Parker is a free-flowering form about 5 feet in height, but rather a straggling grower. Another good variety with deep rosy lilac blossoms is A. n.-b. Minerva. The well-known A. n-b. Harper Crewe is also seen to advantage at Chiswick, and this still remains one of the best white Michaelmas Daisies in cultivation. A form named Pluto, belonging it would appear to A. lævis, but labelled as a variety of A. novæ-belgii, is exceptionally fine, growing from 3 to 4 feet in height, and covered with large light coloured flowers. For making a display late in the autumn

A. lævis floribundus is well adapted, the flowers being of dark rosy purple shade, and the plant compact in growth. A. n.-b. Archer Hind is apparently a valuable late-flowering variety, attaining a height of 4 feet, with rosy lilac flowers; and the same may be said of A. n.-b. Leda, which has rather small dark coloured flowers. A. n.-b. Juno (given as a variety of A. lævis in the list mentioned) is one of the brightest varieties now in flower in the collection, the flowers being moderately large and of a rich purplish blue shade. An unnamed seedling from A. novæ-belgii x A. lævis was also noticeable, this being dwarf in habit, with a profusion of white medium-sized flowers. Another dwarf variety worthy of extensive cultivation is A. n.-b. densus, which is very compact in growth and the flowers lilac purple. Other good forms of A. novæ-belgii in flower last week included Albion, Fortuna, and Calliope. That confusion in the nomenclature of these plants still exists is indicated by the fact that whilst several kinds at Chiswick are labelled distinctly as varieties of A. novæ-belgii they are given in the Journal referred to as forms of A. lævis. This probably is because a large number of the perennial Asters grown in gardens are hybrids between A. lævis and A. novæbelgii; but notwithstanding it would prevent further confusion if the varieties were labelled correspondingly with the list to which allusion has been made.

Late-flowering varieties of A. novæ-angliæ do not appear to be quite so plentiful as those of the species above mentioned. The type is an attractive plant when well grown, being nearly 5 feet in height, and as a rule laden with fine rose-coloured flowers in October. Beautiful as the species is, however, the form known as A. n.-a. rubra is even better. At Chiswick this is about 3 or 4 feet in height, and bears an abundance of bright rosy red flowers. A. n.-a. pulchella is another very fine variety, rather dwarf in growth, with large deep violet flowers. Like A. n.-a. rubra this is very distinct, and should be given a place in every garden. Although rather straggling in growth and bearing medium-sized rose-coloured flowers, A. n.-a. roseus forms a pleasing feature when grown in a mass. A. n.-a. præcox is another desirable variety, which attains a height of 3 feet or so, and yields a profusion of light purplish flowers. The wellknown A. acris is a remarkably showy plant when seen at its best; but A. acris nanus is a decided improvement on the type from a decorative point of view. The plant is more dwarf and compact in growth, and the beautiful star-like purplish flowers harmonise splendidly with the graceful foliage. It is a grand variety for growing on rockeries. Those who favour the small flowered forms, many of which are exquisitely graceful if not particularly showy, will find A. cordifolius Diana worthy of at ention. This had white blooms and finely cut leaves. A. cordifolius elegans, as its name implies, is another good form, and the same may be said of a variety labelled A. cordifolius albula. The varieties of A. Drummondi have their good qualities, especially A. D. cora, which is rather tall in growth, and a fine late-flowering plant. A. versicolor Antigone (syn. discolor major) is a charming form, as also is A. v. Themis (syn. discolor), the latter being about 2 feet high, and of a compact habit. A. paniculata (syn. carnea) W. G. Grant, too, is deserving of more than a passing notice, and the same applies to A. lævis Virgil, which is a very fine form. Among the dwarf - growing kinds A. Amellus stands pre-eminent, but it is not so good as A. Amellus majus, which is, according to the plants grown at Chiswick, later flowering than the popular A. a. bessarabicus. It has large rich violet purple flowers. There are many more species and varieties grown in the collection referred to, but as before said, they were for the most part past their best at the time of my visit, hence a reference to the late-blooming kinds must suffice for the present. These are exceptionally valuable for the embellishment of gardens during October

Relative to the culture of the Michaelmas Daisies, that cannot be said to be a very difficult matter. With few exceptions they will flourish in any ordinary garden soil provided it is of a fertile character, but they repay any extra attention that may be given them by producing flowers more abundantly. This should not be overlooked by those who grow the perennial Asters, and a top-dressing of decayed manure in the spring is by no means a waste of labour. In some cases annual division when commencing growth in the spring is desirable, this treatment suiting many varieties of A. novæbelgii and A. lævis. The dwarf forms, such as the beautiful A. Stracheyi, alpinus, Amellus majus, and others might advantageously be employed for bedding, inasmuch as apart from their freedom in flowering many of them possess a graceful growth which well merits attention.—C.

NERINE ELEGANS ALBA.

This charming Nerine was exhibited by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, at the last meeting of the Royal Horticultural Society, and a first-class certificate was awarded for it. The plant shown was a small one, and bore one spike, about 6 nches high, carrying nearly

a dozen pure white flowers, as shown in the illustration (fig. 51). The exhibitor informed us that Nerine elegans alba "is a native of South Africa, probably Natal. It is not a garden form, but a wild species, and has been in his possession for two years only. It is almost hardy in this country, but he would recommend the protection of a cold frame during the winter in order to protect the leaves from injury, which would spoil the plant for a whole year. Of course, it requires its proper season of rest." Although less showy than the scarlet-flowered types, a white Nerine is somewhat of a novelty, and usually arrests attention.

FEEDING TREES AND PLANTS AND ENRICHING THE SOIL IN THE AUTUMN.

It has frequently occurred to me when advocating the adoption of definite cultural practices, that were we always to do it with the full force of our conviction we might unconsciously lead

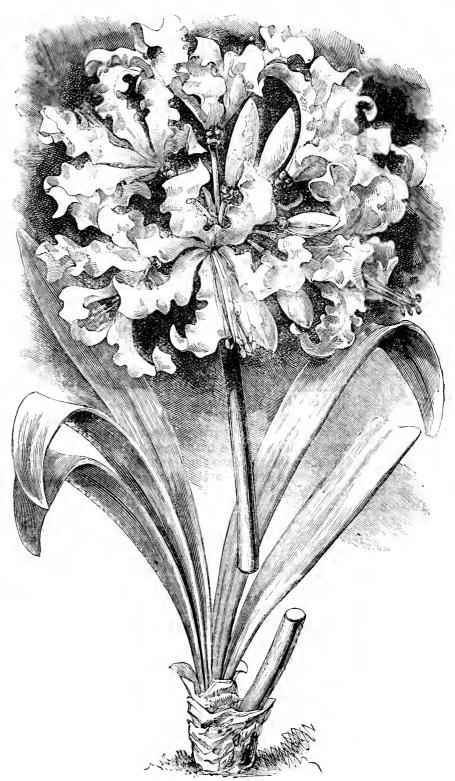

FIG. 51.—NERINE ELEGANS ALBA.

others to believe that the very existence of the plant or crop under notice depended upon carrying out to the letter the precise method of culture advanced, whereas we know well that equally good results may sometimes be obtained by pursuing a course which differs considerably in its cultural details. In the majority of instances, however, there are local circumstances, or the attainment a different object attempted, which fully account for the ultimate success of practices apparently at variance with each other. If these considerations are steadfastly borne in mind by gardeners of all grades many valuable lessons will be adduced which will help them to determine the best course to pursue at times when cultural problems present themselves, and which must

be overcome before cultivation of the highest order can be achieved.

Intimately connected with this subject of high culture is that of feeding plants and crops, indeed it is the very foundation of it, but the essential conditions to ensure success are that whatever fertilisers be given must be applied at the right time and in the proper way. Much injury may be done hy over-feeding or hy giving stimulants at the wrong time, and I have repeatedly pointed out in the Journal of Horticulture the disastrous effects of applying liquid manure in too strong a condition, or before root action is sufficiently advanced to require it. The whole question hinges upon the exercise of sound judgment in determining when this stage is reached, and the knowledge requisite for the purpose can only be gained by observation and experience. Let this point once be mastered and there is no comparison between the results achieved hy those cultivators who feed their plants and crops continuously and those of others who follow only haphazard or irregular methods of doing it. The former keeps innumerable diseases and insects at hay, which are a continual source of trouble to the latter, for it is an undoubted fact that vegetation of all descriptions speedily become a prey to their attacks when weakened through want of nourishment, or get out of health from other causes, while, on the other hand, when health and vigour are maintained insect pests are generally conspicuous by their absence.

The foregoing will show I hold the opinion that many of the ills from which plants suffer are hrought about directly or indirectly through lack of a sufficient supply of nourishment; hut let it he distinctly understood I add the saving clause, that this nourishment must be given under the right conditions if the hest results are to be obtained. In the spring and early summer our thoughts naturally turn to the practice of enriching the soil with manure, or feeding crops hy means of natural liquid manure or chemical fertilisers. This has become so much a matter of routine that in many instances feeding is carried on with a lavish hand during the period above named, and singularly neglected or only indulged in

spasmodically during the greater part of the year.

The question arises in my mind, Do we pay sufficient attention to feeding (especially in the case of fruit trees and plants in pots) during the late summer and autumn? I think not. The roots of the former are known to be extremely active during that period, and trees which have borne heavy crops of fruit derive immense benefit if liheral applications of liquid manure are given, either before or after the leaves have fallen, preferably before, as the buds are then enabled to develop to their fullest extent; the leaves heing kept healthy and robust continue to perform their functions till the gradually lowering temperature diminishes the flow of sap and causes them to turn yellow and drop very slowly, hanging with great tenacity to the branches till the last vestige of green has left them. The buds are thus nourished to their fullest development, and the trees begin the rest of winter in a sound healthy condition. With hard prominent buds and a natural fall of foliage the prospect for the succeeding year is always good. Contrast the condition of such trees with that of others which may have heen equally healthy during the previous summer, but having borne heavy crops of fruits were, hy the beginning of the autumn, in a partially exhausted state, and no special means being taken to enable them to recoup their energies, the leaves fall early and quickly, while the huds are neither so hard nor prominent as they should be. Trees which go to rest in this enfeebled state can scarcely he expected to produce vigorous flowers in spring, neither do they. Blossom there may be in abundance, but it either fails to set properly, or the greater part of the fruit drops in its early stages. Thus the loss of a crop of fruit may be distinctly traced to the neglect of feeding at a critical time. I am convinced there are thousands of fruit trees which would give infinitely better results if this matter received greater attention, though, unfortunately, in many instances, through pressure of other work, it is impossible for gardeners to give it, except in the case of choicer fruits, such as Peaches, Nectarines, and Pears on walls. Numbers of other fruit trees of various descriptions which have gradually drifted into a sterile state through neglect and continual starvation may often he met with. It is surprising how greatly old trees in this condition may be improved provided the branches are sound and free from canker, but too much must not he expected in one season.

In the case of old wall trees which have covered their allotted space, a regular thinning of both spurs and branches and the laying in of young shoots, if carried out in conjunction with judicious feeding at the roots, will in the course of a few seasons convert them into vigorous fruitful trees. No better time than the present could be found to give them the attention they need at the roots. The surface soil should be removed, starting at a distance of from 4 to 6 feet from the main stem, and gradually working to it. Occasionally roots will he found near the surface, but generally they are fully a foot beneath it, except near the main stem. Strong roots destitute of fibre may be frequently noticed striking deeply into the soil, or extending a great distance from the Trees in the condition above indicated derive their principal support from these; it is therefore unwise to disturb many of them until new roots have been formed nearer the stem; some, however, should, if possible, he traced to a point where they hranch into numerous smaller ones, there be cut asunder, trimmed at the points with a sharp knife, and afterwards notched at intervals of a foot throughout their entire length. A compost consisting of good loam six parts, fresh horse droppings one, wood ashes half a part, with a little soot, and should the loam he heavy lime rubble added, is an excellent one with which to replace the worn out soil removed. First place a layer of this underneath the hared roots, so as to bring them to within 6 inches of the ground line. Next draw the points of the long roots which have been severed and notched toward the main stem so as to confine them if possible to within a radius of 5 feet, secure them in position by means of strong wooden pegs, then cover them with the prepared compost, which should he trodden moderately firm. The surface when finished ought to be slightly above the ground level to allow for sinking. Over this a layer of short manure should be placed. In order to keep the roots of younger trees within bounds, a trench should be dug out every three years, at ahout 4 feet from the stem, the points of the roots cut with a sharp knife, and the trench filled in with the compost above described, a few inches of the surface soil between the trench and the stem heing also removed and replaced with fresh soil, always finishing off with a layer of short manure, unless the trees have a tendency to grow too strongly.

A certain position of this work should be carried out periodically, otherwise it will assuredly get in arrears. In all instances in which trees must perforce stand over for another season before they receive this necessary attention, much help may be rendered them by applying liquid manure during the autumn and winter months. Every drop of this valuable fertiliser obtainable may be turned to good account in this way, by storing in the soil the food, which the roots of trees and crops will not be slow to appropriate during their season of need.—H. Dunkin.

(To be continued.)

ARE TOMATO DISEASES CONTROLLABLE?

BACTERIAL AND EELWORM TROUBLES — SPECIMENS

"Hygienist" (page 325) may be congratulated on his endeavour to reconcile theory with practice-scientists with cultivators. This cannot too soon be effected, for there is really no difference between sound theory and successful practice. The one is of no value without the other, and I have come to regard them as synonymous for all

useful cultural purposes.

As regards hacteria it may safely be concluded that these bodies generate heat, inasmuch as they act on the principles of a ferment, and are most active under droughty conditions of the atmosphere or surrounding medium and in high temperatures. In this way only can we account for the deposits of nitrate of soda in Chili and nitrate of potash in India. It is also well known that the micro-organisms which render soils fertile are active in the summer when the soil is driest and warmest, and are passive in the winter when the soil is wettest and coldest. But we must bear in mind that hacteria, like other forms of life, may-nay, must-be separated into the useful and malignant, and it is important that the one be known from the other, else the first cannot be encouraged and the latter discouraged. When a soil is excessively manured year after year or cropped with the same plant in consecutive years, we know that something will sooner or later befall the crop. It may be that the ground of a kitchen garden becomes sodden and sour, but we rarely consider that we have encouraged the micro-organisms whose office is to convert matter into elements poisonous to the crops we desire to grow. Now, instead of pursuing this disastrous course, manure is withheld and we give a dressing of lime. What happens? The chemist will tell us that it effects certain changes, liberates ammonia, and does many other things. He will only tell us what he knows. There is no theory about; it has all been found out by scientific inquiry and hardheaded practice. I know what the result is from a cultivator's point of view; but I also want to know how, therefore must acquire chemical knowledge, and when I can ascertain whether the chemist's theory is correct and my practice sound. Many cultivators acquire this intuitively or glean it by a round-about system of empirical practice and repeated experiments, which are characterised by more losses than gains, and the outcome is that as little is known of the why and how at the close as at the commencement.

The chemist can only tell us so much and no more. ammonia liberated by the lime is not a particle of use as food for the crop until it is converted by one organism into nitrite, and hy another into nitrate. Therefore by the action of the lime we set machinery

at work, which converts the ammonia into nitrate of lime and potash, and the result is that instead of the crop, say Potatoes, being all top, there are abundance of tubers. The fact is we have checked or destroyed the malignant organisms, and brought into activity the useful. That is the way to come at facts, and it is only by so doing that we are able to give a satisfactory account of our practice.

Bacterium Halstedi is a malignant micro-organism. Its business is to live and perpetuate its species. It requires plants—Tomatoes, Cucumbers, Melons, Vegetable Marrows, and perhaps Potatoes to live upon, and in no instance has it been found upon native plants. This by no means points to the necessity of its being introduced, for it may after all prove to be a native of this country, just the same as Oïdium Tuckeri has been proved to be our very common Erisyphe communis, and the Potato fungus traced to Solanum Dulcamara. The worst part of the matter is that Bacterium Halstedi thrives under the same conditions as the useful bacteria do potentially in behoof of the cultivator; but in the present state of our knowledge of these micro-organisms it is hardly possible to arrive at any satisfactory deduction, nevertheless the malignant forms are certainly as foodrequiring as the useful, and it may safely be conceded that they are incapable of manufacturing that upon which they subsist, for all life is dependant upon that of another, or all life is parasitic, each and all doing its best to maintain place in the "struggle for existence."
"Hygienist" attributes fungal diseases to wet and bacterial

attacks to drought, and from a hygienic standpoint considers all to be due to some predisposing causes. Hygienists are all very well upon general grounds, but when anything special or particular occurs no one thinks of appealing to them, but wisely seeks aid from duly qualified specialists, and we may take it for granted that every cultivator of Tomatoes knows what suits his cultures. If we raise a number of plants from seed there is a difference in the individuals, both as regards health and fruitfulness, yet all are treated precisely What is the predisposing cause? Why is one strong and the other weak? Predisposing cause for sooth! heterodoxy, any and everything intangible, immaterial, may or may not exist, always subject of argument! But Bacterium Halstedi can be seen, examined, made sure of. It cannot be overlooked, it is past the region of hypothesis or metaphysical subtlety, is a substantial fact, which all may comprehend. If water will render it latent, for it can hardly kill a parasite living in liquid, all the better.

What I, however, particularly desire at the present time is a few inches of the stem and a similar portion of the root part attached of a Tomato plant infested with eelworm. If it has growth springing from the collar all the better, and to satisfy my requirements the part sent must be alive, for I want to ascertain if the nostrum I wish to subject it to is as safe to use as it is sure to kill the eelworm. If the result is satisfactory, anyone may make sure of the recipe by expending 3½d. in the Journal of Horticulture in which it may appear.—G. ABBEY.

[Any specimens that may arrive at this office for Mr. Abbey will

be forwarded to him.]

In reply to "Hygienist" on page 325, I should not like to say hastily that the Tomato disease is absolutely controllable, but I am convinced it is favoured by too close planting, and too much moisture both at the roots and in the atmosphere. As preventives, experience leads me to recommend-

1, Never plant closer than 2 fect between the rows, and 15 to

18 inches in them.

2, If disease appears pull out the plant first attacked at once.

3, Let a current of air pass right through the house, which will bring firm and short-jointed wood, so essential to good Tomato growing.—J. G. Pellinger, Harrogate.

A LARGE HOLLY TREE.

MAY I venture through your columns to describe a Holly tree which may be the largest in Great Britain, situated within ten paces of my house, which is $10\bar{40}$ feet above the sea?

I have in my possession a report which was made on it in January 1836, and at that time the tree "measured in circumference above the roots thereof 27 feet 6 inches, and estimated to be 60 feet in height, and

is very branchy, and the general opinion is that it is 400 years old."

The circumference of the tree now is 30 feet, and its height 43 feet, and has sixteen main branches, two measuring in circumference 11 feet 7 inches, and 8 feet 2 inches. It covers a circle, the diameter of which is 54 feet, and its branches have numerous initials and dates cut on them, those which can be still deciphered ranging from 1700 to 1864. The most legible is that of J. Broughton, 22nd August, 1756, which is almost as clear as the day on which it was cut. Many of the branches are half eaten through with rot, and I have had all the sixteen supported by iron rods. The tree still shows great vitality, each year bringing forth numerous young shoots. It is rather curious that on the opposite side of the valley is another large Holly tree, which measures 17 feet 6 inches in circumference.—Geo. W. LLOYD-VERNEY, Colonel, Clochfaen, Ulanidlage N. Wales Llanidloes, N. Wales.

LÆLIA GRANDIS TENEBROSA.

THIS is quite distinct from the type, and greatly superior to A plant I have in bloom now has flowers 6 inches across. The sepals and petals are wavy chestnut red, the lip is rose colour, elegantly fringed, and with darker lines leading to a blotch of dark rich purple in the throat, a really superb variety.

CATTLEYA BICOLOR.

Although this species is not so showy as some others, vet its distinct appearance should ensure it a place in every collection. The side lobes of the lip, which in most Cattleyas enfold the column, are entirely absent in C. bicolor, leaving the column exposed. The sepals and petals are brown; the lip is crimson, in some types with a distinct white margin, in others the colour gets fainter towards the edge. The flowers are produced on upright peduncles, which bear from five to twelve blooms each. It is a Brazilian Orchid, and grows and flowers freely with ordinary care.— H. R. R.

ORCHIDS AT CLIFFE HOUSE, HESSLE.

WHILST paying a hurried visit to Hessle last week I was invited to see the collection of Orchids in which B. Whitaker, Esq., of Cliffe House, is so deeply interested. I found some exceedingly fine plants of the better species present. Mr. Jarvis first took me to where two fine specimens of Cattleya Dowiana aurea and Cattleya chrysotoxa were in full bloom. The blooms were in excellent condition, very fine and well constituted. Some good flowers of Lælia purpurata were in the same house. A spike of Oncidium crispum had sixty-four flower buds on it, looking remarkably fresh. Several other good plants were in bloom. The Cypripediums, I thought, were especially healthy, and included Curtisi, Morgania, grande, Alice, callosum and Chamberlainianum.—W. CLAYTON.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 10TH.

SCIENTIFIC COMMITTEE.—Present: Mr. McLachlan (in the chair), Prof. Church, Dr. Müller, Mr. Blandford, Rev. W. Wilks, Dr. Bonavia,

and Rev. G. Henslow, Hon. Sec.

Peach Disease.—With reference to the diseased Peaches brought to the last meeting by Dr. Müller, Mr. G. Massee of Kew reports as follows:—"The Peach disease is caused by the fungus Glocosporium fructigerum, Berk., or rather by G. lacticolor, Berk., which is in reality only the former species modified by the host, as proved by cultures. In America, where the disease is too well known, and has also attacked Grapes during the last two or three years, it has been found that the fungus can be kept well under control by two or three sprayings of potassic sulphide (½ oz. to a gallon of water) applied in June or July. Of course, it is too late to attempt spraying this year, but all diseased fruit should be removed and destroyed to prevent the diffusion of the spores." Dr. Müller observed that he had seen the disease twice soon after the setting of the fruit. This appeared to be locally arrested in growth where the fungus occurred, the rest of the Peach growing normally.

Pyrus japonica Fruiting.-Mr. Blandford exhibited specimens, and commented on the very large size to which the fruit had attained this year. They do not appear to be capable of being put to any use

as yet.

Oranges from Australia.—Dr. Bonavia communicated the following remarks on a curious phenomenon connected with Oranges:—
"On the 12th July, 1893, a box of Oranges was shipped to me by a friend in South Australia. It contained four varieties of the so-called 'Portugal' Orange, viz., the 'Navel' Orange, a large and a small Blood Orange, and the Egg Orange. Each Orange was wrapped in tissue paper, and the whole were packed tightly in hay. They reached me after having been about five weeks on the sea in very sound condition, with the exception of one which was spoilt. Probably this had been bruised before it was packed.

"On the voyage the Oranges sweated and the hay became damp, for when I opened the box a musty smell of damp hay pervaded the whole

box; and now comes an interesting point.
"I unpacked all the Oranges and freed them from paper and hay. They all had a musty smell. I washed some of them and dried them. Apparently the musty smell was completely removed from the outside; but on cutting open the Oranges every one of them had not only a musty smell in the juice carpels, but also a peculiar musty flavour.

"It would appear that the mustiness of the damp hay penetrated through the peel and pervaded the whole interior of the Orange, giving

a peculiar and unpleasant flavour to the juice.

"There was no difference in the four varieties. They were all equally contaminated by the musty smell and flavour, although otherwise quite sound, and when washed the mustiness could not be detected

in the rind.

"I ate some of them every day, and by keeping the mustiness of the juice became less, till about the fourth week after unpacking the

mustiness in the juice was scarcely perceptible.

"All the varieties were rather thick-skinned and were very juicy, and all kept very well. Probably the soft hay packing may have had something to do with their not getting bruised on the way. The 'Navel' Oranges were more juicy than the same variety we get in London from California.

"I hardly know how to explain the contamination of the juice by the musty air in the box. The peel contains a large quantity of essential oil. This may have absorbed the musty aroma, and then, when saturated, passed it on to the juice vesicles which also contain a considerable proportion of essential oil. By keeping and exposure to the air, this process may have been reversed."

With regard to the cause of the flavour of the Oranges Prof. Church explained it by the fermentation of the hay and osmose causing the scent to enter; then transpiration would subsequently bring about the odour externally. It was remarked by Mr. McLachlan that certain Oranges were eaten green in Java and Ceylon. Dr. Bonavia added that such became yellow subsequently, though they were edible in the green state. They have been illustrated by Miss North among her paintings at Kew.

Pears Diseased. - Messrs. J. Cheal & Sons forwarded samples of Pitmaston Duchess Pears affected apparently by a fungus, giving the

fruit a warty appearance. They were referred to Kew for examination.

Salisburia Diseased.—A branch of this tree was received from South
Dorset, evidently in a very enfeebled condition. It was the general
opinion that the mild, damp, maritime climate of the situation was
unfavourable to it, and the probable cause of its unhealthiness.

Wasps and Pears.—Mr. Blandford observed on the habit of tomtits,
which he had seen pearing helps in Pears, which gave wasps access to

which he had seen pecking holes in Pears, which gave wasps access to attack the juicy tissues. Application of nicotine to the wound kept them at bay for six hours. Mr. Henslow added that he had noticed wasps attacking mealy bugs in a vinery before the Grapes were ripe. Mr. McLachlan added that he had noticed tomtits attacking Cob Nuts

for the purpose of extracting the grubs within them.

Cypripedium, Synanthy.— Sir Trevor Lawrence exhibited a plant having two flowers welded into one. It possessed one lower smaller sepal, two large ones above, three nearly equal sized petals, two perfect labella, and two staminodia; the ovary showed the fusion by a longi-

tudinal groove.

Rhododendron Hybrid.—Mr. Henslow exhibited a specimen received from Mr. Veitch, the result of crossing "Lord Wolseley" by the bigener "Indico javanicum," this having been the result of crossing "Lord Wolseley" with Azalea indica Stella. The flowers were more or less malformed, having a strong tendency to be polypetalous; the stamens were occasionally epipetalous or sub-petaloid. The form of the flower showed no improvement on that of Indico javanicum, though it was a little brighter in colour (crange) was a little brighter in colour (orange).

Oak Galls.—Some curious many-pointed galls on the acorns of Oaks at Versailles were sent by Mr. Belt of Ealing. Mr. McLachlan reports that they are the product of Cynips Calycis, and that this species of

gall has never been found in this country.

Matricaria Chamomilla Rayless.—Mr. Henslow exhibited specimens found by road sides in Ealing. They appeared to be particularly abundant last year. Seed obtained failed to germinate in the present dry season.

THE BATTERSEA PARK CHRYSANTHEMUMS.

WE are informed that upwards of 4000 persons passed through the Chrysantbemum house in Battersea Park on Saturday, Sunday, and Monday last, the number of visitors on Sunday being 3080. The plants are in admirable condition, and the display is increasing in beauty every day.

CHRYSANTHEMUMS AT WATERLOW PARK.

THE large conservatory and vineries at this park were opened to the public for two months on Saturday the 14th inst., from ten till four cach day, for the Chrysantbemum Show. There are over 2000 plants coming in flower, and these will make a better display than last year. There is also a collection of other flowering plants.

CRYSTAL PALACE SHOW.

THE Chrysanthemum Exhibition at the Crystal Palace this year will take place on November 3rd and 4th. Cut blooms, as usual, will form a feature, the principal class being for "forty-eight blooms, twenty-four Japanese and twenty-four incurved, in not less than eighteen varieties of each or more than two of one variety." The prizes offered are good, those in the class mentioned being £10, £7, £5, and £3, which should bring forth a keen competition. Mr. W. G. Head, Superintendent, Garden Department, Crystal Palace, S.E., will supply schedules and entry forms. WEST OF ENGLAND CHRYSANTHEMUM SOCIETY.

As announced in our advertisement columns the annual Exhibition of this Society will be held in the Guildhall, Plymouth, on November 14th and 15th. A comprehensive schedule has been prepared and liberal prizes are offered. The leading class is for forty-eight blooms, to consist of twenty-four Japanese and a similar number of Incurved in not less than eighteen varieties of each, the five prizes being £15, £10, £5, £2 and £1 respectively. Messrs. Wilson and Damerell, 4, North Hill, Plymouth, are the Honorary Secretaries.

CHARLES DAVIS.

LOVERS of Chrysanthemums generally, and especially cultivators of cut blooms for exhibition, are no doubt anxiously looking forward for the first appearance or report of this novelty. To many it is known that it is a yellow sport from that deservedly popular Japanese Chrysanthemum Viviand Morel.

I lately saw the variety under notice in bloom in the nursery of Mr. J. Agate, Havant, and have no hesitation in saying that it quite comes up to expectation. Like all sports it retains the habit of its parent, and splendid flowers are produced on plants 3 feet high. The first buds produce blooms pale primrose in colour decidedly pleasing. The blooms from the second buds are deep yellow in the centre, fading with age to a lighter tint towards the extremity of the petals, having here and there a tinge of colour. The later blooms develop as the published description gives them—canary yellow, beautifully tinted rosy bronze. upon Mr. Agate's plants measured 8 inches in diameter, and gave promise of proportionate depth.—E. MOLYNEUX.

NATIONAL CHRYSANTHEMUM SOCIETY.

WE are requested by the Honorary Secretary to state that on the occasion of the great Exhibition at the Royal Aquarium on Nov. 7th, 8th, and 9th, the flowers competing in class 27 of the amateurs' division will be considered when the special medals are awarded. This class was unfortunately omitted from those mentioned on page 64 of the schedule Also that the awards in class 48, being special prizes offered of prizes. by Mr. E. C. Jukes, will be the silver-gilt, silver, and bronze medals of the Society. The Floral Committee will meet on the second day of the Show, Wednesday, November 8th, at two o'clock, and not on the first day as heretofore.

CERTIFICATED CHRYSANTHEMUMS.

THE following new Chrysantbemums were awarded first-class certificates at the Floral Committee meeting at the Aquarium on the

Charles Davis (Mr. H. J. Jones).—A deep bronzy yellow sport from the well-known Japanese variety Viviand Morel.

Eda Prass (Mr. Godfrey).—An American seedling of the Japanese type; colour, soft salmon rose. Madame Edouard Rey (Mr. E. Beckett).—A large Jaranese incurved

flower, light purple amaranth, with rosy reverse.

Louise (Mr. N. Davis).—A fine large white Japanese incurved variety, with deeply grooved florets, tinted blush.

Malle. Thérèse Rey (Mr. H. Shoesmith).—A large Japanese, with long drooping florets. This and the two preceding were raised by Mr. Ernest Calvat.

Edith Rowbottom (Mr. E. Rowbottom).—A Japanese bloom, colour lilac amaranth, petals rather narrow; a seedling raised by the exhibitor.

Among other interesting flowers, of which more may be heard later on, were L'Ami Etienne, Vice-President Jules Barigny, Lizzie Seward, Violetta, Mrs. P. Blair, and G. W. Childs.

CHRYSANTHEMUMS AROUND LIVERPOOL.

ONCE more the season is at hand when notes relating to Chrysanthemums are of special interest. On all sides the opinion expressed is that the early blooms will be somewhat coarse, yet, notwithstanding, a very fine display is anticipated. To Liverpool people the great event of the forthcoming Show is the prize given by Messrs. R. P. Ker & Sons for twelve incurved, twelve Japanese, and twelve reflexed blooms. The prize consists of a magnificent challenge wase, value 20 guineas, with 10 guineas in each wash was until finally man to be a second was a s with 10 guineas in cash each year until finally won, to be won twice consecutively or three times in all, open to growers within twelve miles consecutively or three times in all, open to growers within twelve miles radius of the Liverpool Exchange. In 1891 it was won by the late Mr. A. R. Cox, and last year by Mr. Jellicoe, gardener to F. H. Gossage, Esq., who will do his utmost to secure the trophy this year. Another event is at the neighbouring Grassendale Show, where Mr. Donald Forbes, gardener to Alfred Holt, Esq., Crofton, Aigburth, the winner of the 10 guinea cup presented by A. L. Jones, Esq., and also last year's winner of the 10 guinea prize at Liverpool, means to make a bold bid for the retention of the cup as his own property. As in former years I for the retention of the cup as his own property. As in former years I can only note the more important of the growers, at the same time bearing in mind the fact that good work is being done by smaller growers, although not figuring on the exhibition boards. The remainder of my notes will be completed next week.

LINGDALE LODGE, OXTON, CHESHIRE.

A GENUINE lover of the Chrysanthemum was the late Mr. George Cockburn, who has passed away since my notes of last season, but it is gratifying to find that their cultivation is being continued by the family, who all share the same interest. Mr. George Burden, now well known, has this season 400 plants, his Japanese varieties being very good. The most noticeable are W. H. Lincoln, Puritan, Stanstead White, Mrs. F. Jameson, Etoile de Lyon, Viviand Morel, Mdlle. Marie Hoste, Mons. Bernard, Mrs. Wheeler, Edwin Molyneux, G. C. Scwabe, Sunflower, Mrs. Irving Clarke, W. Tricker, and Avalanche. Of newer kinds the most promising are Beauty of Exmouth, Lord Brooke, William Shrimpton, and Princess May. Amongst incurved the Queen family is represented by fine plants and stout foliage, but Mr. Burden is afraid that the buds are not so kind in opening as in other seasons, but he will have fine blooms nevertheless. Princess of Wales, Mrs. Heale, and their sports are fine, as are also Prince Alfred, Lord Wolseley, John Salter, Jeanne d'Arc, Refulgence, and Lady Harding. Of the newer kinds Mons. R. Bahuant is grand, but inclined to be early, whilst Madame Darrier is superb.

BOSCOBEL, NOCTORUM, CHESHIRE,

The residence of C. J. Proctor, Esq., the esteemed President of the Birkenhead Chrysanthemum Society, is well worthy of mention, by reason of the excellent blooms which Mr. J. Williams, Mr. Proctor's gardener, exhibited last season. They grow over 200 plants which are this season most promising. The best of the Japanese are W. H. Lincoln, Stanstead White, Mrs. F. Jameson, Etoile de Lyon, Viviand Morel, Mdlle. Marie Hoste, Mons. Bernard, Avalanche, Mrs. Wheeler, W. Tricker, Sunflower, G. C. Scwabe, and E. Molyneux. The incurved are very fine, and particular mention should be made of Princess of Wales types and those sometimes "miffy" ones, John Salter and Refulgence. Madame Darrier is excellent.

CROFTON, AIGBURTH.

Here Mr. Donald Fornes has some grand plants, fully equal to former years. The fine summer seems to have suited especially such kinds as E. Molyneux, Mrs. C. Wheeler, Beauty of Castlewood, G. C. Schwabe, W. Tricker, Mrs. F. Jameson, Viviand Morel, Gloire du Rocher, Colonel W. B. Smith, W. H. Lincoln, Avalanche, W. Lane, Aïda, Coronet, Mdlle. Marie Hoste, and Stanstead White. Of newer kinds, those which at present stand out prominently are Wm. Seward, Dorothy Shea, Mrs. C. Harman Payne, Mrs. E. D. Adams, L'Ami Etienne, Chas. Davis, Brookleigh Gem, Lucy Kendal, Henry Perkins, and Baron Hirsch. The Queen and Princess types are most promising. The open weather has been most favourable since the plants were housed, and should it continue the prospect is good for our early Show.

AIGBURTH HALL,

The residence of Mrs. Arthur Cooke, is a fresh addition to these notes, but as the gardens are presided over by Mr. Charles Osborne, who made his name famous when at Aymestrey Court, Woolton, all readers will be glad to hear something of his doings in his new charge. Though rather late on entering his duties here, he has a good collection of fine healthy plants, the best Japanese being Bouquet de Dame, Anna Hartzhorn, two varieties; Sunflower, E. Molyneux, W. Tricker, Puritan, Stanstead White, Boule d'Or, W. W. Coles, and Mrs. F. Jameson. These are excellent, and rightly timed. Newer varieties very good in bud are R. C. Kingston, Florence Davis, Col. Smith, and W. Lane. Of incurved, the Queen family on early buds are inclined to be rough. Plants stopped the first week in June are very promising. All the Princess family are just unfolding; these were stopped the second week in June. Mons. R. Bahuant is very fine, and Lord Wolseley and Madame Darrier, as elsewhere, are excellent. Viviand Morel on the early bud is exactly similar to Meg Merrilies without a tinge of pink in it.

About fifty plants in 6-inch pots for conservatory decoration are worth mentioning. The main plants were run on to four shoots after the break, and the second week in July one top shoot was taken from each plant, placed in thumb pots and put under handlights in the greenhouse. As soon as rooted they were transferred to 6-inch pots. Now they are from 3 to 22 inches high, with grand buds and every promise of proving a welcome change from all those grown on the

orthodox system.

CLEVELEY, ALLERTON.

Never on any previous occasion has Mr. Cromwell had such a promise of fine flowers, the 700 plants being perfect. The Princess family have fine shapely buds. Those of the Queen types, which are excellent, are Queen of England, Mrs. Robinson King, Lord Alcester, Empress of India and others. The Japanese are very good, and the following are now developing into substantial blooms, viz., Beauty of Castlewood, W. Tricker, Florence Davis, Mdlle. Marie Hoste, Sunflower, Viviand Morel, Stanstead White, Mrs. F. Jameson and others. Of the newer ones, Wm. Seward is very fine, and we must bid adieu to Jeanne Delaux to make way for the new comer, which hesides its colour, has such a robust constitution. G. W. Child, John Shrimpton and Colonel W. B. Smith are developing into fine flowers. Baron Hirsch is very promising as a new incurved, and one of the best of its colour.

To the above I may append a note which should not be overlooked by gardeners who grow Chrysanthemums for decoration as to the usefulness at the present time of the three varieties—Bouquet de Dame, Mons. Wm. Holmes and Gorgeous, white, red and yellow, which flowers in advance of the general collection. The corridor at Cleveley at the present time contains 120 plants of these varieties, each plant carrying three fully developed blooms, and I need hardly say that the effect is

grand.—R. P. R.

LESSONS OF THE DRY SEASON.

[Read by Mr. George Bunyard at the last meeting of the Horticultural Club.]

THE year 1893 will stand out in the memories of all connected with gardening and agriculture as an unprecedented one, the absence of rain for such long periods and the extreme heat having in some cases had disastrous effects alike on garden, arable field, and pasture. In

opening a discussion on this question one is struck by the many-sided phases of the subject, and it will be only possible to take up that embraced by the word Horticulture. Starting in February, we had a month of almost continued wet. The land was happily saturated, and lucky were those whose soil permitted them to get in the main garden crops early while the moisture was able to assist germination. In the vegetable garden the crops most affected were Peas, Broad Beans, Beet, Turnips, and Onions. Some of the seeds of these never germinated, and until the May rains came there seemed little chance of crop, but when the plants began to grow they made quick progress, and from the evidence of many vegetable shows most excellent examples were produced.

Never has there been a year in which the cultivators have so beaten the mere "growers," for where deep cultivation and frequent loosening of the surface soil by hoeing was carried out the crops did not suffer to the same extent as where the land was left alone; and on the farm it was the same, grand crops being secured where high-class farming was

carried out.

Naturally the vegetables liking warmth, or native to warmer climes, have done well, Tomatoes ripening thoroughly outside; Dwarf French Beans grew rapidly, but soon became too old for the kitchen; Runners grew, but the hlossom fell off wholesale, and there was one crop near the ground and another at the top. Marrows grew finely where they had any food to live on, but outdoor Cucumbers were nil. At one time it looked as if Winter Greens and Sprouts would be altogether lost, but they have pulled round. These results emphasise the fact that all the hard work of a kitchen garden should be done in the winter—i.e., trenching, manuring, and preparation of the seed beds. So far for vegetables.

In the fruit crops the summer has done wonders. Starting with Strawberries, where these were planted on decply trenched and enriched land they gave splendid results, and many second-rated kinds came to best quality, as Noble, Competitor, John Ruskin, and others. The Queen race did not do so well, the late ones were unable to hold out till Strawberries from Hampshire were in the London the crop set. markets on the 4th May, and extraordinary prices ruled for the early pickings. Paxtons made 10s. 6d. per gallon. The lesson we have in these useful fruits is evident where growers had left beds over two years old. They failed to get a crop worth the trouble of picking, and it was the same in gardens. I am more than ever convinced that two years is the full limit of a paying Strawberry crop. We have had several pounds of fruit in October from Vicomtesse Héricart de Thury. Gooseberry and Currant crops were in many cases quite dried up, and in July put on their September garb, but what fruit was saved was of fine flavour; and Raspberries were almost a failure. These again are left too long on the same land. If planted on well prepared ground and thoroughly surface dug they will last good for six years, but new beds are better then made, and the manure should be put on the surface.

As may be supposed, extra fine Peaches and Nectarines have been grown on open walls this year where care has been taken to water the trees freely and to keep them syringed. Apricots have borne the best crop for many years, and no doubt the well ripened wood in these stone fruits will remain a witness to the grand time they have had. Nectarines from their more tender skins were sadly spoiled and shrivelled by the scorching sun, and the lesson we may learn from this is that they will in such times pay for a partial shade, and more foliage should be left on them than we usually leave on Peaches. The flavour of both has been exceptionally fine, and the crop from two to four weeks earlier than usual where these fruits were grown in an orchard house. They have needed great care, and some shade was necessary to

reduce the excessive evaporation.

Pears were literally scorched off the trees by the heat and sun in April. The few remaining on some trees naturally came to an abnormal size, and the fruit shows have given us notable and record examples. On walls the crop has been good generally except where very hot, as We had a long line of cordons quite fruitless because we stated above. put them on a tarred fence and omitted to whiten it over. Many kinds which only come to perfection in such seasons as the past have been extra fine and clear in the skin, I allude to such as Glou Morçeau, Bergamotte Esperen, Easter Beurré, Madame Millet, Beurré Rance, Chaumontel, Duchesse d'Angoulême. Beurré d'Anjou, being grand in size and without a crack or spot. The palpahle lesson here is that we ought to place all such good, but "difficult-to-grow" sorts, on south or south-west walls, where they would in many cases do better than Peaches and Nectarines, especially in those old gardens where the nailholes in walls form a happy hunting ground for aphides, red spider, and that evil family. Many sorts have taken on grand co'our, and the open cordon Williams' Bon Chrêtien have been equal to the imported fruit in point of colour and clearness of skin. Never before have we seen such grand crops of this Pear on standards, in which form many others came large and fine in colour and quality. I anticipate the late and fine sorts, such as Beurré Rance, Doyenné d'Alençon, Duchesse de Bordeaux, and Olivier des Serres, will, beyond the above, be of fine quality, while healthy wood fully ripened will, in a great measure, prevent canker. Pears, usually ranked second-rate, has been grand; General Todtleben, Beurré Clairgeau, and Grosse Calebasse quite fine.

Apples, the great British crop, have been a grand exhibition. All kinds have developed not only size but splendid colour and clear skin. There is only one that has failed to reach its maximum—ie., Ecklinville. It may be that it misses the frequent showers of its native Emerald Isle. Calville Blanc, Reinette de Caux, and even Newtown Pippin have been quite good outside, and no kind has shown any spot or crack where cultivation has been carried out liberally. The so-called growers of fruit in neglected orchards have had a reverse, which it is

hoped will open their eyes to see that unless they thin out their trees and give them some root assistance by liquid manure or mulching, they can never get a profitable crop in face of the fine examples now put on our market from well-managed trees on cultivated land. More and more it is evident that if fruit culture in this land is to succeed we must bring into it all the gardener's thought, care, and attention. In passing, a word as to the marvellous colour in Apples this season. A preacher said recently, that after he had seen the vineyards of the south, and the flowers and fruits of that region, he should readily give the palm to an Apple orchard in its wreath of September coloured fruit. The Winter Queenings, Colonel Vaughan, and others were scarlet in colour. As an expert I have fruit sent from all parts for naming, and it has been a "lesson of the season" to see the same kinds from different people, in some cases four times as large as that from trees not properly cared for.

I am of opinion that we should grow some of our Apples on walls, the beauty of the fruit and the fulness of flavour then obtained seems to indicate they ought to have some such warm position. Calville Rouge, Sturmer Pippin, Washington, and other fruits, which have not always time to finish in our short summers, are very fine this year. Many kinds have been so large as to suggest a doubt as to their authenticity, Kerry Pippin, several Pearmains, Duchess of Oldenburg, being twice or three times their usual size; other Apples passing as kitchen sorts are sweet table fruit. I am inclined to think the far travelling and deep rooting nature of the Apple has been much in their favour. Canker in such sorts as Lord Suffield has been quite wanting, and the trees are wonderfully strengthened for future crops by an abundance of hard well ripened wood. It is remarkable that the surface rooting Paradise stock has given such fine fruit in a dry season, as even where mulched early there has not been rain enough to set free the stimulating properties of the material used.

I anticipate in lifting time we shall find they have made more tap roots than usual. Where land is full of porous and water-absorbing stones the drought has been little apparent, and it may be well to add this to our other lessons, and introduce stone of the nature of our Kentish surface ragstone where these do not exist on one of the most stony spots in our nurseries. The maiden Apples are grand and sturdy, and close to 6 feet tall. On flinty or gravelly lands they have suffered severely. Naturally, as a pomologist, I dwell much on this subject; but I trust not more than its importance deserves. It is quite evident we try to grow many sorts of fruits which our capricious climate does not as a general rule suit, and from the knowledge thus gained we may learn much. Where the land has been kept clean by constant moving of the surface soil no doubt a store of good has been laid up for many years to come, and as far as fruit is concerned I look upon the Indian summer

just passed as an untold blessing.

Passing now to the flower garden, what a trying time we have had! Herbaceous plants completely dried up, with us no flower on Pæonies or the tall growing Campanulas, Alpines gone never to return, Roses over in a "flash in the pan," and only here and there in the season a glimpse of what they might have been, until the autumn when they have, so to speak, made up for lost time, and given us a grand display. The Teas have naturally done best, and those who have cultivated deeply will have reaped a reward; but most will have, like myself, to find comfort in the fact that if the trees have made little wood that it is well ripened, and may resist a strong frost successfully. The worshippers (and they increase fast) of the Daffodils have been seriously curtailed in their devotions, for the flowers literally rushed out and then withered, several not even showing their beauty. Possibly they look to more highly developed bulbs for a grand display in 1894.

Bedding out was a serious matter, yet the display has been bright, because there has been an absence of coarse leafage, telling us to keep these beds a little less rich. Begonias with me have failed when they did show flower; a gale generally scattered the half-opened blossoms, and never have the beds been gay. They seem to like a partial shade; in this position I have seen good beds. Cactus Dahlias have been extra fine, and the Pompons very chaste. A dry time evidently suits these; it says we should start them early and grow into size, so as to make the most of our summer. I must not touch Lilies, Chrysanthemums,

and the like.

I now pass to Conifers and forest trees. The early leafage of these was grand, and seldom was it seen to such advantage. Many trees have, however, died outright from want of food, and here we may learn to persevere in Philip Frost's system of surface feeding for choice examples. Flowering shrubs have been very short-lived, and Lilacs were burnt up while half opened; on the other hand, the double kinds were grand. I would here put in a plea for all these striking shrubs, and ask if we treat them fairly by relegating flowering shrubs to crowded shrubberies and plantations. How seldom we see a fully developed example of any of them on our lawns, and when we do, how grand is their proportions, and what a glorious sight they are in flower! I refer to such as Guelder Roses, Lilacs, Syringas, and the Sumach. I have not alluded to the trying time for plants under glass demanding extra care on the gardener's part. It is, however, evident that the lesson here is—provide more shading that can be used at short notice, and remedy defects in the want of more ample ventilation.

The utmost care has had to be exercised in keeping down aphides, and all garden pests and wasps have never before been so numerous. Lay in a store of materials ready to begin battle should they appear in 1894. I have wandered in my subject, and have rather outlined a map, and will leave others to fill in the details and point out the omissions and defects of my paper.

EVENTS OF THE WEEK.—But few events of horticultural interest will take place in the metropolis during the ensuing week. The Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, Westminster, S.W., on Tuesday, the 24th inst., when, as mentioned elsewhere, a special display of vegetables and fruit is anticipated. A meeting of the Floral Committee of the National Chrysanthemum Society will take place at the Royal Aquarium, Westminster, on Wednesday, the 25th inst.

THE WEATHER IN LONDON.—As mentioned in another paragraph, the weather has been unusually mild in the metropolis during the past week. Much rain has also fallen at intervals. Sunday proved fine, as likewise did Monday, but it rained more or less all Tuesday. Wednesday opened fine and bright, similar weather continuing at the time of going to press.

ROYAL HORTICULTURAL SOCIETY.—The next meeting will be held on Tuesday, October 24th, in the Drill Hall, James Street, Victoria Street, Westminster. The Council of the Society have offered special prizes for Apples and Pears grown in the open air, and also for Grapes. At 3 P.M. Mr. A. Dean, F.R.H.S., will deliver a lecture on the cultivation of Onions, examples of which would be welcomed at the meeting.

DEATH OF MR. H. E. C. BEALE.—We regret to hear of the death, on the 12th inst., of Mr. Herbert Edward Child Beale, eldest son of Mr. E. J. Beale, of the firm of Messrs. J. Carter & Co., High Holborn. The deceased, who was a very amiable and promising young gentleman about thirty years of age, was educated at King's College, and then took a prominent position at Holborn, but his health broke down, and we understand he has spent most of the last two or three years in California, Jersey, and the south of France.

HORTICULTURAL LITERATURE.—A GOLD MEDAL AND 10,000 FRANCS (£400) PRIZE. At a meeting of the National Society of Horticulture of France on the 10th of August, 1893, the President called attention to the paper of M. Charles Baltet on the Comparative Study of French and of Foreign Horticulture. The subject was one of six which had been proposed for treatment at the Horticultural Congress in May, 1893, and for it M. Baltet had been awarded the gold medal which the National Society of Horticulture had placed at the disposal of the Congress. Also that in consideration of the same work the National Society of Horticulture had seen fit to award to M. Charles Baltet the prize of 10,000 francs bequeathed by the late Dr. Joubert de l'Hyberderie for the purpose of encouraging literature conducing to the advancement of horticulture. We are informed that this is the most distinguished honour of its kind hitherto conferred in France, and congratulate the distinguished pomologist on its acquisition.

- THE FRUITERERS' COMPANY. - A dinner was given on Wednesday evening the 11th inst., at the Mansion House, by the Lord Mayor and the Lady Mayoress, "to meet the court of the Fruiterers' Company." It was preceded by the presentation by the Company, in accordance with ancient annual custom, of a choice collection of English-grown fruit, the ceremony taking place in the drawing-room. After dinner the Dean of Rochester (chaplain to the Fruiterers' Company), in proposing the health of the Lord Mayor and Lady Mayoress, remarked that there were times when fruit had become a most important factor in the prosperity of the country. As regarded the owners, the occupiers, and the labourers on the soil, he regretted to say that there was most profound ignorance with respect to fruit, in connection with which he thought we had rather retrograded than progressed. Leaving out Herefordshire, Worcester, and Devon, the orchards of England were generally a disgrace, but there was really a grand future open for fruit. The farmer had been standing still, while the manufacturer had been making immense progress. Every landlord ought to try and get his tenant to make a profit from all sources on his farm. There were great possibilities in the advancement of the culture of fruit, and he was proud to belong to a society which had done much in this direction.

- —— DEATH OF-MR. W. Y. DRAPER.—We regret to hear of the death, on the 7th inst., at 14, Addison Crescent, Kensington, aged sixty, of Mr. William Yates Draper, the head of the firm of Messrs. J. W. Draper & Son, the well-known salesmen of Covent Garden. The funeral took place at Brompton Cemetery on the 11th inst.
- The concert in aid of the Library and Gardeners' Benevolent Institution which had been promoted by members of the above Society was held last Thursday, and was a great success artistically, and it is to be hoped financially. The gardeners decorated the room in a manner worthy of all praise. The chair was occupied by Holbrook Gaskell, Esq., J.P., Woolton Wood, who made a few appropriate remarks during the interval.
- A NEW SOLANACEOUS PLANT.—It is stated that M. de St. Quentin, in the course of a voyage of exploration in Uruguay, has discovered upon the banks of several rivers a Solanaccous plant giving edible tubers in abundance, analogous to those of the Potato. According to the Illustration Horticole, the Horticultural Society of Marseilles has decided to offer a gold medal to the importer who shall introduce this new plant into Europe in a living state. Another gold medal will be decreed to him who shall obtain the first return or produce of the new plant in question.
- RIPE STRAWBERRIES IN OCTOBER.—Mr. G. Freeman, Akeley Wood, Buckingham, writes—"In last week's issue (page 333) your correspondent Mr. Garner gives an instance of having gathered a dish of ripe Raspberries on the 4th inst. On going over my Strawberry plot on the 9th inst. I discovered several clusters of fruit, some of the berries showing colour; trusses of flowers are also noticeable. The Strawberries were produced by plants that have already fruited in the open, and not by those that have been forced and planted out. It would be interesting to learn if other gardeners have experienced similar results."
- MILD OCTOBER WEATHER.—A great rise of temperature was experienced over our islands on Friday last, and the following two days the air has been singularly mild and humid. On Saturday the shade temperature rose to between 60° and 65° in most parts of England, and in the course of that night scarcely any change took place, the minimum readings being in many cases as high as 58° and 59°. In London, where the thermometer did not sink below 58°, the night was, with one exception, the warmest experienced in the month of October for more than twenty years past. The only warmer night was in 1876, when the minimum on the 9th was as high as 61°. On Saturday last the maximum day and the minimum night temperature were identical—57° in Battersea Park, a circumstance that has not been previously observed by Mr. Coppin, the Superintendent.
- Ostrowskia Magnifica.—Apropos of the remarks of Mr. S. Arnott (page 282) regarding this plant the following, written by a correspondent in "Garden and Forest," may interest readers. "Herr Max Leichtlin states that this plant was flowered at Baden-Baden in 1877, where it is as hardy as a weed. It prefers a sandy, deeply worked soil, as it has thick brittle roots some 2 feet long. It was first discovered by Dr. A. Regel in Eastern Bokhara, and described in 1884. My plant has passed two winters safely, and has not appeared above ground until all dangers from spring frosts are over. It is four years old, now flowering for the first time. As it dies down to the roots soon after flowering it should have a position where it is not likely to be disturbed by careless digging, for though it is propagated by division of the roots it is not a plant which should be disturbed. My plant is in a position where it receives little moisture in late summer, but I do not know that this precaution is necessary."
- LARGE SOFT APPLES. Having one of the best private collections of Apples nearly all on bush trees, at Maiden Erleigh, the samples cannot be excelled anywhere on trees of similar growth, Mr. Turton is in a good position to judge of the keeping merits of the diverse sorts this season, and he told me the other day when looking through his fruit room that all the large samples were keeping badly, and would soon be over. Thus it would seem that having had one of the finest Apple seasons of the century (Pears included) we should have to pay the penalty of finding all our largest fruits to be very fugitive in quality. This bears out what I have learnt in other directions. One famous Pear grower told me that he had found very fine Pitmaston Duchess Pears to waste 5 ozs. weight in a fortnight. Practically these large fruits are some 60 per cent. of water. That is what so rapidly wastes. Solid fleshed Apples, especially the small firm section, will keep very well. So also will Pears, but generally we shall see all varieties spoiling earlier than usual.—A.

- WEGETABLES AT THE DRILL HALL.—Hardy fruit having had such a good innings at the late meeting of the Royal Horticultural Society, we are pleased to learn that on Tuesday next vegetables are expected to be seen in fine form. Amongst others Messrs. Sutton and Sons will, we learn, exhibit a very large collection of Onions and other roots, and other kinds of interest. Vegetables are seen too seldom at these meetings, but few exhibits create more interest, or are of greater usefulness.
- Belladonna Lily.—The bed of the above Lily mentioned in the description of Grimston Park, Tadeaster, a short time ago (vide Journal of Horticulture, July 20th) was, when I visited that place a little over a week since, in the height of its beauty. This bed is 35 yards long by 18 inches wide, faces the south, and is backed by the plant stoves and fernery. I counted 375 spikes, all in bloom, some with five, and one or two with six flowers on a spike. Only those who have seen such a sight can realise the grandeur of this flower, which, having no foliage as a background, has to rely entirely upon its own natural beauty to prove its claim to a place in gardens.—W. CLAYTON.
- Turton at these gardens the other day, I could but notice in walking round the truly wonderful crop of long handsome pods he had hanging upon very tall lines of Runner Beans in two diverse gardens. Asking if they were novelties, I was told that whilst one variety was Sutton's Selected Scarlet Runner, certainly a splendid selection, the other was Sutton's Prizewinner. Mr. Turton said, "We have had a wonderful crop, having been gathering by bushels, and of either it would be difficult to find a handsomer, cleaner sample." The Prizewinner had been sown at the usual time, middle of April, being employed to enclose an area usually occupied with hardwooded plants in the summer, and had gone up 12 feet in height. The others had been sown a month later, and of the two were then the heavier cropped. Still on October 14th there were very heavy crops hanging on the row sown just six months previously.—A.
- Covent Garden Supplies.—The exceptional summer we have been getting seems to have had hardly so great an influence on Covent Garden supplies as might have been expected. Through the drought supplies of green stuff fell off enormously so far as our own market gardens within a short distance of London were concerned. The Superintendent of Covent Garden tells us ("Daily News") it irequently happened that the supplies from the grounds around London were fifty waggon-loads short of what they would have been with a normal amount of rain. But the falling-off in Fulham and Kent was to a large extent compensated for by an inflow from the Fens and from Yorkshire. The recent rains have, of course, rapidly brought on crops nearer home. The effect of this was manifest in last Saturday's market, and prices will soon drop to a point at which it will no longer pay to send produce to London all the way from Yorkshire.
- VERY large consignments of APPLES have come to London from our own orchards this autumn, and foreign supplies have been quite out of it. In scarce years we get large consignments of Apples from Germany, Belgium, Holland, and Denmark, as well as France. French growers send us some very fine fruit, and we can always do with some of their Apples; but the other countries named grow chiefly very inferior fruit, and have no chance at all when our own orchards are fairly fruitful. We are getting some from France, but Worcestershire and Devonshire growers have of late years recognised the importance of growing only the finest kinds, and they are able to hold their own against all comers, and this year their consignments are very fine indeed. We obtain our late supplies from America ordinarily, and many Apples of very fine quality have been coming to us from Australia. Both have imported some of our best kinds, and have been successful in their cultivation, but English growers who have been careful and enterprising are now holding their own against all comers.
- THE wisdom of the BENGAL PEASANT CULTIVATORS finds expression in proverbs, of which a collection has been made by a Babu in the Agricultural Department of that province. His appreciation of the outwardly revered Brahmin betrays itself incidentally in the maxim, "Rain and inundation disappear when south winds blow, like the Brahman as soon as he has received his fee." Other Bengal rural aphorisms are: "Have the land which receives the washings of the village, and the bullock which walks fast, and marry the girl whose mother is good." "He who works in the field himself with the labourers gets the full profit; he who, being unable to work himself, supervises the workings of the labourers, gets half the profit; he who orders the labourers from his house does not get enough to eat."

GARDENING APPOINTMENTS.—Mr. J. Brooks, for over four years foreman in the gardens, Cringle House, Cheadle, Cheshire, has been appointed gardener to J. Johnson Houghton, Esq., Westwood, Neston, Chester. Mr. G. Stones, for the past two years with T. D. Grimke-Drayton, Esq., Golborne Park, Newton-le-Willows, as head gardener to R. Heywood Thompson, Esq., Nunwick Hall, Penrith, Cumberland.

— EXHIBITION AT LYONS.—We are informed that arrangements have been made to hold a universal, international, and colonial Exhibition at Lyons in 1894, and to include a section devoted to horticulture. There will be a permanent horticultural Exhibition open from April to October, divided into sections, including exhibits relating to all branches of horticulture, arboriculture, and market gardening, as well as various temporary shows, which are to be held every month, and to last for a week. Applications for space in the horticultural section should be directed to M. J. Claret, Palais Saint Pierre.

—— STRAY TOMATOES.—Many thousands of Tomato plants are growing on the extensive sewerage farm at Beaumont Lees belonging to the Leicester Corporation. They appear to attain the greatest vigour on the one-year-old sediment, which is pumped from the tanks into large beds surrounded with turf tanks, in which the sediment is about 2 feet in depth. There is no doubt these plants would have ripened very fair crops this season if they had been thinned in good time, as is proved by many isolated plants which have done so. Seeds of Apples, Pears, Oranges, Grapes, and a host of exotic Grasses and other plants, also germinate and flourish for the time being, especially in the neighbourhood of the tanks, with great vigour. Many fields of Rye Grass have yielded four full crops this season on this sewerage farm.— J. H. W.

- HYBRIDISATION AND CROSS-FERTILISATION.—This was the subject of a lecture given by Mr. C. E. Pearson of Chilwell Nurseries, Nottingham, at a meeting of the Wakefield Paxton Society on the 7th inst. Mr. Pearson spoke for about an hour, and his practical and valuable observations were listened to with the closest attention. At the outset he particularly impressed upon his hearers who desired to hybridise and cross-fertilise plants, the great importance of selecting good parents for their stock. Speaking as one who had been extensively engaged in the work for twenty years, he explained the most successful mode of fertilising Zonal Pelargoniums, Primulas, Begonias, Chrysanthemums, and other flowering plants, and also fruits, more particularly Grapes. He recommended that plants which were being experimented upon should be isolated from other plants, and the hybridiser must not be a lazy person, but should be in operation at an early hour in the morning. If they intended to be successful they must also be methodical, and take notes and keep records just the same as is done by breeders of horses and shorthorns. In concluding his excellent lecture, Mr. Pearson referred to the pride and pleasure it afforded a fertiliser to raise any new plant, flower, or fruit, and said that the names of such men were never forgotten.

- HORTICULTURAL CLUB.—The first dinner and conversazione for the session of 1893-94 took place on Tuesday in last week. There was a good attendance, although several members of the Club were engaged at the United Horticultural Benefit and Provident Society's dinner at the Cannon Street Hotel. There were present the Rev. W. Wilks, Rev. F. H. Gall, Messrs. John Lee, J. S. Cousens, Geo. Monro, J. Webber, W. Assbee, A. Watkins, A. H. Pearson, Geo. Bunyard, T. Francis Rivers, H. Selfe Leonard, and others. The discourse was opened by Mr. Geo. Bunyard with an interesting paper "On the Effects of the Drought as affecting Horticulture, more especially in its Relation to Fruit." An interesting discussion in which nearly all the members took part followed, and from which much valuable information was obtained. Much stress was laid by Messrs. Webber and Monro of Covent Garden on the imperfect way in which fruit was packed for market, inferior fruits being put in and the samples not properly sorted. It was also stated the extreme earliness of the season had completely disorganised the foreign fruit market. As a proof of the extreme fertility of the crop it was stated that in one orchard in Kent 8 tons of Goffs (a second-rate Apple) have been gathered off nine trees. Mr. Bunyard also placed upon the table a large dish of Vicomtesse Héricart de Thury Strawberries gathered from the open air of good size and excellent flavour. He also contributed some dishes of Beurré Bosc and Beurré Fouqueray and Pitmaston Duchess Pears, the two first of which were pronounced excellent, though preference was given to Beurré Bosc; Pitmaston Duchess is universally condemned as worthless in quality. A cordial vote of thanks was given to Mr. Bunyard for his excellent paper, which will be found in another part of our present issue. EXETER GARDENERS' ASSOCIATION.—At Exeter Guildhall last week, Mr. D. C. Powell, of Powderham Gardens, read a most interesting and instructive paper on "Pears and their Culture," in connection with the Devon and Exeter Gardeners' Mutual Improvement Association. Since the establishment of the Association the gardeners of the district have shown the utmost interest in its affairs, and have greatly benefited by the practical and comprehensive manner in which a variety of subjects, especially relating to gardening, have been dealt with. The paper read by Mr. Powell was the first of a series of essays which will be discussed during the winter session. Mr. G. B. Carlile presided over a large attendance.

Sweet Scabious.—Mr. W. H. Divers, Ketton Hall Gardens, Stamford, writes:—"I noticed a fine row of this in full flower recently at Orton Hall Gardens, Peterborough. Mr. Harding had planted it along the front of a Vine border near the walk, where it had a very fine effect, and the plants were carrying a large number of flowers. It has also proved very useful with me this summer for cutting. Most ladies are very fond of it, as the colours blend well together, and if a few of the bunches of seeds are judiciously used with them, it enhances the effect of the flowers. The culture is simplicity itself. All that is required is merely to sow the seeds thinly on a mild hotbed early in April, and plant out in the open borders in May as is done with other annuals."

OXFORD BOTANIC GARDENS.—Mr. W. R. Guilfoyle, Director of the Melbourne Botanic Gardens, recently gave a lecture entitled "Glimpses of Some British Botanical Gardens and Their Conservatories," from notes taken during his visit to Europe. He said, "I saw much during my travels in the way of gardening and horticulture that was really interesting and useful to me." Of the Botanic Garden at Oxford, of which he speaks highly, though only a few acres in extent, he considers it contains some wonderfully fine specimens of rare and beautiful trees. It is the oldest of British Botanic Gardens, having been founded in 1632. A tree of Sophora japonica measures 11 feet 3 inches in circumference of stem at 5 feet from the ground. There are also some noble examples of different kinds of Ash. A Copper Beech measured 11 feet 6 inches in girth. Near the college are two Elms, one 26 feet 8 inches in girth, and the other is 21 feet 6 inches in girth.

TECOMA SMITHI.

At the Drill Hall, Westminster, on the 10th inst. three plants of Tecoma Smithi, from the Royal Gardens, Kew, were exhibited, and by reason of their attractiveness much interest was centred upon them. The plants shown were about 2 feet in height, and each bore a large terminal cyme of yellow blooms tinted with brownish red. An idea as to the character of the flowers may be gathered by referring to the illustration (fig. 52), and it will be readily conceded that this Tecoma is likely to prove useful for decorative purposes, meriting the first-class certificate awarded by the Floral Committee of the Royal Horticultural Society. Tecoma Smithi is a new hybrid, the result of a cross between T. capensis and T. velutina.

FLORAL NOMENCLATURE.

In last week's "Saturday Review," in an article on flower names, I came across the following:—"Gladiolus (Gladiolus, ma'am, not Gladiolus, as some use, or Gladiolus, as others) is perfect," &c. I presume there can be no doubt that this (with the four vowels all short) is the correct form, notwithstanding the use of the others. Granting that the pronunciation of a Latin word used as a plant name may be occasionally altered by custom, that does not affect the case, as the controlling custom must be consistent; here we have two conflicting customs. Personally, I find it rather goes against the grain to call the plant either Gladiolus or Gladiolus, though I am content to do so if the world at large will only consent to adopt one or the other. Of course I should prefer the world adopting the correct form, but I fear the fourshort vowels are a feeble minority and must submit to be driven in the way in which they should not go. Will you kindly exert your influence to obtain an authoritative declaration of the mode of pronunciation to be hereafter adopted, with a proviso that such declaration shall be not open to change?

As I am on the subject of plant names I will ask permission to go on and protest against the use of Latin plurals that has grown up of late. It began with names ending in us; I have seen it extended to others ending in a, and there seems no reason why it should not creep on to um, and so to the Greek derivatives in is, ma, and ops or opsis, &c., if it has not already done so. There are nurserymen's catalogues that may give a hint of the glorious confusion into which plant nomenclature may fall. The pages of your own Journal (please do not suppose I am attacking the Editor) will furnish an illustration. It is not many months since I noticed in it a report of a Narcissi Show. I can point to

other rather conspicuous instances, but shall not do so. There is one, however, that is not horticultural, so there is little danger of offending any of your readers. Some five or six years ago I picked up a novel in which the author wrote of Omnibi! It shall be nameless, if for no other than for the very sufficient reason that I have forgotten its name.

ever their origin, when adopted for everyday use] without alteration are to be taken as incorporated in the English language, and to be treated for all purposes as English words, and that they must therefore be subject to the same modifications as other words of similar terminations.

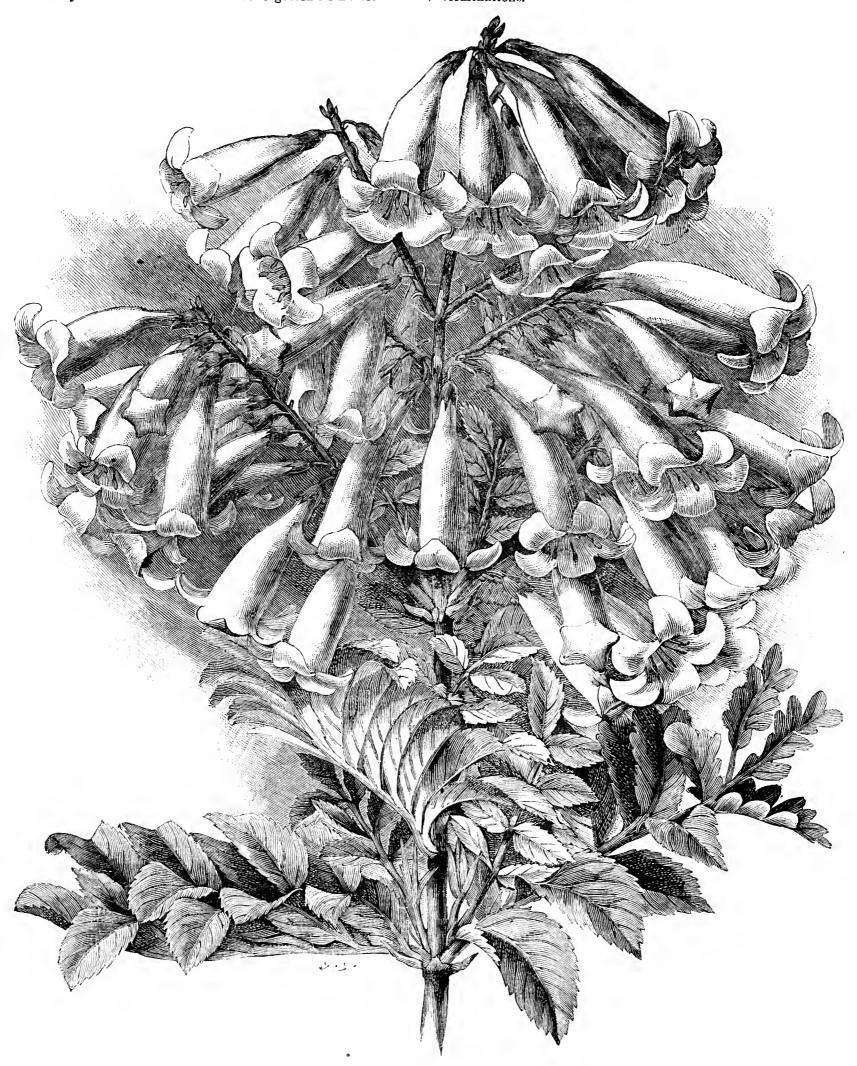

Fig. 52.—TECOMA SMITHI.

It is clear to me that in these cases we should have had Narcissus and Omnibuses but for the bad example of a few men with a prejudice against the agglomeration of sibilants in a plural of the latter form (though how they would get out of the difficulty in the case of the "buses" I cannot conceive; their knowledge of Latin would hardly admit of a resort to "bi").

With all duc deference to them, I submit that names of plants, what-

In a few instances the sibilant plural may be somewhat cacophonous, but do you really think such a word as "Croci" is more euphonious than Crocuses, leaving alone the trap for the unwary you set in the second "c" of the former? I do not. We have reached Nemophilæ. I saw it in the Journal. We have not yet had Rosæ shows, but we shall do so if somebody does not interfere. Do support my protest, and enable me to sign myself—A GRATEFUL OLD SUBSCRIBER.

HOT SEASON ROSES.

THE past season has offered a good opportunity for taking notes of such Roses as may fairly be called by the above title, and I think the general opinion would be that while some have fairly lived up to or even beyond their reputation, others have given disappointment. Though it certainly has been a hot and very dry year, it seems to me, from general impression and not from observation of the thermometer, that hot nights have not been many compared with those of some past years. The general idea is, I think, that a hot and dry year is favourable to the light H.P.'s, but causes the dark ones to "burn," and that a cooler and duller year is therefore best for these latter. I am not at all sure that the "burning" or browning of the petals of dark H.P.'s is caused by bright hot sun, or at least by this alone. At all events, it is worthy of notice that I have in other years, at times when "burning" has been prevented soon bads which appears to the same brown noted. has been prevalent, seen buds which opened with some brown petals even in dull weather, and that during the past season I had not, to my remembrance, a single brown petal among all my dark H.P.'s. I should like to hear what others may have to say on this subject. If caused merely by the sun, why should one or two petals alone turn brown in a Rosc, while others remain of the normal colour? With me the dark H.P.'s were quite good this year, and some of the old fashioned light coloured ones were not successful.

Of generally reputed hot-season Roses, Marie Rady was most disappointing; the blooms "came" badly altogether. It is quite a different Rose with me now, being not nearly so reliable or good in colour as it was ten or a dozen years ago. Monsieur Noman was good, but all over long before show time, as it is quite one of the earliest. Pierre Notting was decidedly better than usual; it opened freely, but was as late as ever. Reynolds Hole was magnificent, better I think than I have ever had it; it often "burns" badly, but I did not see a discoloured petal. It is generally late, but this year was quite early, before many others, and even on maidens was all over before the shows began. Waltham was disappointing, and came to no good in the first crop, but produced unusually fine blooms, good enough for any show, in

September. Duchesse de Vallambrosa and Madame Lacharme are two fineweather Roses, which used to give us a good deal of anxiety; but neither of them with me is worth growing for show now, except in quite large collections. The latter was simply extinguished by Merveille de Lyon, which at once surpassed it on all points, and superseded it altogether. Good old Général Jacqueminot is a thin-petalled Rose, but with me it is decidedly better in hot seasons, being better formed and even more lasting at such times. Some extra full or even coarse Roses were, as might be expected, better than usual. Paul Neron and Mr. James Brownlow were well shown, and I had some presentable blooms of Madame Hippolyte Jamain. Mrs. Paul delighted me in the early part of the season with perfect show flowers, but a little later, when there were some shows at which to exhibit them, the blooms were quite shapeless. This seems to be absolutely a summer Rose. I have not, this year or last, on maidens or cut-backs, seen a single autumnal bud. Madame Gabriel Luizet had more autumn blooms than usual, but François Michelon showed no improvement in this respect.

For Teas it has been an ideal season, as these Roses require drought even more than heat. Unfortunately of late years thrips have become a most serious pest in my neighbourhood, and in a really dry season they spoil an immense number of blooms. I consider they do more injury than mildew, and are very much more hurtful than aphides or orange fungus. The end of September and beginning of October my Teas (though of course rather small) are, I think, in some varieties distinctly better than they were in the height of the season, the thrips have disappeared, each bloom is clean and well shaped, and the colour is extraordinary. I have had Marie Van Houtte with the yellow as deep as Perle des Jardins, and the pink charming; and The Bride with splendid pink outer petals as decided as in Mrs. James Wilson. I take this to be the result of cooler and duller weather without rain following close after dry heat, which seems to be ideal weather for the perfection of all Roses. I do not know whether those who grow Roses in pots under glass move them into a dry and cooler house for the actual blooming, but such a course seems to be indicated.

Of reputed hot-weather Teas, Comtesse Panisse was very large, but much wanting in colour at midsummer; it is very different now. Jean Ducher at least reminded us of what it might be under favourable circumstances; but I was unfortunate with my few plants, which gave me nothing really good. I have one in my memory which gained the amateur medal at a national show at South Kensington several years ago, but I have seen nothing like it since. La Bouled'Or was very good, and opened well, too well on a south wall. Madame Margottin was a hopeless victim to thrips, but gave some fair blooms later.

Etoile de Lyon is a poor Rose with me at the best of times; if anything, it was worse than usual with me this year. My dwindled stock of it will be still further lessened. Madame Willermoz certainly comes but rarely of good shape; but I had one grand bloom, very large and

fine, with a perfect point in the centre. This Rose, and Mrs. Paul, remind me of the little girl in the nursery rhyme—

"Who had a small curl on her forehead :-When she was good she was very very good, But when she was bad she was horrid."

-W. R. RAILLEM.

ROSE ANALYSIS, 1886-1893.

THE friendly criticisms of Mr. Grahame and "Y. B. A. Z." (page 331) are very welcome, as they enable me to offer a few explanations as to the considerations which have guided me in framing the two tables in my last analysis. I must also thank them for the kind words of encouragement they have given me. There is one sentence in my analysis which both my critics appear to have overlooked, and it is a most important one. It is that in which I explain that all the averages "have this year been recalculated on similar lines to those followed in my last Dahlia analysis." I therefore refer them to page 247 of the last half-yearly volume of the Journal of Horticulture, where it is stated, among other things, "that the claims of each variety, whether new or old, have been decided entirely on its merits."

When I first began this kind of work and for some years afterwards, there was nothing left for me to do but to take the number of times the different varieties had been staged in the prize stands, and to calculate from them the averages which govern their respective positions in the tables. But as years went on I began to see that a purely arithmetical process was in many cases very misleading.

1, In the first place I found that certain old favourites were being more or less superseded by better and newer sorts of a similar colour. As to this difficulty the plan now adopted will be found explained, and examples given in the Dahlia analysis just referred to.

2, Exceptional seasons also often play havoc with certain varieties while unduly favouring others. Consequently, when calculating the averages for varieties seriously affected in this way the number of times they were staged under such exceptional conditions has to be omitted. Otherwise, as "Y. B. A. Z." has pointed out, they would stand either higher or lower in the lists than they are entitled to.

3, Then the newer sorts gave me some trouble at first, but a little consideration soon showed that if they were to appear at all in the tables, and they can never for some years hope to compete on anything like equal terms with their more largely grown brethren—the established kinds—they must find places in accordance with their doings at the most recent exhibition alone.

4, Then, again, the varying number of Roses tabulated each year was found to have a more or less disturbing influence. But this difficulty has been easily got over by calculating all the averages as for a show, or rather analysis, of average extent. I say easily got over, but of course all these recalculations each year involve a considerable amount of extra labour.

As suitable corrections for all the above-mentioned inequalities have been most carefully and impartially made throughout the analyses under consideration, I cannot but regard it as the most practical and reliable of the series. However complicated and unreal the system I have adopted and endeavoured to explain may appear on paper, it is in reality simplicity itself, and, after all, only a common-sense way of treating the statistics at my disposal.

In noticing more in detail the apparent flaws and inconsistencies in the analyses mentioned in your last issue, I propose referring my critics

in each case to the foregoing numbered paragraphs.

Mr. Grahame says that I have made a serious error in regard to Gustave Piganeau (1889), also as regards Ernest Metz (1888). If this be so he must be equally wrong in making Ethel Brownlow (1887) spring at once, "literally and truly" as he puts it, into the position at No. 20, because this variety was only staged four times in 1892, and consequently would come out, although the earliest introduction of the three, with an average of 10.5, and therefore only be entitled to a place at No. 26, or not far from the bottom of the table. But in my opinion Mr. Grahame is in this instance, as he says, "literally and truly" right, and if so we must also leave Gustave Piganeau and Ernest Metz where I have placed them in the tables (see paragraph 3). Another year or two will, however, show whether these positions have been as correctly accorded to these youthful aspirants as their performances will allow. In reply to his inquiries I may here state that Gustave Piganeau was shown this year in twelve prize stands by amateurs and in the same number by nurserymen, and Ernest Metz in sixteen by amateurs and in fourteen by nurserymen, Ethel Brownlow seven times by amateurs, and ten by nurserymen.

Mr. Grahame takes exception to A. K. Williams being described in the N.R.S. catalogue as "good in autumn." He says "it is better in the summer than autumn with most people," and so I fancy are most other Roses. If, however, he will refer to page 5 of the catalogue in question he will find the following necessary explanation at the head of the list of Hybrid Perpetuals:—" Where varieties are described as good in autumn' they flower freely a second time." this is more than can be said of many so-called Perpetuals.

As to Mr. Grahame's criticisms on some incidental remarks I made respecting the poor Rose exhibition held by the National Rose Society in 1879, there are undoubtedly, as he says, many more exhibitors now than there were fourteen years ago, and I hope the National Rose Society may justly claim some share in their conversion. But the question is, Had there then existed twice as many Rose exhibitors as at present would there have been a much better show? I am afraid not, for unfortunately no amount of anxious watching on the part of an enthusiastic Rose grower will induce his plants to come into flower if they have not sufficient warmth at the roots to enable them to do so, besides which a very late Rose season generally means late spring frosts and other evils which check the growth of the plants and consequently disfigure the first cut of blooms—the only one available in most districts at anything like an early show, in fact it would have been just like holding our metropolitan show in a backward season during the second week in June. We all know, for instance, what the Drill Hall Show (held June 21st) was like in the late summer of 1891. Therefore, I repeat, sooner or later this must prove our doleful experience at "the National," particularly if an early fixture and a terribly backward season happen to unite their destructive forces in order to ruin it. This is not a matter of opinion at all but of temperature.

Turning now to the friendly remarks of "Y. B. A. Z.," he says, "I have always thought this analysis showed rather the Roses that stood best the test of certain seasons; this has been particularly brought out in the present analysis." Had he made this charge against any of my previous Rose analyses, and it is, I confess, a most natural conclusion to have come to, there might have been some grounds for this statement. He goes on to say, "a season that is inimical to a certain Rose has an effect of a very damaging character on its position for many years." Now this would undoubtedly be the case but for the precautions I have mentioned (paragraph 2). He quotes as an example La France, let me therefore give him the figures from which the average for this popular variety was obtained—35, 27, 33, 38, 38, 48, and 49—average 38·3. Had, however, the values for the full eight years been taken, instead of those for the first seven, its average would have been reduced to 35·3, still allowing it to retain its present position in the table. But Marquise de Castellane, the other Rose he names, if similarly treated, would at once fall from No. 15, the place now accorded to it, to No. 23.

Is not "Y. B. A. Z." in error in classing Ernest Metz as a sport from Catherine Mcrmet? The plants do not seem to me alike in their habit of growth, the former being a much more sturdy grower. I obtained the date of Cleopatra from that handy little book of reference before referred to (the new catalogue of the N.R.S.), and therefore conclude it is correct. Catherine Mermet, Comtesse de Nadaillac, and The Bride were omitted from the select lists at the end of the analysis as not being, in my opinion, sufficiently good growers to recommend for general cultivation.—E. M., Berkhamsted.

In my remarks on this in your last issue (page 331) there is a printer's error. In the cighth line it ought to read, "I cannot fancy that any exhibitor would prefer Ulrich Brunner to Marie Baumann."—Y. B. A. Z.

MESSRS. VEITCH & SONS' LANGLEY NURSERIES.

It is not so many years ago since Messrs. Veitch & Sons established themselves at Langley near Slough, in order to extend their fruit ground and go in extensively for home-grown seeds. They commenced with about 30 acres and now have 70, and judging by the half-worked brickfields all around, the time will come when the land will be worth a great deal more than the astute Chelsea firm paid for it, though it is quite possible that as it is first rate fruit soil and answers its purpose well, the brick speculators will have to do without it when the time comes for them to attempt its acquisition. Land that makes good bricks generally grows good fruit, and one has only to glance over the nursery stock to see that the present case is no exception to the rule.

stock to see that the present case is no exception to the rule.

The Langley Nurseries are easily reached. Fast trains from Paddington run to Slough in a little over half an hour, and the grounds are seen from the line not long before the station is reached. Perhaps they are a mile away on the line side, and about double the distance round by the road. Travellers up and down the Great Western must find much to admire when the broad stretches of trees are in blossom, as well as later on when the herbaceous plants and annuals come into bloom. Probably also they note the handsome and substantial dwellings dotted here and there, and think, which is undoubtedly the case, that the Veitchian nursery is a model one and in every respect worthy of the great firm.

SEED-GROWING AND SEED-CLEANING.

Many acres of the Langley Nurseries are devoted to seed-raising, choice stocks of both vegetables and flowers being grown there. At the present season cleaning is in full swing, and a good many hands were employed in thrashing Peas, cleaning Beet, and picking over flower seeds. The samples are just such as a seedsman would delight in, and the quantities are surprisingly great when it is considered that they are sold retail by the packet and ounce, and not wholesale by the pound and hundred-weight. There are, for instance, about 20 bushels of Crawford's Beet, an excellent sample of seed, and still more of the popular Dell's, which is the most in demand of all. Then there are large quantities of Veitch's Mammoth Runner Bean, and amongst flowers miniature Sunflowers, Tagetes. Marigolds, Tropæolums, and hosts of others. Seed-growing and cleaning has grown to be quite a large business there, and the policy of securing home-grown stocks is found good, not only because of excellent samples being secured, but also in respect to accuracy of nomenclature.

Roses.

The Langley Nurseries are, as hinted, extensive, and the departments are many. The Roses form a great feature. As many as 24,000

Manettis and Briars have been budded this year, and that does not represent all the propagating, for other stocks, notably the De la Grifferaie, are also employed. The last named is found to be better than the Briars for many Teas and Noisettes, and is being used more and more every season. The quarters look wonderfully well considering the dry season, and it may be noted that the nurseries have had to bear the brunt of the drought, the hills and woods not far away splitting many storms that promised to moisten the thirsty soil. There was hardly rain enough to lay the dust from February to the end of September, so that it can be easily understood how trying the season has been, and what great efforts have had to be made to keep the stock "up to the mark." It has been done, as anyone can see who cares to go.

ORCHIDS AND PLANTS.

Here enters Mr. Seden. The fogs got to be too much for his hybrids at Chelsea, and so structures have been put up for him at Langley, together with a commodious residence near by. At home amongst his millions of seedlings he ought to be happy, and if appearances go for anything he is. So are the plants. Of seedling Cattleyas, Lælias, and Cypripediums, together with bi-generic hybrids, there are immense numbers, modest-looking now in the early stages of seedling-hood, but destined to occupy proud positions later on no doubt. One beautiful hybrid, a cross between Cattleya Bowringiana and C. maxima, named Chloris, was in bloom, and has since been certificated by the R.H.S. It was sown in 1886, and flowered last year, promising to be a remarkably free bloomer. The rich magenta carmine lip and the golden veining in the throat are very noteworthy. Another Cattleya named Phiedona, a cross between C. intermedia (pollen parent) and C. maxima, was also flowering, and has since received an award of merit. It is, ivory white veined with pink, the lip narrow and flattened at the base ivory with magenta veins, and the throat tinged with gold. Its pleasing appearance, its period of flowering, and its delicious Honeysuckle-like fragrance, combine to make it a valuable form. An ivory-like Cypripedium named Cleola, a cross between C. Schlimialba and C. reticulatum, is also a gem. It is a near approach to white, and flowers up the stem like the valuable Sedeni candidulum. There are other novelties, which will doubtless be produced anon. Phalænopsis are splendidly grown, and so are Disas.

A word must be said about the new Veronica Purple Queen, which was certificated not long ago. There is a fine stock, and judging by its bushy free-flowering habit it should prove a great acquisition for market work.

STRAWBERRIES.

Exit Mr. Seden, enter Mr. Morle. The chief of the fruit department. who acted as guide from London, lives at Southfields, Fulham, where the great bulk of the trained trees are grown, and he is a master in their management. He has a good lieutenant at Slough, and the stock there bears the same impress of quality and skilful management as the magnificent material in the London nursery, which is the highest praise anyone could bestow. There are some Strawberries left yet, for many buy and plant at bulb-ordering time instead of earlier in the season. Mr. Allan's trio are very highly thought of. Empress of India is a fine grower with British Queen flavour, and ready several days before the royal sort. Lord Suffield and Gunton Park are also good growers of high flavour and force well, besides being firm enough for travelling. These should be tried. Dr. Hogg, another Strawberry much esteemed, is well represented, and so is King of the Earlies, as well as all the older sorts. Waterloo is strongly recommended as a late variety that stands the sun well. It should not be picked when red, but left till it assumes the rich purplish hue which denotes perfect ripeness and rich flavour.

LARGE FRUITS.

There are many acres of Apples, Pears and Plums, all the leading sorts being largely grown, and they are in the best condition. A large quarter of four-year-old standard Plums is very striking, and so are standard Apples on straight, clean, healthy stems, wanting no stakes to support them. These are as fine a collection of trees as any planter need wish to buy, and so are the three-year-old bush Apples, with Frogmore Prolific prominent amongst them. There is a quarter of pyramids budded on the Crab conspicuous for clean and vigorous growth. Two-year-old standards of Bramley's Seedling are excellent material, and another Apple very noteworthy for its clean, healthy growth and good habit is Beauty of Stoke. This is unquestionably a fine variety, and one that ought to be tried. Apart from its qualities as a grower it bears freely and the fruit keeps well. Two-year-old Bismarcks are ahead of almost everything of their age. Lord Grosvenor, a valuable early Codlin, does spendidly at Langley, its growth being as clean as a well managed Croton and its foliage quite leathery. Young pyramid Pears of the principal sorts with a cordon tree planted between each pair form another impressive quarter.

TRAINED TREES.

Trained trees comprise Mr. Morle's great forte. Every grower should go to Southfields, to see the stock there, and then arrange for another day at Langley. Popular Plums like Coe's Golden Drop, Jefferson, Green Gage, Kirke's, and Victoria are represented in hundreds, every tree a model of good management and cleanliness. Then there are Cherries, such as Bigarreau Napoleon, Governor Wood, Elton, Early Rivers, Black Tartarian, and Archduke, almost as numerous and equally good. High quality Pears like Doyenné du Comice and Marie Louise are grown in enormous numbers. There are more of these at South-

fields, and it is there that the great majority of the trained Peaches and Nectarines for which the firm is famous are grown, so that a visit

to both places should always be paid if possible.

I might add, although it hardly comes under the heading of "trained 'a note about Superlative Raspberry. It is very highly thought of, and is unquestionably a splendid sort, producing abundance of large, richly coloured fruit. There was a large quarter of it, canes put out in spring bearing large clusters of fruit.

FLORAL ASPECTS.

There is a very fine herbaceous border running through the centre of the Langley Nurseries at right angles with the railway which well merits mention, for it has been magnificent this year. The Delphiniums in particular have been superb. Michaelmas Daisies in great variety, Pyrethrum uliginosum, Dahlias, Sunflowers, and Sedum spectabile were prominent amongst its autumnal attractions. Near by, and running parallel with the line, was a dazzling bed which, as being at its best in October, was very noteworthy. It was composed of Papaver glaucum, a dwarf sort with flowers much resembling those of umbrosum. They were of a rich and very glowing crimson, with black interior basal blotches, and glistened brilliantly in the autumn sunshine. The seed was sown in May, and in a little over four months has produced one of the most striking beds imaginable. On the walls of one of the houses Cratægus Lelandi, so much superior to Pyracantha from its bearing far more freely in a small state, and Lonicera japonica (brachypoda), a

sand, or charcoal. Wherever the pipe is under ground, and not in a trench, it should be covered with felt or pipe cement, made from hay or hair one part, horse droppings one part, and clay two parts. The hay or hair must be well worked with horse droppings into the clay, and the mixture thus formed should be placed 11 inch thick around the pipes. This cement will keep in the heat, also prevent the pipes from rusting, which they will surely do when simply buried in the earth. A portion of the radiating pipes should be placed in such a position that the air on entering the houses is warmed before it reaches the plants. "Dips in the pipes at any point should be specially avoided, as they often impede free circulation."* "In each house on the highest points of the pipes must be placed air-vents. This is an important point, because air being lighter than water it will certainly rise to the highest point; and as air in the pipes can never be made to pass downwards, no matter how small the extent, the reason for having air-vents at the highest points is at once demonstrated." † (The quantity of 4-inch pipe required for a house is easily ascertained by referring to a method of rapid calculation by F. Dye, the writer of "Hood's work." He bases the figures on the quantity of glass per 1000 cubic feet internal space. The figures, which are approximate only, conditions and positions varying, are intended for lean-to houses, with one side of brickwork. If

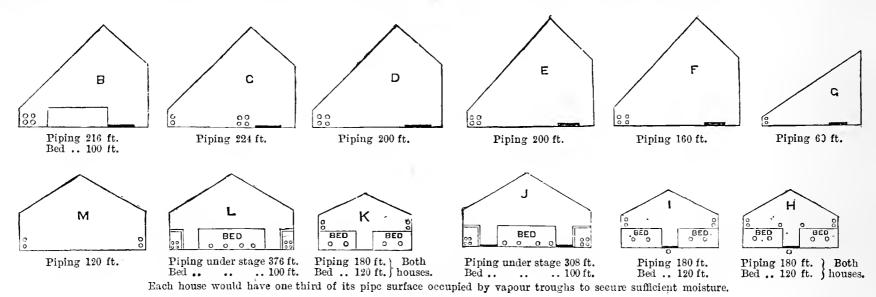

Fig. 53.—SECTIONS.

delicious Honeysuckle blooming nearly all the year, produced welcome fragrance and colour, and served as pleasant reminders of the past glories of this wonderful season.

PAST AND PRESENT WORK.

The fifteen years or thereabouts which have elapsed since the Langley Nurseries were established have seen great changes. Then under the charge of the veteran Newby, who has long since passed away, 30 acres of land were gradually cultivated and filled. Now 40 acres more have been added, and the whole of the ground is closely planted. A fresh piece of 4 acres is being broken up for seed trials, chiefly vegetable, to take the place of the ground at Chiswick, which has now fallen into the builder's hands. Thus the order of events is progress and development. For the general order and cleanliness observable credit must be paid to Mr. Scott, the general manager of the nursery. Probably much of Messrs. Veitch's colossal success is due to their wise and judicious choice of departmental heads, all of whom are courteous, capable, and energetic.—NOMAD.

THE PRINCIPLES OF HEATING:

INCLUDING THE ARRANGEMENT OF HOT-WATER PIPES FOR (a) FRUIT HOUSES: (b) FOROISG HOUSES WITH BOTTOM HEAT; (c) BEST KINDS OF FUEL, WITH THE MANAGEMENT OF FIRES, AND THE REGULATION OF TEMPERATURES.

Silver Medal Essay by MR. HARRY CORLETT, Foreman, Woolton Wood Gardens, Liverpool.

(Concluded from page 329.)

(3), THERMOMETER.

THIS is a necessary instrument in every garden, and it is the only unfailing guide for the gardener in regulating the heat of his houses. The self-registering thermometer is the best, as it gives the maxima and minima temperature of the atmosphere outside, or the temperature inside our houses during a given number of hours. There is also the bed thermometer, which is enclosed in a wooden or metal tube pointed at the bottom, so that it can easily be inserted in the bed to ascertain the heat therein.

(4), PIPES.

The main pipe, which is under ground, should be laid in a brickwork trench, and covered with a non-conductor of heat, such as sawdust, spar-roofed, position not much exposed, add one-fifth to the length of pipe given. Heat of pipe being 180°.) It is always wise to provide for emergencies by having a sufficient quantity of pipes in each house, fitted with valves in the flow and return pipes.

‡ F. DYE'S TABLE. Quantity of pipe to each 1000 cubic feet. Purpose for which the Temperature required. house is intended. 90° Fahr. Forcing houses. Melon pits. 60 ,, 55 ., 50 ,, •••••••• Grapes & Stawberries. 45 ,, 40 ,, 37 ,, •••• •••••• Fruit trees. Outside temperature 10°

(5), BOILER.

The forms of some of the newly patented boilers are so very complicated that they are sometimes not so effective as those of a simpler character. The principal thing in selecting a boiler is to choose one with the greatest surface of exposure to the direct action of the fire, combined with the tested heating capacity, at a given cost. For our purpose a terminal end saddle boiler would suit admirably. In choosing a boiler, no matter what size, the one selected should be about 40 per cent. more powerful than is actually required, as such will last much longer and work better. After the boiler has been put in its position, it should be covered with the best available non-conductor of heat, such as charcoal or sand; a case of brickwork with sand or pulverised charcoal between this and the boiler is to be preferred.

(6), FUEL.

What is the best fuel to use for horticultural purposes? is a question often discussed. Undoubtedly I would recommend anthracite coal because of its many good qualities; failing to procure this I would advise coke before ordinary coal. The reason I claim anthracite to be the best

^{*} Hood on Warming Buildings, 6th edition, page 69. † Hood, 6th edition, page 47. ‡ Hood, 6th edition, page 245. Published by E. & F. N. Spon, 125, Strand, London.

can easily be ascertained by comparing the different qualities of anthracite, coke, and coal. For instance, ordinary coal can only be used extensively where the gardens happen to be in close proximity to a colliery, it being cheaper then than having to send away for coke or anthracite. This is the only really good point in its favour. Now look at its disadvantages. It is almost unequalled for throwing off a dense smoke, highly charged with gases detrimental to vegetation, also producing much soot, which generally drops on the roofs of glass structures, or alighting on the leaves and flowers of plants in the houses as soon as the ventilators are opened, thus giving them an undesirable appearance. Then look at the filthy state of the flues and chimney; notice how often the flues are choked, thus costing considerably more labour, in cleaning than is required by either coke or anthracite.

The next to be considered is coke. As a heat producer I put it on a level with anthracite, but its great disadvantage is the amount of labour entailed in stoking compared with that of anthracite. Coke, moreover, is so very porous that it will absorb a very large quantity of moisture if kept in the open air, and this moisture must first be dried before it can give any chance for the coke to become ignited. Some people have an idea that coke burns much better if watered. This to my mind is a serious mistake, for watering the coke decreases its heating power. If water was put into the ash pit it would not only cause the fire to burn clearer and brighter, but also utilise the heat that is radiated downwards from the firebars. There are also the sulphur fumes, the continual visits to the stokehole, attended by the necessary clinkering and poking, this meaning more waste, viz., clinkers and ashes. Then look at the short time a coke fire will last compared with one of anthracite, thus wasting valuable time.

The points by which anthracite predominates over other fuels for horticultural purposes are greater durability, less labour in stoking, perfectly smokeless, and less sulphur fumes. A fire may be banked up at 6 P.M., and it will not require touching until noon the next day; this proves its durability. There is less of that continual poking required, therefore less labour in stoking. Scientists assert that the heating power of any fuel is approximately proportionate to the percentage by weight of the carbon it contains, therefore anthracite containing 90 per cent. of carbon heads the list. Of course there are disadvantages, but they are not so great as those attending coke or coal. There is the price to be considered; certainly it is dearer than coke or coal, but 2 tons of anthracite are of more value than 3 tons of coke or coal. Then some persons dislike the working of it, but this very often is the fault of the stoker and not the fuel. All that is required in stoking with anthracite is described under stoking.

(7), STOKING.

Having the desired fuel at our command the system of stoking must be considered. How many failures have there been? How much damage has been done? through the total absence of any desire to become a stoker in the true sense of the word. Why this ambition is so seldom met with is to me an unsolved problem. According to my experience only two gardeners out of every twelve have any real heart in this part of their work.

As I advocate the use of anthracite I will give a simple method of stoking with it, which may be brought into daily use. The first thing required is a thorough draught, and therefore the firebars, flues, and chimney must be kept clean. At midday allow the fire to burn very low, and after removing the clinkers thoroughly clean the back of the boiler and firebars, then push the clean fire towards the back of the boiler; put on a little fresh fuel, which should be broken to the size of a teacup, and not placed on the bars in too thick a layer. After opening the ashpit door, and carefully working the damper, allow the fresh fuel to be thoroughly burnt through before any more is added to it, and if by this time the desired heat has not been obtained add more fuel, keeping the poker out of the fire, except it be to remove the dust on the bars. When the required heat has been secured regulate the draught according to the weather. At banking up time push the majority of the fire to the back of the boiler, and fill the front portion with fresh fuel. By pushing the fire to the back the heat is regulated, while the fresh fuel is getting ignited. The fire may then be left with safety until the morning, and if there has been no marked change in the weather it may be checked until afternoon. Of course the discretion of the stoker will allow him to know whether the fire should be started in the morning or not, but the chief point for him to watch is to keep a clean, fire without the continual use of the poker. What little ash there is in the ash-box should be removed every afternoon when the fire is started, and water to the depth of a couple of inches be put in its place, the advantage of this being already pointed out.

(8), STOKERS.

The task of a stoker is truly momentous, and a few remarks on his duties may not be out of place. Let the student observe these rules-(1) Cleanliness, (2) use discretion, (3) study the weather. No stoker should visit his fire without knowing the temperature of the houses; the temperature of outside air; the direction of the wind, noticing of course which houses suffer most; the changes that have taken place in the weather during a certain number of hours; and then calculate what will be most likely to happen next, and work his fire accordingly. He must be careful that the flues and chimney are kept clean, also that the feed cistern always contains clean water. One very important point for him to watch is, he must not have too much fire heat in the houses, as more than sufficient heat is not only waste, but the plants get drawn and dried. He must keep his valves in good working order, so as to be in readiness in case of any unforesecn occurrence. As a general rule the above will prove the qualities of a person wishing to become a stoker, and it is here, in the stokehole, where the character of a man, no matter

FIG. 54.-MR. H. CORLETT.

whether he be young or old, is unconsciously, but truly, displayed, for should he have an untidy stokehole he is bound to be the same at his work; but if, on the other hand, he keeps a clean stokehole, then he will be quite as neat and clean in any other work he has to perform. This latter qualifying point is one of great importance if he be employed in a private garden.

[We have pleasure in publishing a portrait of Mr. H. Corlett, and congratulate him on the general excellence of his essay.]

HARD COLD WATER FOR PLANTS.

I AM afraid my young friend and former pupil Mr. Dunn (page 317) is going to get the worst of the cold water argument, as weighty evidence seems to be forthcoming against him. Soft water, or that which has been exposed to atmospheric influences for some time, not being available in ninety-nine gardens out of every hundred, the best must be made of the cold water at our disposal; but that is no argument of its being better, or even so good, for plants in general, as is water that has been softened and warmed by exposure. Which of the two is best? Which would cultivators prefer if they had the choice?

The use of tap and well water during the hottest months of the year

The use of tap and well water during the hottest months of the year does not, as a rule, show any evil results; but we must draw a line, or the use of cold hard water, recommended as it is being done, may end in the ruin of many plants, Would those who are advocating the use of cold hard water use it direct from taps and wells during the winter and early spring months, when the temperature of the water would be 20° lower, more or less, than the house in which plants or fruits may be growing? If the advocates of hard cold water do this, then I must join with Mr. Dunn and condemn the practice.

I cannot bring my mind to believe that Mr. Molyneux, or the other able cultivator taking part in this discussion, would think of using water direct from taps and wells for Crotons growing from October to

the end of March in a temperature of from 60 to 65°. What would be the result? I am afraid the plants would not long remain satisfactory. Who would be mad enough to supply winter Cucumbers with water 30° lower than the soil? The subject is a wide one, and appears to me to need more thought and consideration than your correspondents are bestowing upon it. Cold water used in a reckless manner would be a barbarous system of treatment that would soon bring about a condition of growth that would be miserable in the extreme.

Force Roses early in the season, and try this cold water business. Mildew will soon appear; continue the practice, and it will spread like

magic.-W. BARDNEY.

I HAVE no wish to pose as an authority upon this subject, yet I claim the right to question any evidence that is brought against my own opinion, and if after a thorough investigation that evidence is strong and convincing, I am ready to submit, withdraw, or retract. In this case the evidence is without any recognised authority, and "J. B. R." quietly surmises that the authorities I quote would not venture to support their own assertions. Does he call this argument?

Whilst in conversation with one of our leading nurserymen a few days ago the question of the past summer's water supply naturally arose, and his experience of "hard cold water" was limited to one word—

" bad."

I fully appreciate the support which your correspondent "T. A." (page 340) accords me in this discussion, yet I cannot altogether agree with him as to "hard water" minus cold being only injurious; it is the chilling effects upon the young hair-like roots which in my opinion causes injury to the plants, and this combined with the salts of lime contained in "hard water" is the more disastrous. Upon the estate where I reside there are three separate supplies from wells situated about a quarter of a mile apart, and the water drawn from each one differs materially in hardness. This is not the only neighbourhood or county in which I have watched carefully the effect of "hard cold water" (drawn direct from springs) upon vegetation. Therefore I claim that it is not in one particular county more than another that "hard cold water" proves injurious, although I admit it may in some districts act more quickly than others; but taking the country throughout vegetation in my opinion cannot flourish (in the true meaning of the word) when constantly watered with spring water in a cold raw state.—F. DUNN.

NEW CARNATIONS AND PICOTEES.

In the Birmingham districts there are several excellent cultivators of the Carnation, and in no other locality can more select collections be found. During the past summer I have had repeated opportunities of seeing some of these collections, notably those of Messrs. Thomson, Sydenham, and Brown, and as a large number of Carnation growers are readers of the Journal I send you notes of the opinion formed of these flowers.

CARNATIONS.

Lovely Mary (Lakin).—Very bright rose flake, pure in the ground colour and well marked. A flower of fine form and first-class quality.

Claudian, s.f. (Thomson).—This has great breadth of petal, clear ground, the colour very bright, and is of the finest form.

John Payne (Chaundy).—Good in form, but the ground colour is not clear, and the marking is not good.

Mrs. Douglas, P.F.—Has broad, regular, rosy purple flakes and pure

ground colour, good petal and fine form.

William Dean (Chaundy).—A very promising scarlet flake, and finer than Guardsman sent out at the same time by the raiser. It is rich in colour, has a fine petal, is perfect in form and is an excellent grower. It was first also in the scarlet flake class at Oxford.

Agricola (Douglas), P.F.—Clear ground colour, with broad bright

purple flakes, and a first-class flower.

Plate (Thomson).—A bright P. and P. bizarre. A full-sized flower in the style of Rifleman, but of a different shade of pink colour. A very fine flower in breadth of petal, form, and substance.

E. G. Wrigley, P. and P.B.—Beautifully marked, pure ground colour,

broad petal, large size, and of fine form.

Guardsman (Chaundy).—This was a fine scarlet flake as shown at Oxford as a seedling, when it received a certificate; but in the midlands has been very disappointing this year, coming too much coloured and rough in form. Occasionally it has been seen good, as in Mr. Edwards's stand at Oxford. It will, however, be grown again.

Mrs. May (Dodwell).—Pale rose flake, pure ground colour, good

petal and form; a free grower, and a fine flower.

Harmony (Douglas), P. and P.B.—A fine flower in the style of Sarah Payne, but paler in colour, also a good grower.

Lord Salisbury.—A seedling raised by Mr. J. P. Sharp, the veteran raiser of Picotees Mrs. Sharp, Campanini, Scarlet Queen, Rosie Sydenham, and others. A very fine crimson bizarre of large size and excellent

quality, very bright in colour.

J. P. Sharp, s.f. (Thomson).—This was exhibited for the first time at the London Exhibition of Carnations and Picotees, and was awarded a first-class certificate. It is a fine flower, but cannot be sent out until

Ellis Crossley (Geggie), P. and P.B.—Bright, clear, and well marked, with fine broad petal of good substance, and a grand all-round flower.

Mrs. Smith (Geggie), P. and P.B.—A light coloured flower of good

quality and size.

Mr. Yeadon (Geggie), S.F.-A large flower with very broad petal, bright in colour, and a most promising new variety.

Tom McCreath (Geggie), S.F.—A flower of good size with medium-sized petal, which is well marked with dark scarlet.

Forhunter (Geggie) .- A very good flower, much like Sports-

man, and a stronger grower. Flamingo (Barlow), S.F.—Of medium size and bright, with a good

white ground.

Billy Henderson (Geggie), P.F.-A large full flower, clear ground

colour, and well marked with deep purple; a decided acquisition.

Mrs. George Cooling (Hooper), R.F.—A grand flower, large, smooth, well-formed petal, and a variety which will be in the foremost rank of rose flakes.

Rosy Morn (Geggie), R.F.-A large flower, very bright in colour, but with an impure ground colour.

Tom Wood (Geggie), R.F.—A superb flower, broad petal, clear white ground colour, and resembling Sybil.

Lady Mary Currie (Douglas), R.F.—A very large and full bloom, not so bright in colour as some, but it is of a very pleasing soft rose shade of colour, and fine in petal and form.

Tom Pinley (Geggie), s.F.—This flower was dull in colour about Birmingham, but as shown at Manchester was very bright and fine, and

excellent in form and petal.

Charles Henwood (Douglas), P.F.-A grand well marked large flower, with smooth broad petal and pure white ground colour.

Virgil (Douglas), C.B.—A richly marked flower, the white ground pure, of fine form and very promising.

Mr. Tom Lord is sending out four new varieties-Duke of York, Bruce Findlay, Thaddeus, and Arline. The latter is a most promising flower, and I give the following opinion by a good judge who has seen them. He says, "I consider Arline (P. and P.B.) the best I have ever seen, broad smooth petals, very clear white and rich in the marking, very much like Sarah Payne at her best, but an improvement on it, which is saying a great deal. Bruce Findlay (C.B.), is one of the largest flowers in cultivation, and has not a small petal in it, very pure in the ground colour and richly coloured marking; a splendid flower. Duke of York (S.B.) is a large well-built flower of fine form and petal, but the colour struck me as too pale for a good scarlet bizarre. Thaddeus (C.B.) is another large flower, very much like Master Fred in colour and style, but as shown at Manchester was rather rough on the edge and somewhat spotted; but Mr. Lord explained that an accident had caused the roughness, and that it came quite smooth, in which case it will be a fine flower." Mr. George Chaundy of Oxford, who is coming well to the front as a raiser, received a certificate at Oxford for Feron (P.F.), a very fine variety of good size, excellent form and well flaked, with dark purple on a white ground.

The opinion I have expressed as to the flowers named is not given in a dictatorial spirit, but more to draw the attention of amateurs to the newer kinds of Carnations. The season of 1893 was, too, a very trying one for this flower, and every grower could give various opinions of older varieties. On turning to Mr. Dodwell's new list just issued I note that he also introduces some new varieties for the first time; but I have unfortunately not seen them all. Mrs. Rowan is an excellent rose

flake, and Othello should be a very fine S.B. from the description.

Mr. Chaundy has also five new Carnations.

Those florists who are verging upon the threescore and ten years cannot but be struck with the large number of new varieties now annually introduced, compared with what raisers did years ago. I recently turned to a volume of "The Florists' Guide" for 1827 to 29, to have a look again at an admirable coloured illustration of Cartwright's Rainbow (C.B.), a flower which had a great popularity for a long number of years, and in the same volume is a well preserved plate of Strong's Princess of Denmark, which many will remember. Our florists of the present day are careful hybridisers, and such desirable crosses are effected that excellent results must follow.—W. D.

(To be continued.)

ONIONS AT READING.

I WAS specially privileged the other day to see the very fine Onion bulbs which Messrs. Sutton & Sons have at Reading, as representing the qualities of their newer stocks. That of late years there has been a remarkable increase in the average size of Onions, due both to superior cultivation and to selection as well as of inter-crossing for the production of fine sorts there can be no doubt, and although there may be differences of opinion as to the value or usefulness of these huge bulbs when obtained, yet there they are and as such they command admiration. Whilst most of the sorts—and some have bulbs of more moderate size, simply because no form of cultivation can make them unduly large—are represented by fine samples, all very clean and handsome, there is about the collection a feature of unusual interest, and one too much kept out of sight by many Onion growers; good examples also of the produce of the varieties as found under what is so well known as ordinary cultivation. It seems to be proper and honest to show the public what sort of bulbs these newer varieties will produce under what may be termed extraordinary cultivation, and also what is the average product of ordinary culture, as then no one is misled.

It is very doubtful whether we should ever have heard of the large

show bulbs of to-day but for the offering of prizes for them. I could not but be struck with the exceeding beauty with moderate size found

in such splendid stocks as Sutton's Globe, one of the firmest, handsomest, and most perfect brownish yellow skinned Onions in commerce, and in the slightly smaller, but if possible, more even and handsomer Crimson Globe. To my mind these seem to be the perfection of show Onions, hard as bullets, keeping for many months without waste, and large enough for anything. A very superior Onion of a broad flatter character, but with a deep base that makes it weighty, is Sutton's A1; and there are of the brown or almost reddish brown Spanish type some seedlings from a famous Hampshire Onion grower that bid fair to make some of the very finest Onions in commerce. Ailsa Craig is here from the original stock sent out years ago by a well known Scotch house, and which growers generally admit to be a remarkably pure and perfect stock. That result, however, is but the product of that close, keen, capable, and incessant supervision which Messrs. Sutton & Sons give to everything they grow, and which only firms of such position can give.

Onions are very erratic, and can be kept true to form only when the stocks are most rigidly selected and rogued. It is because of lacking this supervision that so many complaints have come to my knowledge of stocks sent out to customers at abnormal prices have proved to be so disappointing. Sutton's Exhibition is another very fine broad variety, looking like a vastly improved form of the Reading, for from all the old and once popular Onion stocks we are now a long way ahead. One great gain arising from them, apart from their capacity to win prizes, the which is, after all, but a poor matter, is that under ordinary culture the weight of crop is about 30 per cent. increase over that of the Onions of twenty years since, and when really good stocks are obtained, the ground is good and free from maggot, there can be no doubt but that even at 3s. per bushel Onion crops may be obtained worth from £80 to £100 per acre, and what other crop can excel that in value? There were also in this collection of Onions two that are of especial beauty and quality for summer bulbing—that is, of course, from autumn-sown seed. These are the handsome tapering Lemon Rocca and Sutton's White Globe. Although in this case these have been grown from spring sowings, yet these, as is the case with all the Tripoli or Italian section, are best for autumn sowing. The White Globe, being so much deeper and rounder than the Lisbon or Leviathan, should make

a most attractive variety for summer exhibitions.

I have dwelt thus largely upon these Reading Onions because it is right the public should understand that Onion stocks, and especially those of exceptionally fine quality, are of no one person's or firm's inheritance. Messrs. Sutton & Sons have been labouring to produce the very finest stocks of Onions, as, indeed, all other things, ever since established as a firm, and what is now being done is simply a part of that great work of continuity in selection and improvement to which there has been no break. It is, perhaps, the case that in regard to Onions the firm has been over-modest. In any case, their present splendid stocks show that if modest, there has been no slacking in

enterprise.—ALLIUM.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

As a member of the Committee of the above Society I should like to be allowed to express my gratitude to those gentlemen who all spoke in such an admirable manner at the annual dinner last week, a report of which appeared in your last issue, and with your permission I will

make a few remarks.

The Chairman made an excellent speech, clearly demonstrating the advantages to be derived by gardeners joining our Society. I could hardly agree with him when referring to the rules of the Society. He suggested a graduated scale of payment similar to that adopted by other friendly and insurance societies, so that a member joining at an early age would not have to pay so large a contribution as an older one, because under the existing rules if a young man joins at the age of twenty years, and lives until he reaches the age of seventy, he can then draw his money with the accumulated interest, which would amount to considerably more than double the sum due to another member who joins at the age of forty. It is worthy of note that some of our older members are having interest added to their deposit account amounting to more than their annual contributions.

Mr. Sherwood, who has done such noble work in starting and adding capital to the convalescent fund, made a very practical suggestion when he said gardeners should endeavour to get their employers to subscribe to this fund. I consider it would be to their advantage to support it, because should a gardener unfortunately have a serious illness, when getting better again a change of air might benefit him to such an extent that he would be able to resume his duties weeks sooner than

he could without that change.

The work of the officers and the soundness of the Society was highly spoken of by gentlemen competent to speak on those matters, but Mr. Marshall touched on the weakest point when he spoke of the management fund. The Committee does not feel justified in recommending a further tax on members beyond the payment of their annual subscription of 2s. 6d. to that fund; but if we had 5000 members instead of 500 the annual income to the management fund would be £625 derived from the 2s. 6d. payments, we should then be in a position to provide our excellent Secretary with paid assistance, and adopt other methods of making the Society known throughout the country. The work at present is done in a most economical manner, and the Committee have no power to spend a penny more than is received for the management.

Could not the Gardeners' Mutual Improvement Societies do somc-

thing to help by discussing the objects at their meetings? It is for mutual benefit. The editors of the gardening papers do all they possibly can to make the Society known. No doubt every good gardener reads one or more of those papers week by week, and yet some men say they have never heard of the existence of such a Society. When gardeners join in large numbers and contribute voluntary 1s. per year to the convalescent fund there should then be no cause to make any further appeal either for that or the management fund, and we could look at our motto, "Unity is strength," with much more pride. At present we have in round figures 500 members, and a capital of £8000 invested, or an average of £16 per member.—G. W. Cummins, The Grange Gardens, Wallington.

A WALK THROUGH A DUTCH FLOWER GARDEN.

You dreamt of flower-bells sending clouds of incense up into the sky and over the misty dunes to the turquoise blue ocean. And now the cathedral bells drop their music from mid-air down upon you as you enter the old town. The flower bells fade and vanish when spring and summer are gone; the cathedral bells remain, chanting their hymns summer and winter, day and night. As once again you come to the old town of Northern Holland, it is the song of the bells that greets you first. And listening to it you feel at home.

Dear old Haarlem! not sufficiently fashionable to be oppressive in the autumnal tourist days, but brimful of healthy still-life—what a boon it is to come, in one's manifold wanderings, upon this soothing spot! So easy, too, to reach it from the world's highways in England, and, above all, in London. Truly, it is far more troublesome to go from one side of greater London to the other than it is to go from Liverpool Street to Holland.

From your breakfast-room on board your ship into your drawing-room again, in a train, and look, as you glide along, at pictures of the Dutch school. Ancient and modern they are, at the same time; Rembrandt, the Cuyps and Hals themselves could not have given you them in such perfection as you see them through your carriage windows. Presently, almost too soon you think, you are at the Hague, the delightful Hague with its white streets and palaces, its clear waters, its heroic past, and its unique suburb, sweet old-world Schveningen. Next comes Haarlem, the old town whose history was made 300 years ago. You mean to listen to the voices of the past, as told by the very stones of the Groote Kirk, and by the singing of the bells. But first you must go and see the flower gardens in the midst of which the town is planted.

The Hyacinths have been in their graves these five long months;

The Hyacinths have been in their graves these five long months; the vast tracts of flat sandy soil which they, blooming, caused to look as if the sunset sky had fallen upon the earth, know them no more. The Tulips followed, with their tints of fire; the Pæonies have come and gone; the Amaryllis and all its proud relations are of the past, and now the last of the Lilies are in bloom. The end is near. The stork, the guardian of the bulb field, is on the wing; you look upon it all, and scarce suppress a sigh. Clear water in straight, long canals; grey sand beds, and wafts of pure sun-warmed sea air seem all, at first, in this flower garden at Overveen, just outside Haarlem, owned by Messrs. Ant. Roozen & Son, one of the largest firms of bulb growers in the district. The bulbs are housed during the short period of summer when the Hyacinth and Tulip have been unearthed and shelved in a storehouse which, in its way, is a palace. And when the autumn comes, and the burial of the bulb must be undertaken, the graves in which they sleep are in the loveliest gardens of the Dutch bulb district.

A boat is moored on the canal in Messrs. Roozen's gardens. It is filled with large baskets of bulbs, purple and red and white. Not far off on the sandy beds, the sunburnt gardeners are at work. So, after all, the gardens are not dead. The bulbs are being buried; their most active time begins, for they have to prepare, as soon as the soil covers them, for the great resurrection morning in early April, when their blossoms transform the sandy flats into one of earth's loveliest sights.

"There is a special art in bulb planting, Mr. Roozen, will you tell me how to grow Hyacinths successfully?" "Certainly, I will. It is not difficult nor a long process. Get good bulbs, even though they are a little more expensive than inferior ones. It pays best in the end, and twenty first-rate flower spikes on a garden bed make a better show than twice that number of second or third-rate flowers. Plant your bulbs in good ordinary garden soil, dug up with some inches of well-decayed manure. Then put your bulbs 3 inches under ground, leaving a distance of 5 or 6 inches between them. Put a little sand round each bulb, and cover with soil. That is all, and if you cover your Hyacinth bed during the winter with leaves, straw, or pulverised manure, you will find in March that you have Hyacinths which, for beauty and fragrance, are superior to any other spring flowers."

"Are there any special Hyacinths which are better than others for outdoor cultivation?" "No; we put all the different kinds into one parcel of mixed bulbs, and they are all equally good. But of course some of our customers prefer special kinds. There are a few leading varieties. For instance, if you want a bed of blue Hyacinths in various shades, I should suggest the King of the Blues, Czar Peter, Grand Maître, Lord Derby and Prince of Wales. In red and rose colours, Lord Macaulay, Von Schiller, Gertrude, Norma, Fabiola, and General Pelissier, are great favourites; and the best white varieties are La Grandesse, l'Innocence, Madame Van der Hoop, Mont Blanc, and La Candeur. Then there are a few very fine yellow Hyacinths, such as Ida, Obelisque, and King of the Yellows."

"About the Tulips, Mr. Roozen. I hear there is a craze for Tulips." "I don't know about a craze, but sure it is that the Tulip trade is greatly improving. Especially the rarer and newer varieties are much in request, and single bulbs are sold among growers for 2s. and 2s. 6d. I wili write down a few of the names for your guidance, should you care to try Tulips in your garden. The Queen of Holland is of a rose tint, touched with silver, a charming flower; Pottebakker is true scarlet, and the largest Tulip grown. Jenny and Pink Beauty are rich pink, Joost Van der Vondel pure white, and Golden Queen is the largest of the yellow Tulips. Then there are all the early double Tulips in infinite varieties. They are grown in the garden just like Hyacinths, and I need not tell you what the effect is of a fine Tulip bed or a clump of Tulips among shrubberry in April and May. These flowers require no recommendation."

"But you must have Hyacinths indoors, in glasses and pots. You want to watch them day by day as they unfold. It is an interesting process. First, then, about those in glasses. If you want them to flower about Christmas put them in at once; the rest later on. Fill a Hyacinth glass with pure pond or rain water, and put a few grains of salt in each glass to keep the water clear. Let the bulb just touch the water with its lower surface. Put the glasses away in a cool dark place for four or five weeks, by which time the roots have grown strong. Then bring them into the light in a living room, but do not let them stand over the fire or in a dry atmosphere. Add a little water as the first supply evaporates, otherwise don't touch the bulb; and if the water becomes muddy it must be changed. This is all; for the rest the bulb takes care of itself."

takes care of itself."

"To grow Hyacinths, or indeed any other bulbous plants for spring flowers in pots, you want good light soil; loam, with a liberal mixture of old cow manure, a little leaf mould and sand, is best. Provide drainage, and keep worms out. Then fill with soil, putting the bulb in the centre, so as to allow the point to be on a level with the surface. Press the soil firmly down, water well, and cover the pots in an out-of-the-way corner of the garden for a few weeks. Then, when the roots are well advanced, put the plants in a greenhouse or a room in the house where they are to flower. Place them near the light, keep well watered, and by February and March you will have Hyacinths in perfection."—("Westminster Gazette.")

FRUIT FORCING.

Vines.—Late Grapes.—Although the principal winter supply consists of what are termed thick-skinned varieties, no one knowing anything of the quality of Grapes will take to them so long as Black Hamburghs, Madresfield Court, Foster's Seedling, and Muscat of Alexandria are forthcoming. It is difficult, however, to keep these thinskinned Grapes in good condition. Black Hamburgh and Madresfield Court become red when exposed to strong light or sun after being ripe, while Foster's Seedling and Muscat of Alexandria acquire an undesirable brown colour by hanging for a considerable time after they are ripe. This is due to the changes effected in the berries by the atmospheric conditions. The thin-skinned Grapes must be kept in a well ventilated atmosphere to protect them from shrivelling by too little or of damping by too much moisture. They can be kept on the Vines until the new year, or later where the houses are constructed upon sound principles for the insuring of a regular temperature and uniformity of moisture. But where the houses are not drip-proof or the panes of glass have large and bad fitting laps so that the water hangs in them, and is driven in by wind over the bunches of Grapes, causing them to spot and decay, it is evident that the bottling system must be practised if the thin-skinned Grapes are to be kept sound till Christmas or later.

Of late or thick-skinned Grapes Lady Downe's is the best keeper, retaining its colour better than any other, unless it be Alnwick Seedling, which certainly is an excellent vinous Grape, but it is neither so free bearing or of such high quality as Lady Downe's. Mrs. Pince Grape will shrivel in an atmosphere where Lady Downe's keeps plump and the berries turn an undesirable red colour. Its quality is unimpeachable even when red and shrivelled, and both Lady Downe's and Mrs. Pince have quality which no other late Grapes possess in the remotest degree. Alicante is free from the disagreeable earthy taste of such varieties as Gros Maroc and Gros Colman, and invariably sets freely, finishes well, and is an excellent keeper. It, however, has not the quality of West's St. Peter's, which is not so imposing in bunch or berry, but the colour and bloom amply compensates for any lack of size. It is one of the best late Grapes for quality, and keeping up to February. Gros Guillaume is the most imposing in bunch of black Grapes, and the berries are small, inferior in size to those of Gros Colman, while the quality is better. It requires time in ripening, needing to be started early in spring, and must not be overcropped, or the berries will not colour nor even ripen. Gros Colman is the most magnificent in appearance of all black Grapes. In bunches of 4 lbs. weight and berries 4 inches or more in circumference, well finished in every respect, it is

really enough to tempt anyone to purchase it if they can for its superb appearance. Well ripened, and allowed time to mature before cutting, it loses the earthy taste so characteristic of this variety when fresh ripe or coloured. It requires to be started early, so as to finish thoroughly by September.

Of late white Grapes Treboiano is unquestionably the best when well ripened. It is certainly coarse in flesh, yet firm, crisp, sweet, and requires thorough ripening. Syrian also needs plenty of time and heat, artificial fertilisation, well thinning, and ripening up to an amber colour, then its large bunches are very effective, and the flavour not bad. Calabrian Raisin has fine bunches, berries of good size when well thinned, and the Grapes are sweet when well ripened. With the above or other varieties a supply of Grapes may be had from November to May inclusive at a great advantage to the Vines and to the grower from an economic point of view; but it is still necessary to start Vines of the thin-skinned varieties early, in order to meet the demand for such fruit. It is not desirable, however, to start permanently planted-out Vines in the autumn or early winter, as this is a great strain upon them through their having to make their growth and ripen their crops under disadvantageous circumstances, which soon wears them out.

advantageous circumstances, which soon wears them out.

Earliest Vines in Pots.—Where thin-skinned Grapes are required in late March and April, the Vines must now be started, or placed in position so that forcing in earnest may commence with November. Some persons have a prejudice to Vines in pots, but they produce fruit little inferior in size of bunch or berry to that borne by early forced, planted-out Vines, and it is generally better in quality through the conditions of cultivation being more favourable. Especially is this the case where there is the convenience of affording bottom heat. Success is then certain, the canes being sufficiently strong, thoroughly ripened, duly rested, and of suitable varieties. Of sweet Grapes none excel Black Hamburgh and Foster's Seedling, of Musk Grapes Madresfield Court and White Frontignan. The materials for affording bottom heat—that is, tree leaves and stable litter, should be in due course of preparation. To begin with, the heat about the pots should not exceed 65°, augmenting it by bringing up the fermenting materials to the level of the pots, so as to raise it to 70° or 75° when the Vines are in leaf. Only supply enough water to keep the soil moist in the early stages, as excess of water tends to render the soil sodden and sour, hindering root action. Vines in pots not intended for early forcing should be placed under cover, an open shed with a north aspect being suitable, and the pots protected with hay or straw.

Renovating Vine Borders .- Where the Vines are unsatisfactory no time should be lost as soon as the leaves have effected their functions to the extent of perfecting the buds and wood, and whilst they are still upon the Vine, in removing the soil down to the roots and picking it from amongst them, so as to displace as much of it as possible with fresh. Where the border is very unsatisfactory, and the roots few and deep, it will be necessary to remove all the soil and renew the whole border, commencing with the drainage, which should be clear 1 foot thick, having a layer of fine material at the top, nothing answering better than old mortar rubbish, a 3-inch thickness over 9 inches of brickbats or rubble. The drainage must have a 3-inch tile drain under, with proper fall and outlet, to carry off superfluous water. Two feet depth of soil is ample. Turfy loam, containing a good per-centage of small stones and grit, is unquestionably the best. It should be of medium texture, that overlying clay being better than that overlying sand; but red sandstone formations give most lasting results. Strong loam interspersed with flints or calcareous gravel is excellent. To ten cartloads of turi, cut about 3 inches thick, add two cartloads of old mortar rubbish, one each of horse droppings and wood ashes, and 4 cwts. of crushed ½ to 1-inch bones, mixing well together. The roots should be laid out evenly in the top foot, encouraging those from the collar by laying any that proceed therefrom only just beneath the surface. The whole should be made firm, and the compost be moderately dry. the roots are inside and outside, one part may be done one year, and the other the next, without any danger of loss of crop, by preserving all the roots possible, and keeping them as much as practicable from the drying influences of the atmosphere whilst the work is in progress. Mulch the surface with a little short, rather fresh, manure, preferably horse droppings; outside borders may be covered with sufficient leaves and a little litter over them so as to exclude frost. The work should not be delayed beyond change of colour in the foliage of the Vines for falling. Any Grapes then remaining may be cut and bottled.

Melons.—The season as regards manure-heated pits and frames is at an end. Any fruit yet remaining may be cut, they being full grown, and placed on shelves in a warm airy house. The latest plants in houses will require a night temperature of 65° to 70°, and 70° to 75° artificially, advancing to 85° with sun heat. Sprinkle the paths and other available surface about 8 A.M. and 3 P.M. until the fruit is full sized, when a drier atmosphere will be more suitable. Cut out all superfluous growth or laterals, well thinning the old foliage, so that the fruit may have the full benefit of the autumn sun. Do not allow flagging through want of water, but keep the foliage healthy until the fruit is ripe, as the quality is in proportion to the health of the plants. Maintain a rather high, well ventilated and dry atmosphere when the fruit is ripening.

PLANT HOUSES.

Palms.—All these plants should be carefully examine, and if thrips exist upon them they ought to be eradicated at once. If not destroyed now they will spread rapidly and do much damage to the

foliage. Do not allow the atmosphere to become dry, or else these pests will spread rapidly, and apply sufficient water at the roots to keep the soil moist. The temperature for the majority of these plants may be Seedlings that are large enough can be placed singly into These should be kept in brisk heat and the pots plunged about 60°. small pots. where practicable amongst cocoa-nut fibre refuse where they can enjoy gentle bottom heat. This will keep the plants steadily moving and prevent having to water them too frequently.

Begonias.—Those that have been prepared for autumn and winter flowering and have been in a cold frame up to the present time should be placed where they will enjoy a night temperature of 55°. B. Knowsleyana will soon come into flower and be useful for the conservatory, while B. Ingrami will continue to blossom for a long time. Young plants of this variety that are just rooted should be pinched and placed into 2-inch pots. These when repotted early in the spring will be useful for various forms of decoration. The varieties of B. nitida may be placed into larger pots, and if kept steadily moving will flower freely during the early spring months. B. semperflorens and its varieties will, if given a temperature of 50°, come quickly into flower and continue to grow and yield their large useful trusses for several months. Such kinds as Weltoniensis that are past their best should have less water supplied to them, and then be stored away in a cool dry place for the winter

Amaryllis.—Where these are properly grown, and have been fully exposed to the sun, the bulbs should be well ripened. The pots containing the bulbs may now be stored under the stage of any cool airy Plants that are not thoroughly matured should have every ray of sunshine and a free circulation of air. Do not withhold water from them too suddenly, for nothing is gained by unduly hurrying them to rest. They must, if they are to flower well, be properly matured, and given every chance to store up food in their bulbs before they are completely dried.

Epiphyllums.—Where these have been well ripened by exposure to the sun and have enjoyed free ventilation they would soon come into flower if placed in a temperature of 50°. These plants are particularly effective when arranged so as to stand out of a groundwork of Adiantum cuneatum. Less water will be needed at their roots, but by no means keep them dust dry, such treatment will soon ruin them.

Eucharis amazonica.—It is a mistake to allow many plants of this to come into flower at one time, because very frequently some of the blooms are wasted. Those plants that have finished their growth should be removed from the stove to a temperature of 50°. Cold draughts should be avoided, and the plants must receive less water at their roots; but on no account allow them to suffer by an insufficient They will rest under these conditions, and in a short time, if again introduced into brisk heat, will push up their flower spikes freely. A long succession can be maintained by resting a few plants at a time.

Pancratiums.—Give these plants less water at their roots, but do not unduly dry them so that they lose their foliage. If placed in a temperature of 55° they will be safe until it is necessary to start them again into growth during the early months of the year. When kept in again into growth during the early months of the year. When kept in too much heat during the winter the plants are very liable to the attacks of thrips.

Anthurium Schertzerianum.—Plants that have matured their growth and are required to flower early may be removed to a house in which a temperature of 50° is maintained. If cold draughts are avoided and less water given they will rest perfectly under these conditions, and flower profusely when replaced in a higher temperature.

APIARIAN NOTES.

PRACTICAL HINTS FOR BEGINNERS.

(Continued from page 334.)

BEES sometimes complete swarming in little more than a minute from the commencement, and at others are so tardy that ten to fifteen minutes may be occupied, so few bees leaving that a tyro might not suspect they were going to swarm. Sometimes, too, they cluster and settle in five minutes from the time they commenced to leave the hive, while at others they will fly about for hours, often gathering in many small clusters. If the weather is fine, they will in the latter case come all right, but should it rain there is a great risk of most of the bees being destroyed. A few oilcloths at hand to cover the largest clusters (which the queen, if not present, soon joins) often saves a swarm. The beginner must also learn that joins) often saves a swarm. The beginner must also learn that many swarms leave without the queen accompanying them. In that case they sometimes join other hives, or return to the parent one. The appearances of bees on these occasions must be learned by experience. To describe the matter properly on paper is scarcely possible.

When bees gather on a low bough or bush they may be at once shaken into the swarm catcher, or if they are on the ground it may be placed over them, when in a short time they will ascend into it, accelerated by a free use of a carbolised feather tied to the end of a long rod. These carbolised feathers will dislodge bees from thickets, crevices, roofs, and other inaccessible places; in fact, by judicious management they may be almost made to swarm in the very place wanted. Bees sometimes settle on trees at a great height, and on branches that cannot be cut. Wherever the swarm catcher can be applied, from the ground or by the aid of ladders, it ought to be adjusted to the proper height, held over or under the bees as is most suitable. In the latter case they must be shaken into it by a helper or by the aid of a shaker, a hook fastened to a pole or wire. In the former instance the carbolised feather hastens the ascent of the bees, and when all or most of them are in and covered with a cloth the hive may be lowered to the ground. On reaching the ground the hive is at once inverted, and after standing a few seconds to allow the bees time to settle, raised a little to allow the flying bees to enter.

When bees settle in inaccessible places on trees, whether the branches may be cut or not, the hiver may be applied successfully by being provided with cords, a piece of hooping or other material having a hook on one end, and provision at different heights for fastening a pulley, which is suspended so that it comes under or over where the bee-keeper wants it. For example, if a swarm is settled a long way out from our reach, the hook with the pulley and cord is hung directly where it is most convenient, the swarmcatcher is then drawn up right under or over the bees, and is held or placed in proper position by the aid of a forked and pointed hook, when the bees may be either shaken or driven into the swarm catcher. When the branch may be cut with the last-named hook, push the cord forward with it till the loop hangs free. Then take hold of the loop with it, pull it towards you, pass the end of the cord through the loop, and draw tight. Now pass the other end of the cord through the suspended pulley and hang it in position, when the bee-keeper may venture from his safe standing near the bole of the tree to the point where the branch has to be cut, after which, by the aid of the hooks, the bees may be guided to an opening where they can be lowered to the ground with safety. The above plan is a good one, and is far more easily performed than it appears to be on paper.

On page 344 a slight omission occurs in the last paragraph. It should read, "As a substitute for the safety cages those sent from Austria cannot be surpassed," and then follow on as printed.—

A LANARKSHIRE BEE-KEEPER.

(To be continued.)

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Insects on Vine (G. G. K.).—The insect is a species of Tetrix, closely allied to the grasshopper proper, the section Gryllina, and is an undescribed (if British) species. It no doubt lives on the leaves of the trees it is found on, for it belongs to the same family as the locusts; but it may only be on the Vine now tor the purpose of depositing its eggs in the crevices of the bark. Whether it is injurious to the Vine or not we are unable to say. This, however, can easily be ascertained by careful observation. If you find such to be the case we should be obliged by specimens of the leaves eaten, also fresh ones of the insect

Flowering Plants for Growing Under Beech Trees (J. C.).

—We have had very little success with Winter Aconite, Snowdrops, Daffodils, and similar bulbous plants that do fairly well under trees, for the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the Beech trees form as complete a returned and the roots of the r the roots of the Beech trees form so complete a network and run so near the surface, combined with the dense foliage, as to prevent the growth of

plants beneath. It is even very difficult to keep the ground covered with grass, and still more so to find thriving Ivy on the trunks of Beech trees. The Clematis belongs to the Jackmanni type. It is not a species, but a florist's variety, and can only be named by comparison in a large trade collection of the flowers.

Poetry (*Planta*).—We meant exactly what we said in our reply, and if you cannot understand it we cannot help that. We fail to observe your name and address, even in the letter written after our special intimation. We exist to give information on gardening subjects, and not for hunting up books and authors of certain "lines" that are sent to us from time to time anonymously.

Mina lobata (A. F. Grace).—The flower sent is Mina lobata. This plant was originally introduced from Mexico in 1841, but it either died out or for a long period was so exceedingly scarce as to be practically unknown to the majority of cultivators. A few years since, however, it was re-introduced, and has since become generally grown. It is a half-hardy annual plant, and therefore dies on the approach of frost. Propagation is effected by sowing seeds in February or March, placing them in a pot or pan filled with light sandy soil, and put in a warm greenhouse, stove, or frame on a hotbed. When the young seedlings are about 3 inches high transfer them singly to small pots and grow in an ordinary greenhouse until the first week in June, when plant them out against a south wall as you did last spring.

Galls on Oak Twigs (W. H.).—The fresh growths of young Oak trees are frequently tipped with galls (so called) of a gall midge (Cecidomyia querci), the female laying her eggs in the terminal bud of a twig, the larvæ hatch, and the result of their operations is the formation of a gall, which bears a strong resemblance to a cone in its form and in the overlapping of the leaves of which it is composed. Among the leaves of the cone the larvæ of the midge may be found. The galls are usually solitary, though two, or even three, may be found side by side at the tips of the twigs, the terminal buds of which they destroy. There were no larvæ in the cone, therefore we are unable to say positively whether the cone was due to the gall midge or not, but it differs from the Artichoke gall in having a solid centre. The Artichoke gall, formed by Aphilothrix gemmæ, very much resembles a diminutive Globe Artichoke, and is about 1 inch long, formed of scales, with a central chamber like a small acorn. This is a true gall, but we failed to find the chamber mentioned, therefore we name the two forms to enable you to arrive at a satisfactory conclusion by the examination of other specimens.

Exuberant Young Fruit Trees (Inquirer).—The trenching and heavy manuring two years ago is no doubt the cause of the trees growprune the Apple and Pear trees more freely than the Cherry and the Plum. We should not shorten the roots of arms of the cherry and the two-thirds the distance from the stem all round that the branches extend, cutting off some of the thickest roots there, while all may be detached by taking out a trench at the point the branches cover. It is probable that the trees have straight down roots; these must be sought for and severed at 15 to 18 inches beneath the surface. The trees also should have the heads thinned, leaving the main branches near the stem so that a man can get his body between them after they have grown out 3 or 4 feet, and nowhere nearer than a foot apart, cutting any side growths, but not spurs, to about an inch of their base. pruning should precede or immediately follow the root-pruning. be useless, however, doing any of these things unless the ground is kept firm and not more than hoed or pointed over as far as the branches extend, nor ought the ground to be cropped with vegetables to a similar distance.

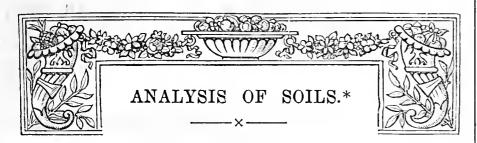

Lycium europæum (P. W.).—This is the name of the plant of which you send a fruiting spray. The hedge, which you say is full of it, must be highly ornamental. The glistening scarlet fruits, three-quarters of an inch long, and three eighths of an inch thick, are produced in pairs almost close together all along the spray. The shrub is a native of the South of Europe, but appears to have become naturalised in some parts of this country. Loudon in his "Encyclopædia of Trees and Shrubs" describes it as "valuable for covering naked walls, as it grows with extreme rapidity, and flowers and fruits freely in almost any soil or situation. Established plants in good soil will make shoots 10 or 12 feet in length in one season, and the plant when trained against a house or high wall will reach the height of 30 or 40 feet, as may be seen in some courts in Paris. Trained to a strong iron rod to the height of 20 or 30 feet, and then allowed to spread over an umbrella head, it would make a splendid bower. Its shoots would hang down to the ground and form a complete screen on every side, ornamented from top to bottom with ripe fruit, which is bright scarlet or yellow, and very showy; with unripe fruit, which is of a lurid purple; or with blossoms, which are purple and white."

Cucumber Plant Diseased (T. L.).—The portion of stem and root is badly infested with root-knot eelworm (Anguillula radicola, or Heterodera radicicola of Müller). It was first discovered by the late Rev. M. J. Berkeley in this country, and was figured by Mr. W. G. Smith in the Journal of Horticulture of July 26th, 1877; but it was known to gardeners as the "sudden collapse" disease many years previously, and was treated of by the late Mr. R. Fish from a practical point of view.

The eelworms in your specimen are mainly confined to the root portion —deformities and nodules, and are quite beyond calculation in number. A few only were found in the stem, and those in the portion which had been buried in the soil. The eelworms are in all stages, from the egg or cyst onwards, and are remarkably fine specimens. They are able to subsist on decaying tissues, and perhaps find enough decomposing matter in the soil to live upon and even multiply in after the destruction of the This is mentioned because the eelworms are said to live host plants. several years in a passive state, and become resuscitated on the crop they thrive upon being again grown on the same ground. We find, however, that the eelworms soon collapse on a dry glass slide, even whilst under microscopic examination, and we cannot accept the dictum that they have the power of resuscitation. Besides the eelworms we found an innumerable host of other bodies in the stem portion. They are bacterial, and in a fully active state; but what part they play in the disease we are unable to say on account of the decayed condition of the tissues of the plant. There is no remedy for either the eelworms or the bacteria known at the present time, though there are many substances which will kill both, but they are fatal to the hosts as well as The only thing we can suggest is to burn every part of the plants, clear out the soil and fermenting material, if any, and commence again with fresh soil and plants. If you use turfy loam char it slightly over a wood fire before use, or in other words, heat the sods so that the outer surface while they are on the fire is hotter than the hand The eelworms have been introduced with the soil, the can bear. manure, or water, generally the two first.

Diseased and Scabbed Potato (J. J.).—The tuber is in a very deformed, diseased condition, a veritable hotbed of disease-producing micro-organisms. The Potato proper is infested by the mycelium of the Potato fungus (Phytopthora infestans), the spiral threads enclosing the resting spores being well pronounced, and also the threads or mycelium of Fusisporium Solani, and is the early condition, Periola tomentosa, from which the Fusisporium at length arises, for there is neither the outgrowths (spores) nor resting spores. The latter fungus F. (Hypomyces) Solani is considered to be the cause of "dry rot" in Potatoes. other parts of the tuber are badly scabbed, and some parts in a state of decay bordering on putrefaction and swarm with Bacterium navicula and Baccillus amylobactor, whilst the exciting cause of the worts is due to the mycelium of the scab fungus (Tubercinia scabies), and the "fruits" are distinctly visible (under the microscope) emerging through the stratum above the mycelium. There is also the spawn of some fungus outside the scabbed portion of the tuber, visible to the naked eye, but we failed to discover with a powerful lens the insects you found with a pocket lens, yet we have no doubt of your having seen them. They are probably Lipeira femetaria. It is very common and may be found in damp earth throughout the year, feeding upon Potatoes, Carrots, or other roots, especially where distorted or scabbed. ceding is not all, for the tuber had been eaten by some grub, and, strange as it may seem, that part had not been molested by any of the microorganisms. The gnawing had manifestly been done by the grubs known as "leather jackets" or larvæ of Tipula oleracea or daddy longlegs. You ask what we recommend to prevent a recurrence of the trouble next year. First of all a change of ground for the Potatoes, or if that is inconvenient dress the land now with fresh gas lime, using 28 lbs. per rod (30 $\frac{1}{4}$ square yards), spread it evenly on the surface and leaving it there for a month or six weeks, then you may manure the ground if necessary, dig and throw it up roughly for the winter. In March, or earlier if the ground is in good working order, level it with a fork, applying a dressing of quicklime at the rate of a peck per rod, and point in lightly. At the time of planting use the following chemical manure: Mineral superphosphate, 2 cwt.; kainit, 1 cwt.; sulphate of iron, ½ cwt.; mixed, sprinkling it all over the ground at the rate of $2\frac{1}{2}$ lbs. per rod, before covering up the sets. If the ground is not manured in autumn, add 1 cwt. of nitrate of soda powdered to the above mixture, and employ $3\frac{1}{4}$ lbs. per rod of the full mixture. A change of seed is imperative.

Chemical Manures (F. J.).—What is the use of our advising you if you do not test the advice, but instead suggest some other formula as better than the good and simple one we recommended of ingredients easily procurable? If you wish to have a mixture adapted with scientific exactitude to your soil you must send a sample of the soil to an agricultural chemist, and ask him for a quantitative analysis. He will then tell you, as we could, the proportions of lacking ingredients to add for rendering the soil fertile. This you will find a costly process, and in our opinion it would be of no practical use in your case; still there are persons who like to indulge in the luxury of scientific investigation, and are willing to pay for it, and in this reference we have no objection to others doing what we should not do ourselves. If you like to use costly potassic nitrate, or in other words nitrate of potash, or, as you request it in "plain English," saltpetre, as a manure, you can substitute it for kainit; but as you seem particular about "plain English," it will save you and ourselves some trouble if you will try and make your questions plain and your object comprehensible. You did not mention the subject of fruit trees cankering in your former letter, but simply asked for a general manure for "crops, fruit trees, &c." How could we know the "&c." meant canker? The convenient symbol may mean anything or nothing, and is far too glibly used. The most careful men and best writers never use it, and you do not often see it in the letterpress of the Journal of Horticulture. It appears you had the canker of fruit trees in your mind when writing, and signified the same by an "&c." We gave an answer to the question that you really

REMEMBER being almost bewildered by a sentence in one of Darwin's books. "Few plants," said he, "grow on the soil or in the locality best suited for their requirements." This seemed for the moment contradictory to his whole hypothesis, but carefully thought out it is only a seeming paradox, not a real one. Its parallel in human sociology is, "Few men live and work under circumstances they are best adapted for." We should all be much better than we are if our environment were better. We can all of us imagine a set of circumstances under which our natural virtues would flourish exceedingly, and our no less natural vices diminish. We, like the plants Darwin spoke of, grow and flourish as we best can, where we are allowed to do so. We are where we have drifted to by the exigencies of the struggle for existence. Plants grow where they can. Heather grows on the moors, not because it could not grow on better soil, but because, on better soil, plants that could not grow on the moors can grow there, and do so, choking the Heather at its starting point. I do not know if Heather is the best illustration I could have given, but it will serve. What do you think Heather would develop into if tended and nursed under the circumstances which, if we knew them, were best fitted to it? Rhododendrons grow in the Himalayan districts into huge trees—lurid masses of blazing glory, as large as the Major Oak at Clumber; and who shall say our humble Heather might not develop into beauty as great? Mignonette, an annual plant, can, by care and culture, be made to grow a bark, and be developed into a tree strong enough to brave an English winter in the open. Nay, of what can be done we know nothing. Our wildest dreams, of necessity, must fall far short of realising the fathomless stores of energy and inherent power of development in organic life. The great chemist Nature had behind her the infinite power of infinite wisdom, and that which these thought fit to start cannot but be worthy of the starter; to say otherwise is to make a statement not logically thinkable. With infinite potentiality, then, in all organic life there is ever-abundant room for greater and still greater amplification of result. Every step upwards points with increasing certitude, to another still higher, the way to which lies through patient study of Nature. All study of Nature is ennobling, lifting our sordid souls from the grovelling selfishness of life as it is to the altitude of life as it should be.

I know nothing of Chrysanthemums. I know that "chrysos" is the Greek word for golden, and "anthemon" is the Greek word for flower, so I presume the original flower was yellow, but I think they are now all the colours of the rainbow, and might very well be rechristened "Irisanthemum." This is all I do know about them, and am not at all sure that I know this much with certainty. The Chinese get Roses as large as a dinner plate by resolutely nipping off every bud but one, and I know the Japanese can get a whole forest of trees in full leaf and form on the same dinner plate by as resolutely pinching off every tendril as fast as it forms, and I do not know any reason why you should not grow a Chrysanthemum as large as an umbrella, or as small as a Forget-me-not if you wish to do so.

But what is soil composed of? This is a question oftener and much easier asked than answered. It is broken down, storm rent,

No. 696.—Vol. XXVII., THIRD SERIES.

rock, and broken up clays, the débris of sandstone and limestone, the sediment of rivers, the forces of flood and fire, earthquake, and thunderstorm, the wear and tear of traffic, meteoric showers, the dust of broken up worlds wandering in space, all contribute their quota to the soil. Newspaper correspondents tried to make merry over the non-arrival of a comet not long ago. It does not strike these would-be humourists that the comet is very largely composed of dust, and if one struck us we should only consider it an unusually dusty day. Whence comes the sand and dust that buries cities such as Carthage, Troy, Babylon, and Nineveh, Palenque, and Copan? Years ago Russia, with her usual honesty, bought territory from the Kirghiz chiefs at a price the Russians fixed, and collected "voluntary" signatures by the playful flourishing of rifle and sword, and allowed the sellers to build Russian forts on the territory so sold, finding the bricks free of cost to the buyers. A bargain you will admit; a trifle one-sided, perhaps, but distinctly sweet to the Russian palate, if not to the Kirghiz taste, and you know it is difficult to please both sides when a good bargain is made. How was it these perspiring Kirghiz brought better bricks than they or the Russians knew how to make? The Russians, very scientific and inquiring people, wanted to know, and the unscientific Kirghiz did not want to tell, but the Russians know several sciences, one of them relating to the conversion of silence into eloquence by the application of stout sticks to the soles of tender feet. By these means they got into conversation with their brickmakers, and discovered that the particularly good bricks had been found in the soil, and were the top of a cupola. Well now cupolas mean cities not very far away, and there are no doubt buried cities in abundance in Siberia. The Kirghiz steppes are full of tombs, evidently tombs of chiefs buried in their war trappings, and their trinkets of gold and silver beside them, and thousands of such tombs mean many cities; they are not on the surface, and are therefore probably beneath it, as the cupola was, and the blowing about of dust from place to place does not quite account for buried cities. There must be continuous showers of meteoric dust, which our earth receives in her rush through space.

We must then consider soil partly, and in large part the ruins of former worlds. Liebig, the father of agricultural science, as he is very rightly named, makes much of humus and humic acid in the soil, but these are but the relics of decaying vegetation, and their fermentations. To the kindly embrace of Mother Earth go back all vegetable and all animal life; and it may be taken as an axiom, that anything that has come out of the soil acts the part of good manure on being put back into it. Cabbage or cow, mast or man, duckweed or dude all alike spring from the soil, and returned thither revivify and renew the face of the earth. Nature is restless, incessant change is the one persistent law of all life. A generation rises, flourishes and decays, and in its decay nourishes the following generation. Herbert Spencer thinks Nature seeks stable equilibrium, and it may be so. It is nothing paradoxical to say she seeks it by non-stability, and if she seeks at all it can only be by non-stability. Rest is brought about by unrest, peace is sought by means of war. It is inevitable that if Nature is seeking aught, it is perfection. As the working power of All Good, can she seek aught else? As the agent of All Wise, can she seek anything? Granting that she seeks perfection, can perfection be reached? Our mental fingers fail to grasp the idea of a time when nothing can be improved. Should that time arrive, it will be the Nirvana of Buddhism. Mental effort must then cease, and a dull consciousness be all and in all to all the sons of men. But we are getting away from the soil to the cloud, let us get back to the earth; but we shall land in the clouds again and again, for all the paths human thought can travel lead thitherwards, and lose themselves and us also in the impenetrable folds of Nescience.

To analyse soil is at present impracticable. We can analyse flowers, tubers, plants and roots, but to do so we must first get rid of the water. Water plays a strangely important rôle in this

^{*} Read by MR. W: PICKARD at Sheffield. (Concluded from page 348.)

planet of ours. An 11 stone man is 8 stones water; a Chrysanthemum is rather more watery still, a Potato is 75 per cent. water, a Turnip is nearer 90 per cent. Is it not surprising what water can do—whether with whiskey or without it? I think it was Dr. Frankland who took the trouble to analyse a jelly fish in an oven. It weighed 6 lbs. to begin with, and when all the water was gone there was just 16 grains of something left. This water is not usually considered a sensient thing, but it gets very near it. That 16 grains of something, phosphorus and sulphur and carbon and some other elements, had managed, somehow, to make more than half a gallon of water sensient for the time being. A tree is from 30 to 40 per cent. water at full growth. When you get a 10 oz. Chrysanthemum you will find nearly 9 ozs. of it water.

When you have reduced your plant to ash you have dispersed its water; some carbonic acid, a little sulphur has perhaps been sublimed, but these are of no importance to the analyst. The future plant can get those items from the atmosphere. What is left is the potash, soda, iron, magnesia, and lime, phosphates, sulphates, and nitrates, and it is these you have to add as manure in the same proportions as you find them in the ash. If the ash contains 9 parts potash to 3 parts soda you gain nothing (but the loss of the soda) by adding more than 3 parts. The coming plant cannot take up more than 3 parts of soda to every 9 parts of potash it can find. If you forget to put the 9 parts of potash in, and there happens to be none in the soil, you cannot get the plant at all, no more than you can build without building materials. It is the same with all the other constituents. They will make a plant in the proportion specified, and no other. If suppose of seven of the constituents you give enough for a thousand blooms, and of the eighth only enough for one, you will only get one. The other constituents are idle, waiting for their absent comrade; they can do nothing without him. It is not at all surprising; it cannot be otherwise.

It would be useless to tell you how to ascertain what amount of each chemical there is in the ash. It would take hours to do that, and it would not interest you. If you wish to learn how to do it obtain some text book on chemistry, and plod away at it till you master the subject. There is no royal road to chemistry. Hard study and long practice is the only way, and you will find disappointment thicker than you ever found Blackberries. The facility with which you can make a mistake is surprising.

On the suitability of a soil for Chrysanthemums I had better not enter. If you do not know more than I do on that subject you will find I should say breaking stones as an industry considerably the better of the two occupations. As a manure for Chrysanthemums I should say phosphate of soda and saltpetre (with a little sulphate of iron in it if you want colour) is as useful as anything, but I am rather inclined to think horse manure is good.

In conclusion let me say this. If the love of flowers and the love of Nature in her beauty be not worthy of man, then flowers were not worthy of creation. If the gratification of the human eye, on which Nature has expended so much ingenuity and furnishes with such complex and marvellous machinery for the detection of beauty be not thought worthy of study, then Nature herself has been and still is working on the wrong lines.

If our sense of the beautiful is not to be gratified why have we such a sense within us? The lover of flowers is usually a kindly man, a man with a good, sound, reasonable sort of a soul in him, he cannot well be wholly base and vile. In his leisure hours his plot of land would not entice him away from plotting evil against his fellows. Amid his flowers, emblems of innocence and purity, he cannot be altogether unmindful and unthoughtful of the lessons and sermons they hourly preach. They must appeal to some cognate, moral beauty of character, concealed somewhere within him. The orderly and symmetrical development of bud and petal must convey some lesson to heart and brain, and in some sense sways his steps through life. Love of Nature argues at least one soft and tender spot in the human heart, the sordid and

mean have not absorbed all its faculties, or closed mental eyes to all that is sweet and pure. His thoughts must, at times, rise above and soar away from the dissonant clash of contending interest, and now and then, at the least, lift him from the contemplation of his flowers to that of the Great Flower Grower, the Original Gardener, the source and fountain of their being, and of ours and our respective places and duties in the drama of life, and to the still greater question, as to whether we fill our part half so well as they fill theirs.

THE TREATMENT OF OVERCROPPED FRUIT TREES.

IF people would follow the commendable practice of pruning every year, be it ever so little, we should not see orchard and garden trees, as we do this year, subjected to the bearing of weights in excess of their strength and crushed under a preposterous mass of fruit, which by its very superabundance loses both in appearance and in quality. The trees thus maltreated cannot fail to exhibit symptoms of it for many a day in their health as well as in the matter of their product. There is, however, an antidote for every ill, a recuperative for all exhaustion. On this occasion, therefore, it becomes us to resolve and act promptly. We accordingly prescribe a combined treatment con-

sisting of pruning, dressing, and feeding.

PRUNING.—In September or October, before the fall of the leaf, administer a severe but judicious pruning to the branches and boughs which have borne an excessive amount of fruit. If the pruning is too short it will have the effect of dangerously mutilating the old wood and depriving the head of the tree of the sap furnished by the last shoots. If, on the contrary, it is too long, it will be inefficacious. The happy medium can be estimated according to the age and vigour of the tree, a young and vigorous tree being able to bear more drastic treatment, though we may remark that it is not common to meet with an excess of production under such circumstances. For the rejuvenating or renewing of the crown it will be sufficient to preserve in the frame-work of the tree its pyramidal, spherical, or diffused aspect following its first direction should this be considered desirable. The main branches should be taken off with the saw, pared smooth, trimmed, and daubed with clay. The pruning-knife or caterpillar-cleaner will do to clear off the flower-bearing shoots, spurs, and other elements of fructification. Here the more crowded ramifications should be relieved with the pruning-knife; elsewhere they should be shortened upon a live bud, while none need be lopped off unless they be completely worthless. It would be a wise precaution also to look over the shoots of the year which might spring up from the midst of the general lassitude, pruning the longer but leaving untouched those shorter ones which are likely to be the first to vegetate.

The Apricot, the Plum, and the Pear are the fruit trees which present the most striking examples of over-production. In the case of the Cherry the traces are not so marked. Its fruit, though plentiful, was not so excessive as to seriously exhaust the tree, and the two or three months of summer remaining sufficed for its recuperation before the winter time. The Apricot easily develops buds on the old wood, but this is no reason for mutilating the large branches too low down, as the new shoots would appear in an irregular manner, and might be killed in their first season by gum

or by heat.

This pruning of the principal organs of the head ought to be done above a certain number of wood or fruit branches. former of these should be shortened on the shoots, and the latter on the living bud. It is almost only in the region of Southern France that we can safely allow a more energetic yield of the Apricot, the Almond, and the Peach, in the open air. We are speaking especially of the out-of-doors tree trained as standard, half-standard, and dwarf. The Plum will keep the most of its fruiting shoots, whether pruned or unpruned; but it should not be forgotten in diminishing and reducing the substance of its framework in length that the latent buds are less numerous upon this sort The Plum presents an advantage which we also find in the Pear and the Apple, namely, the grafting of the main branches which may have been injured by accident. For the Plum we advise cleft grafting in autumn before the stagnation of the sap. will give an opportunity of modifying the variety of the tree by the grafting of a more agreeable sort (of scion). If the graft should fail it can be repeated in spring time either in the cleft or at the crown. The pruning of the original branch work will then be deferred until the rising of the sap, and practised gradually as the grafts develop. Pippin fruits, such as Apples and Pears, should be severely pruned, always in the autumn.

DRESSING.—This consists in cleaning with a brush and washing

the aërial parts of the tree. Furnished with a rough brush or a scraper rub off the moss, lichen, scales, and old bark which impede the regular action of the organs, and serve as a shelter for insects; give also a good cleaning to all cracks, cavities, and canker spots. The stem and branchage being thus refreshed, a general bathing should complete the hygienic process. The whole should then receive a coating of lime mixed with sulphate of iron and a slight

admixture of other and clay.

FEEDING.—In addition to the above we would recommend the following measures: -Clear away the earth around the tree to a distance of about a yard and a half, and excavate the soil to a sufficient depth, so as to expose the chief roots without injuring Fill in the trench with a compost taken from the kitchen garden or field, mixing with it decomposed night soil, river sand, sweepings, leaves, scraps, rags, pond or stable slops, and other animal and vegetable débris well reduced. Lastly, water copiously with liquid manure. This triple operation should be performed at one time—before the end of winter. When the sap has begun to rise in the spring it will be beneficial to work the soil, so as to admit the air, and trim up any little irregularities of growth.-CHARLES BALTET, Troyes.

HELIOPSIS SCABRA MAJOR.

THIS is a beautiful autumn-flowering composite, and one that will doubtless become a favourite in many gardens. Several bunches of blooms of Heliopsis scabra major were exhibited at a meeting of the Royal Horticultural Society on September 26th by Mr. B. Ladhams, High Street, Shirley, near Southampton, and for which the Floral Committee adjudged an award of merit. The deep yellow flowers are from 2 to 3 inches in diameter, and have a slightly conical disc. For the embellishment of gardens this is a most desirable plant, which requires similar treatment to the perennial Sunflower. Fig. 55 represents the flowers.

SUCCESSFUL LEEK CULTURE.

LEEKS are favourite vegetables in many British gardens, but their culture does not generally receive the attention it merits in the South of England, for of all the Onion family a well grown Leek is one of the most wholesome and delicious we can have upon the table. In Scotland Leeks are cultivated with a considerable share of success, in fact their importance is recognised in gardens of all sizes, and either there or in the northern counties of England can this vegetable be seen in perfection. With the counties of Durham and Northumberland we are most concerned in the present article, because in few districts is so much interest taken in Leek culture as there, especially in the Valley of the Tyne and the immediate neighbourhood of Newcastle and Gateshead. During the concluding weeks of September and throughout October scores of shows are held there entirely devoted to displays of this vegetable, where hundreds of growers meet in friendly rivalry to test the respective merits of their products. For a period of several weeks considerable excitement reigns, the successes of wellknown growers form the chief subject of conversation, and the qualities of the winning exhibits are most keenly criticised.

Much interest is imparted to these shows by the fact that the prizes almost invariably consist of articles useful for the homes of the competitors, and as on the day of the show all the prizes are displayed in the room they alone furnish an exhibition of an exceptional character. They comprise elaborately ornamented clocks, tea and dinner services, silver teapots, copper kettles (in great abundance, as this is a favourite prize), blankets, silver spoons and pipes. Sometimes a money prize is offered as the first award, or it may appear in the notices very temptingly but indefinitely as "a purse of money." Every exhibit receives a prize, and sometimes as many as 130 are thus awarded.

It may be imagined that the task of the judges is not exactly a sinecure, when it is stated that the exhibits have all to be arranged in strict order of merit from 1 to 130, the value of the prizes being graduated in proportion. The work must be performed with the greatest possible care, as every one of the competitors is no mean judge of what a good exhibition Leek should be, and requires ocular evidence why No. 99 is placed before No. 100. If the necessary difference cannot be discerned the discussion amongst these hardy north countrymen becomes rather lively, and the judges would find it more convenient to be out of the way. In the south of England judges of great experience frequently complain of the difficulty they find in selecting five or six prizewinners from twenty exhibitors, but what would they say if they had to award 100 prizes in order of merit? The task seems to be almost impossible, and no doubt there are sometimes cases open to question, but these are rare, and as a rule when competent Leek

judges are employed, and they have plenty of time for their work (they sometimes take three or four hours), there is little cause for complaint.

Three Leeks are invariably required from each exhibitor, and the utmost endeavour is made to obtain these exactly alike in appearance, length of blanching, and diameter. It is common to see specimers as much alike as if they had been cast in one mould, pure white, 12 to 15 inches long, and 2 to 3 inches in diameter. The principal show is held in Bensham during October, and for the three days the place is visited by thousands of men, some of whom come a considerable distance, and at night the crowd is so great

FIG. 55.—HELIOPSIS SCABRA MAJOR.

that they have to be let in by batches, the approaches are blocked with visitors, and constables are especially appointed to regulate the traffic.

The majority of men engaged in this work are cottagers, pitmen, mechanics and other workers in the district. The method of culture is especially interesting as showing what can be accomplished by close care and attention by men who had no training in gardening, and who often know little respecting it beyond this matter. They make it a hobby, however, like the Gooseberry growers of Lancashire, and with more useful results, for one of these prize Leeks, or indeed any of them, is an important article of food where good vegetables are never too abundant.

All the principal growers save seed from their best selections, and each therefore has a special strain of his own with which he will not readily part, and which he considers to surpass all others in some characters that he can readily point out.

The seed is sown early in the year, usually at the end of January, during February, or a little later. It is only from the earliest

sowings that the best results are expected. Light soil is employed for filling the pots rather firmly, and the sowing is made in a frame, or where that luxury is possessed, in a small greenhouse. As soon as the seedlings appear, and are large enough for the operation, they are placed singly into small pots and afterwards very carefully transferred into large-sometimes 12-inch-pots, in which they remain until planted out. While under cover they are watered when necessary, and ventilation is freely provided in fine weather, but at the same time every care is taken to avoid any kind of check. It is the same in the shifting or repotting, as the Leek is very sensitive to root injury, as all who are engaged in the ordinary outdoor cultivation know quite well.

Trenches are prepared by taking out the soil $2\frac{1}{2}$ feet deep and wide. The lower part is filled with stable manure, and over this is placed the well-prepared fine rich soil in which the Leeks are planted during May. The sides of the trenches are boarded, and fine soil is added as the plants advance to insure the due lengthening

and blanching of the stems.

Two rows of Leeks are placed in each bed, 1 foot between the plants, and in the centre are inserted several small earthenware drain-pipes reaching to near the base of the soil just above the manure. To a novice the object of these pipes is rather puzzling, but their use soon becomes apparent. When the Leeks are advancing in growth they are encouraged by liberal applications of liquid manure, sheep's manure being preferred when procurable. avoid saturating the soil around the delicate stems, and thus causing discolouration, the liquid is poured into these pipes so as to reach the roots direct.

As the exhibition season approaches the plants are carefully examined, and the most promising receive special attention. The soil is raised round their "necks," and cotton wool is placed in the axils of the lower leaves to prevent moisture accumulating and causing decay. Then when lifting time arrives the stems are well washed and bad leaves removed, but after the cultural period is passed Leeks undergo comparatively little dressing to fit them for the shows, and if it is evident that much manipulation has been practised it tells against them for the better prizes.

The men engaged in this work derive much pleasure from it, and also some advantage, for they all grow many more than are needed for showing, as they are greatly appreciated in their homes, and some gain far more than they expend by the sale of surplus plants.—WANDERER.

A WARNING TO ORCHID HUNTERS.

In consequence of the depredations of Orchid hunters and other collectors, Rajah Brooke of Sarawak has, it is said, decided to prohibit the collecting of natural history specimens within the He has, moreover, taken stringent measures with a view to preserving the fauna and flora of the country, many species of which were in danger of becoming extinct owing to the ruthless manner in which they were being destroyed.

ONCIDIUM SANDERIANUM.

According to the "Garden and Forest" this is an introduction from Venezuela, where it is found growing at a great altitude, and at a very low temperature. It is said to be a free-flowering species, producing thickly branched spikes, which are covered with rosy-red blossoms; in form somewhat reminding one of Odontoglossum Pescatorei. Several plants of this Oncidium have lately been sold at auction. It is in the way of O. zebrinum in habit, but the pseudo-bulbs are more wrinkled and distinctly egg shaped. Apparently it is new to cultivation, and from the collector's description it ought to prove a good garden plant.

CYPRIPEDIUM H. BALLANTINE.

Those persons who have seen this beautiful Cypripedium will agree with me that it is one of the best hybrids in cultivation. It was raised by Messrs. J. Veitch & Sons, and is the result of a cross between C. purpuratum and C. Fairieanum, the latter being the pollen parent. In habit the plant is dwarf, out the flowers are exceptionally noticeable. The dorsal sepal resembles that of C. purpuratum, but also possesses characteristics of the other parent. The petals and lip are very distinct. So far as I have seen this hybrid has not yet found its way into collections generally, but this it will doubtless do in due course.-C.

ORCHIDS AT WOOLTON WOOD.

THERE is at present in flower at Woolton Wood a curiosity amongst the Orchid family, viz., Lissochilus giganteus, a native of the Congo, and one which has been flowered only a few times in England. It is growing in an 8-inch pot, the pseudo-bulb and leaves having a striking resemblance to a half perfected growth of Peristeria elata. From this pseudo-bulb there is a spike which has reached the extraordinary length of 9 feet 3 inches, at the top of which are thirty-six of its peculiarly shaped flowers. Although not beautiful, it is a great curiosity and worthy of being grown on that account. The culture the Lissochilus receives is as follows: It is potted in a mixture of rough peat, decayed cow manure, crocks, harcoal and sand. Whilst growing it is supplied with abundance of water. As soon as the flowering is over it is kept dust dry. plant is growing in a stove temperature.

A choice collection of Cypripediums is also grown, the following being in flower, viz, Ashburtonæ, Œnanthum superbum, Crossianum, Domini, expansum, caudatum, Spicerianum, Niobe, and Morganæ Burfordensis. Other well flowered plants are Cattleyas Bowringiana and Alexandræ, Odontoglossum grande, and a very fine variety of Vanda Sanderiana. Mr. Todd, the head gardener, is to be complimented on so choice and healthy a collection.—

R. P. R.

ARE TOMATO DISEASES CONTROLLABLE?

THE lucid argument contained in the communication from "Hygienist" (page 325) contains much matter for reflection. graphic description of Bacterium Halstedi, by Mr. Abbey (page 350), is preserved most carefully by me in case of future emergencies. Had he desired specimens of Chrysanthemum buds I could have supplied him; his information is most valuable, and his future communications on the diseases of the Tomato will be looked

forward to with great interest.

While I am decidedly of opinion the Cladiosporum and Phytophthora can be to a large extent controlled, I should be sorry to claim, with Mr. Buss, that these diseases can be prevented by the ventilator or watering pot. It is an easy matter for cultivators to "talk big" after such a season of phenomenal weather. I know several cases where Tomatoes have grown naturally from seeds in the soil, and developed three trusses of fruit during the In an ordinary season, unless a cultivator vigorous plants in 5-inch pots, he is unable to secure a crop. till we have another 1888 or 1889, when the crops were practically failures, and see how many persons we can find who will assert they have mastered their enemies with the ventilator and watering pot. At the same time I wish it to be distinctly understood I am precisely of the same opinion as "Hygienist" and Mr. Abbey that the method of culture accorded has much to do with the development or otherwise of plant diseases, and I trust that at some future date Mr. Abbey's investigations may enable him to point out a preventive or remedy for this and other kindred diseases. It appears to me, it is only when we get a combination of the practical and scientific man the investigations are likely to prove valuable to the general body of cultivators.—J. B. R.

PEARS VERSUS PEACHES.

SINCE the publication of my article on this subject (page 259) much useful information has been disseminated by various correspondents, but several of them have failed to grasp the purport of my remarks. Mr. Molyneux, for example, on page 287 appears to have overlooked the fact that I was merely suggesting the culture of Pears on walls in preference to Peaches, where the latter generally failed, and cited a few cases in support of my suggestion. I do not doubt your correspondent's assertion that in his case Peaches are more remunerative than Pears, because I happen to know they are usually so in that locality; but it does not alter the facts mentioned in my notes. There are two sides to the question, and whilst Peaches fail to thrive satisfactorily in certain gardens, it does not necessarily follow that "the trees are not managed in the proper way," or the "judgment misplaced." Much could be said on this point, but space is valuable at Chrysanthemum time, and I will merely say that the trees in the gardens mentioned in my previous article were "properly managed" in every detail, and were not dispensed with until after years of experience, and careful consideration had been given the matter. As before stated, choice Pears have since been planted in their stead and have proved "infinitely bctter.

In corroboration of my remark that "opinions vary according to experience" on this matter, I need but refer to a few instances. Mr. Molyneux on page 287 makes the assertion that "As much as gardeners." think of Maric Louise Pears, there is great difficulty in inducing fruiterers to buy them." Curious to say on the preceding page (285) another correspondent, "B.," in referring to early Pears says, "I have planted several trees of Marie Louise, the most useful of early winter Pears. It

is seidom we have too many of this, as it ripens slowly; and its season is easily extended by a little care in gathering, and by keeping the later fruit cool. Moreover, no Pear sells better, as it holds a high character in the market." The latter sentence is obviously in conflict with Mr. Molyneux's experience, and it would be interesting to have the opinion

of others on this point.

Presumably the same correspondent, "B.," deals with the question at some on page 309, and in the main agrees with my suggestion, as will, I venture to say, many northern gardeners. In the same issue "R. P. R.," writing from the neighbourhood of Liverpool, points out clearly the advantage of Pears over Peaches on walls; and while that is but a single case in point, it will add weight to the discussion. Mr. Molyneux I believe has, like myself, had some gardening experience north of the Trent, and he will perhaps say whether he has grown Peaches, or seen them cultivated, on walls outdoors as well in the northern counties as he can manage to produce them in Hampshire. "Y. B. A. Z." and "W. S.," on page 309, are in favour of Peaches, as will doubtless be other correspondents who reside in such favoured counties as Somerset and Wiltshire, but even these may have found, and doubtless will find, that all seasons are not so conducive to successful open-air Peach culture as has been 1893.

Another case in support of my contention might be mentioned. In the Journal of Horticulture last week (page 353) a paper which Mr. G. Bunyard of Maidstone read before the Horticultural Club is printed. In this Mr. Bunyard refers to certain varieties of Pears as being exceptionally fine this season, and remarks, "The palpable lesson here is that we ought to place all such good but 'difficult-to-grow' sorts on south or south-west walls, where they would in many cases do better than Peaches and Nectarines." When we find such an authority on fruit culture, and a resident in "sunny" Kent, advocating the culture of choice Pears on south walls in preference to Peaches it is not at all surprising that northerners have found it to their advantage to do likewise.—C.

"R. P. R." (page 309), in his closing remark anent the sale of Williams' Bon Chrêtien and Pitmaston Duchess Pears in the leading Liverpool fruiterers' shops, is not quite clear on the point. mean that the fruiterer has been receiving 3d. and 6d. each for thesc Pears? I take it that is what is meant; but how about the grower? The prices quoted do not give any information how that individual fared. He is the person whom the subject of "Pears versus Peaches" most concerns. If the prices quoted are those received by the grower, then there is just reason to say that Pears are more worthy of attention from a market point of view than Peaches. I saw but a few weeks since some fine Duchesse d'Angoulême Pears being sold for 1d. each. This was what the grower received, and from one of the best fruiterers on the south coast. What the latter sold them at is another question. My business is with the grower, and I suspect this individual was solely What the latter sold them at is another question. in the mind of "C." (page 259) when he started this interesting controversy.

I, like "Y. B. A. Z." (page 309), regard Bourre Diel as worthless as a dessert Pear. Even in the most favoured soil for Pear culture it is inferior to such varieties as Doyenné du Comice or Marie Louise, but in soil that is unsuited to its constitution it is not worth the room it

occupies.

In my opinion "blister" on the Peach leaves is caused mainly, if not quite, by east winds. Some two or three years since we had no east winds one season at the critical period, and we experienced little or no "blister." My plan when disbudding trees addicted to "blistering" is to leave an extra number of shoots for a few weeks until the trees have passed that stage. We can then afford to remove entirely the worst of the "blistered" shoots. In cases where the leaves only are affected, these are picked off directly they are injured. Upon the advent of more genial weather the shoots grow out of the "blister." The practice of leaving an extra number of shoots at disbudding time is decidedly advantageous, and one that cultivators troubled with blister would do well to adopt.—E. MOLYNEUX.

PEACH-LEAF BLISTER.

I HAVE pleasure in responding to the invitation of "Y. B. A. Z." (page 309) to give my views on the cause of Peach-leaf blister, prompted, as he evidently is, by a desire to arrive at the truth. "What is Peach blister?" asks Mr. Edward Luckhurst in the Journal of Horticulture of June 22nd, 1876, page 481, then proceeds to answer his own question as follows:—"It is a disease affecting the foliage only when young and tender, appearing in the form of blotches or blisters irregular in form and size, being sometimes as small as a pea, and occasionally spreading over an entire leaf. The affected part, having a pale sickly appearance, becomes much thicker in substance than the healthy part, and rises into a convex form precisely similar to other blisters. It is distinct from all other forms of blight, and cannot be mistaken." Mr. Luckhurst next asks, "What is the cause of Peach blister?" and again answers, "It is caused by the exposure of the expanding foliage to the influence of frost or cold cutting winds." Evidence in proof of this conclusion is then given. 1, Trees on a west wall had "fine foliage, perfectly clear, and quite free from blister or blemish of any kind." 2, Trees against an outer south wall, "along which the cold east wind swept unchecked," had the leaves much blistered. 3, Trees on a south inner wall had the leaves quite sound near the east end, "but further on where the trees were more exposed they were affected precisely in proportion to the extent of such exposure"—that is, to the cold east wind.

Whether "Y. B. A. Z." had Mr. Luckhurst's article in mind at the time of writing on page 309, matters little; but I consider it important that all evidence bearing on the subject be given due consideration. Therefore a few brief notes on Mr. Luckhurst's article may be made with profit. From a cultural point of view there is nothing in the article referred to to which exception can be taken. Mr. Luckhurst tells us to "watch the development of an organ [foliage] upon the condition of which everything depends—the crop, the growth, the very existence of the tree itself, to cherish it by every means in our power, to cleanse it from insects with a prompt and ready hand, and to screen it from frost and cold cutting winds." That is good cultural advice, but all the same Mr. W. G. Smith had proved that fungus was the cause of Peach leaf blister, and exploded the opinion that had prevailed up to that time—namely, "the blistering being caused by spring frosts rupturing the sap vessels and the fungus living upon the extravasated sap." Mr. Smith's explanation and illustration of Peach blister with accompanying fungus (Ascomyces deformans) will be found in the Journal of Horticulture of July 8th, 1875, and he, following De Bary and Berkeley, practically settled the question on a sound basis.

I think it necessary to make the foregoing observations in justice alike to Mr. Smith and Mr. Luckhurst, for it is not right that we should profit by the teachings of others without giving expression of our indebtedness. This gives me an opportunity of saying that the little I know about fungi and the diseases caused by this class of parasites is mainly due to studying the works of the late Rev. M. J. Berkeley, Dr. Cooke, and Mr. W. G. Smith. Information has also been derived from articles appearing from time to time in the Journal of Horticulture and in the Gardeners' Chronicle. Most of the subjects treated by the specialists I have endeavoured to study on the plants the parasites infest, and produce disease on or in, and the result in all cases has been a verification of their teaching, and conclusive proof of the desirability of acquiring

scientific knowledge as well as cultural practice.

Mr. Smith has given decisive proof that all the exposure of the expanding foliage of the Peach to the influence of frost or cold cutting winds was capable of producing a favourable medium for the growth of the fungus. This may seem to confirm Mr. Luckhurst's contention that the fungus was consequential and not initiatory of the disease. But it is at this point where the great gulf exists between cultural conjecture and scientific fact. Who has ever seen the young growths of any tree blistered and distorted without a cause? The east win1 never produces anything beyond a stunted and crippled growth. There is no blister without its cause, the growth of the mycelium of the fungus within the leaf and shoot tissues; no curled leaves and distorted growths without the causing parasites or insect pests. While approving of the cultural advice given by successful Peach growers I have to say that the Peach tree leaf blister is not caused by cold or east winds, but by a fungus. This enemy is not confined to this country, but is found on Peach trees on the continent under the name of Exoascus deformans, and in America under that of Taphrina deformans. The continental trees against walls receive similar protection to that given in this country; in America the trees are grown as low standards, and have no protection whatever. In all regions of the earth where the Peach is grown it is subject to attack by the parasite, because the leaves afford it its peculiar food. Surely that is simple enough to be comprehended. The fungus is a plant, endowed with the power of growth and reproduction. It springs into existence from a spore. There is nothing mythical about it. Truc it belongs to a very lowly group of the Ascomycetes family of fungi, but it has great power in producing distortion or deformities in the leaves of Peaches and other trees. We can see the parasite in all the stages of growth as plainly revealed by the microscope. We cannot see the east wind; it is said that pigs can, but as they cannot tell us what there is in it, we will believe what we see-namely, the fungus growing in the leaves of Peach trees and the blistering that follows.

The Peach leaf blister fungus, Exoascus (Ascomyces, Taphrina) deformans, makes its presence manifest by the red blisters on the leaves. These are due to the previous action of the mycelium within the leaf tissues, enlarging and multiplying the cells, giving rise to the thickening and swollen condition of the leaves. The first indication, however, of an attack by the fungus is an abnormal growth, a thickening and deepening of colour in the leaves. There is no pale sickly hue such as results from exposure to cold or the presence of aphides, for sickly leaves arc of no use to the fungus, as it lives upon the chlorophyll. This the mycelium destroys, and red colouring matter takes its place, as seen in the Ultimately, the mycelium or outgrowths from it burst through the cuticle or skin of the leaf, and appears as a fine pale bloom, visible chiefly on the lower surface. This consists of a stratum of fine threads, from which spring innumerable erect, slender flask-shaped bodies (asci), each supported on a shorter cell. Each ascus contains eight minute oblong spores; these, escaping by an orifice at the apex, go forth to reproduce the fungus. In addition to asci, other necklace-like growths spring from the threads, and consist of simple cells or spores, which are considered by Mr. Smith to be capable of reproducing the fungus. Excellent illustrations of the attack on the leaves and of the fungus will be found in the Journal of Horticulture, vol. xxviii., new scries, page 31, by Mr. W. G. Smith.

The leaves covered or attacked with Exoascus deformans wither and fall off prematurely. The period of attack is confined to the spring or early summer, for when the weather becomes warm and settled the growths start freely and the leaves are not attacked by Exoascus deformans. This has led to the erroncous conclusion that the fungus spores are only able to act on tissues impaired by cold weather. Frost

either kills tender growths, or causes the leaves and fruits to sicken and drop. Cold contracts—stunts shoots and cripples leaves. How the spores of Exoascus deformans can push their germinal tubes through the cuticle of a leaf when it is contracted—drawn tight to resist the cold or enter the leaf tissues by the stomata when these are closed, is more than I am able to understand. But this is wholly outside the subject, for cold weather has nothing whatever to do with the fungus any more than it has with certain species of Crocus flowering in the spring and others in the autumn. Yet there is said to be a predisposing cause. What is it? Who does? But I do know that there is a fungus—a I do not know. plant—named Exoascus deformans by botanists, which is raised from seed (spores), requires a Peach tree to grow in, lives on chlorophyll, and produces its blossoms and fruits during the early summer months. It is a perennial—the mycelium lives in the tissues, and the disease reappears year after year on the same branch or tree.

Now I should like a little information. Whence come the spores? From sunny France? The balmy East? Where does the east wind pick up the spores? It is no use appealing to the wind! What about the trees on walls in this country? Are there not any decrepit—half dead in branch, distorted in shoot, and blistered in leaf? Is it from these that the spores are wafted by the east wind and disease set up in trees situated westward? Why, then, do not west winds convey the seeds of disease eastwards? The spores must come from somewhere, and it is certain they cannot bear the drought of summer nor the cold of winter, for they are naked cells, and must soon do or die. That is one reason the fungus does not raise blisters on the leaves of Peach trees grown against walls in the summer. It is also completely foiled by a glass roof with careful ventilation in the spring, and it can make nothing of leaves with a stout epidermis. Yet it lives from year to year in the same garden on the identical trees first infested.

There is only this preventive and remedy—cut off and burn the blistered leaves before the bloom appears on the red warts, also cut off and destroy the diseased shoots or branches. By one the spores are got rid of, and by the other the perennial mycelium. As for dressings, winter applications can be of no use, and as Peach foliage is very tender in spring it would not be safe to employ a Bordeaux mixture at greater strength than the following: Sulphate of copper, 4 ozs.; quicklime, 4 ozs.; water, 15 gallons, using as a spray.—G. ABBEY.

SUMMER AND WINTER BEGONIAS.

I AM very glad that Mr. Molyneux (page 310) is able to report satisfactorily of his Tuberous Begonias. It is a great deal more than could be done in most gardens out of Hampshire I am afraid. True, the very favourable autumn with its warmth and heavy rains has greatly improved the beds, and like the field Mushrooms Begonias have been having a better chance lately than they have had all the season. Some tubers lifted a few days ago in a garden I was in illustrated in a very remarkable degree the evil influences of the drought. The only growths they had been equal to pushing were 3 to 4 inches long, doing little more, in fact, than getting fairly through the ground, and about as thick as my pencil. Fortunately they were not all like that, otherwise the beds would have been completely bare.

I can only hope that the improved aspect which Begonias have assumed late in the season will do something to redeem the bad impression which many must have formed of them in the full flare of this searching summer. There has by no means been a universal failure. Not far from where I am now writing there is one of the most beautiful front gardens which I have seen attached to a small villa, and its chief occupants are Begonias, and if an exception on a larger scale be required it may be found in Messrs. Cannell & Sons' Nursery at Swanley. have thousands of plants blooming in the beds, presenting both to those on the adjoining railway, and to those in the nursery itself, a very rich and warm glow of colour.

It is to be particularly noted how much better the doubles have done than the singles. Where many of the latter are stunted and ill-clothed with foliage and bloom the former are fully furnished with both leaves and flowers. It is well worth while to give this fact due consideration, for the plants have had the same chance in every way. This would point to the advisability of giving special attention to the doubles for bedding, and also to the necessity for selecting some of the best and most distinct types of them. The Swanley growers have risen to the occasion, as they generally do, and have chosen some varieties of vigorous but even, compact growth and of pronounced free-flowering qualities from the mass of material in the beds with a view to giving them special recommendation for outdoor growth. Their action may be cordially endorsed, for there is no question of the superior effectiveness of beds furnished with floriferous and well balanced plants, bright and decided in colour, to others filled with a heterogeneous mixture (if such a phrase be permitted) of seedlings, some of which are strong growers, others weak, some tall, and some short.

As instances, four new selections, all doubles, to which varietal names have been given may be mentioned. One is Freedom, a salmonpink free-flowering dwarf sort, with a growth as even and level as a Tom Thumb Tropæolum; a second is Attraction, brilliant orange, also dwarf, bushy, and floriferous; a third is Erecta, a rose-coloured form, of taller and more upright growth than the others, but very even and level; and a fourth, Red Shirt, a scarlet semi-double, covering itself with flowers. These are very conspicuous in the beds, being as regular in growth as a number of market Genistas or Pelargoniums, and easily to be picked out in their lines. Messrs. Cannell & Sons are doing good work with these special selections of bedders.

Their collection under glass is also a very extensive one. They have five of their long houses full-or rather had, for the structures are now being rapidly cleared—besides several more at Eynsford, where, the head of the firm tells me, his son has fairly beaten him with the quality of his plants. Paterfamilias seems rather proud of his defeat. Eynsford plants must be good, for those at Swanley, or such as are left of them, are a very beautiful collection. The great majority are grown in 5 and 6-inch pots, no special culture being attempted, but preference given to smaller plants, in order that their true qualities under ordinary cultivation may be estimated. A few of the best of the doubles are R. B. Parsons, bright pink; Miss Cochrane, peach, very large; Lady Osborne, rosy salmon, a very distinct shade; Lord Haddo, bright rose with creamy flakes, one of the Carnation-flowered breaks; Rosebud, pale pink, a familiar variety; Miss E. Wynne, white, crimped flowers, a very beautiful sort of drooping habit, well suited for a basket; Miss Lilian Maud, rosy salmon, very large and full; Lady Alice, light yellow, very free; Hon. Mrs. Goschen, creamy, very large and free; Mrs. Lynch, soft pink, crimped; Rev. Mr. Lascelles, clear yellow; Frank Bibby, rich glowing crimson; Octavie, double white, now thoroughly well known; Mr. G. Paul, cream, very large and full; J. Lyon, glowing crimson, very large, full, and fine; and Safrano, light apricot, semidouble. The best of the singles were over, but Albert George (rich orange, very large, and consistently good) and Fashion (a charming orange-amber sort) were conspicuously beautiful. The plants are all from this year's cuttings, so that their fine appearance represents inherent quality, not special cultivation.

Let no visitor to the Swanley Nurseries leave without inspecting the house of winter-flowering varieties, for it is already a beautiful sight, and will improve as time goes on. This valuable class is growing steadily in popular esteem, and if anything were wanted to prove their usefulness and charm the house referred to will supply it. The collection is one of the best in the country without any doubt. As might be expected Gloire de Sceaux plays a prominent part. Those who have had opportunities of estimating the effectiveness of this grand Begonia naturally look for it wherever they go, forgetful that all gardeners have not had the same chances, but it is only a question of time for it to become a universal favourite. Carrièrei is a totally different type of plant, the foliage being smaller, and the habit more bushy. Plants in 5-inch pots are a foot high and 15 inches across, being, like well-managed Cyclamens, broader than they are high, and, moreover, quite clothed with bloom. It is a very valuable sort. Weltoniensis is too well known to need comment, and so is nit'da; but there are two of the semperflorens type less familiar; one is S. gigantea rosea, which has very large bright green leaves, and abundance of rosy flowers; the other is a sort named Laura, the foliage of which approaches heart-shape, and the flowers are pink. It is a true winter bloomer. These are six of the best, but that there are many others in every respect well worthy of culture a call will at once suffice to prove.—W. P. W.

COLD HARD WATER FOR PLANTS.

MR. DUNN's last communication (page 361) on the subject clearly shows that a little more reflection on the matter may prove of considerable service to him. He has not proved a single idea he set forth, but, on the other hand, it has been conclusively proved that many practical growers, well known and respected in these pages, do cultivate their plants and crops successfully, using water such as he condemned.

Mr. Bardney (page 361), with his usual judgment, now appears on

the scene in a very conciliatory mood, but I should like to remind your able contributor that I have never suggested the use of cold hard water during the winter months. My contention was that it can be, and is, used between the months of March and November successfully. My object in writing was to prove that Mr. Dunn's pet idea had led him

beyond the bounds of prudence and modern practice.

In reply to "T. A." (page 340), I am able to state practically that the water of the New River Company does contain a large per-centage of lime, in fact the river has its origin at the foot of a chalk hill. This water when used in Hertfordshire will leave a white deposit on the leaves of plants, and there can be no doubt it is very hard. The water of the East London Company never sees the light till it is applied to our plants, and is, as I stated in a previous communication, very cold. It is also very hard to the touch, but it does not leave the white limy deposit on the leaves like the New River water .- J. B. R.

ONE of your correspondents mentioned that water impregnated with lime "burned the rootlets of plants." Does lime in water burn the rootlets of plants? I hardly think so, or it would not be recommended as harmless as a "slugicide," doing no injury to plants. Some plants thrive amongst lime, while it kills others, Heaths, for example; instead of lime in water "burning," is it not rather a case of petrification?

I have always been of opnion that in watering artificially the temperature of the water should never be less than that of the soil the roots are in. For syringing, I think the water should be a little warmer than the temperature of the air either inside or outside. I have watered with cold spring water during a drought, but failed to see any good arising. I know of several springs differing in temperature to the extent of 20°. Is "pure" water proper food for plants? Very few waters are pure; they soon contract impurities or foreign matter when formed into rain drops or pass into streams.—T. N. B.

EVENTS OF THE WEEK.—The principal events of horticultural interest during the ensuing week will include several Chrysanthemum shows. The first one, Havant, will be opened on Friday, the 28th inst., and others will follow in quick rotation. A list of some of the most important exhibitions, and those that have been advertised in our columns, is given on page 380 of the present issue.

- THE WEATHER IN LONDON.—The weather has been mild during the greater part of the past week, and much rain has fallen in the metropolis. On Sunday it rained more or less nearly all day, but was fine on Monday. Tuesday proved colder, and Wednesday opened similarly, it heing also dull as we are preparing for press.
- LA SOCIETÉ ROYALE D'AGRICULTURE ET DE BOTANIQUE DE GAND.—At a meeting of this Society, held on the 16th inst., Mr. H. J. Veitch, of the Royal Exotic Nursery, Chelsea, was unanimously elected a *Membre d'Honneur*, in recognition of his services to botany and to horticulture.
- AMARYLLIS BELLADONNA.—Mr. W. H. Divers, Ketton Hall Gardens, Stamford, writes:—"A narrow border of this plant at the Mote Park, near Maidstone, formed a very pretty, as well as an unusual sight, last month when the plants were in flower. Mr. Fielder grows it on a south aspect close to some warm Orchid houses, which no doubt assists it to a certain extent during the cold weather, and also helps to ripen the bulbs in the summer. The plant has one bad point, as it flowers at a time when it has no foliage, but this may be assisted in various ways so as to give full effect to the flowers."
- Mr. James Veitch, of the well-known firm of Messrs. J. Veitch & Sons of Chelsea, who has been travelling in search of plants all over the world for some years, has collected plants from that part of the globe. They were packed in twelve large Wardian cases, weighing over half a ton each. The dimensions of each case are 4 feet by 2 feet 6 inches, and 2 feet 6 inches high. The twelve Wardian cases mentioned were shipped by the "Ruahine," from Lyttelton, for London, by which vessel Mr. Veitch was also a passenger. [We learn with pleasure that Mr. James Veitch has arrived home safely, also the plants, to which a further reference will be made.]
- THE FIRST INTERNATIONAL BOTANICAL CONGRESS ever convened on American soil was held at Madison, Wis., immediately after the adjournment of the American Association for the Advancement of Science, August 23rd and 24th. The foreign representation, however, was so small that the title of the meeting was changed to the "Madison Botanical Congress." The meeting was an outgrowth of that at Genoa last year. Professor E. L. Greene of California was elected President. All the subjects discussed at the meeting referred to terminology, the following being the topics:—1, Plant Diseases; 2, Anatomy and Morphology; 3, Physiology; 4, Horticultural Forms; 5, Bibliography. It is expected, says "Nature," that the next meeting will he held in Europe in 1894, but the precise time and place was not announced.
- The Best Country for Apples.—It is said that California will never get the fame in Apple culture which has followed its experience with other fruits. This is natural; the Apple is a native of cool and comparatively northern regions. It has never been able to adapt itself to warm countries. Even in the Eastern States the Apple is not a particularly successful fruit south of the Potomac river, except in the mountains and cool regions. All along the Allegheny range they thrive admirably, quite as well as in the famous Apple regions of western New York; but when we get into the lower lands, where a long and comparatively high summer temperature prevails, the Apple would never be looked upon as a desirable orchard fruit hy those who were looking to profit from fruit culture. Thus remarks "Meehans' Monthly," and by way of a supplement we might put in a claim that England is at least one of the best countries in the world for Apples. This year they have in most localities been exceptionally fine.

- GARDENING APPOINTMENT.—Mr. William Seal, five years foreman for Earl Stanhope, Chevening Park, Kent, has been appointed head gardener to S. W. Waller, Esq., Baynard's Park, Surrey.
- —— CURIOUS SPELLING OF THE NAMES OF PEARS.— In a fruiterer's shop in a Suffolk town I noticed the following three Pears very well represented—Chaumontel, Beurré Diel, and Bergamotte d'Automne, hut curiously labelled "Sharman's Tell," "Bure's Dale," and "Burgoyne" respectively.—EAST ANGLIA.
- —— GAILLARDIAS AND ANTIRRHINUMS.—These are still in flower and have been so since the spring. They appear to have almost enjoyed the very dry season, and have proved most useful for cutting when nearly everything else was hurnt up. A bed of Yellow Prince dwarf Antirrhinums has been much admired.—EAST ANGLIA.
- —— Self-sown Tomatoes.—Mr. G. F. Ash, The Gardens, Swanhourne House, Winslow, Bucks, informs us that he had self-sown Tomatoes which came up in the open garden, and one plant was simply staked and in no other way protected. This produced 130 very large fruit of the old wrinkled red type, and many of them ripened.
- —— ACCORDING to the "Lancet," the APOTHECARIES' SOCIETY are about to apply to the Courts for powers to sell their Botanical Gardens at Chelsea, the money value of which has been fixed at about £30,000. The removal of this historic garden would be a source of keen regret to the many who have profited by the instruction conveyed by its means.
- Belladonna Lily.—"T. A., Bristol," writes:—A few seeds of this plant have ripened here this season. I should be glad to know if it is unusual, as I do not remember to have seen in previous years any capsules attempting to swell much less to perfect their seeds. These are about the size and form of the small round grained Maize, and when first gathered are of an ivory white colour.
- JOHNSON'S GARDENERS' DICTIONARY.—A copy of part vii. of the new edition of the above work has come to hand, and like its predecessors, it has heen carefully prepared. It opens with the genus Pleandra and finishes with a description of Sesbanias, the intervening genera heing described in alphabetical order. One more instalment, we believe, remains to be published, which completes the edition. As before remarked, Messrs. G. Bell & Sons, Covent Garden, W.C., are the publishers.
- RIPE STRAWBERRIES IN OCTOBER. Mr. C. Bellwood, The Gardens, East Horsley Towers, near Leatherhead, writes: -In answer to Mr. G. Freeman's remarks (page 355) of discovering several clusters of Strawherries showing colour on the 9th inst., I discovered October 19th several clusters of fruit also in looking over a plot. Some are quite ripe, others not so forward, but I think they will ripen. I may add, the Strawherries were produced from plants that have already fruited in the open, and had not been forced. Mr. John Short, Darlington, also observes:-"I gathered some Strawberries on the 6th, and nearly every day since we have had a few ripe fruits, and there are still quite a number ripening. These are from plants that have been planted out two years. There are other persons in the immediate neighbourhood whose experience is similar. This is the first time we have had any ripe in October for fifteen years." Another correspondent from Bristol says, "My two-year-old plants of Vicomtesse Héricart de Thury have ripened several fruits during the present month, and there are still some to he found in various stages of development; they are rather small, however, and not worth protecting. Neither Noble nor any other variety has given a second crop of fruit with me." In addition to the foregoing, other instances of Strawberries fruiting this autumn have come under our notice.
- POTATOES IN LINCOLNSHIRE.—We learn from a northern contemporary that the Potato harvest in the Fen district of Lincolnshire is now completed "Generally speaking, it has heen one of the hest experienced for several years, and those who risked planting a large acreage with the tuber have had no cause to regret having done so. The early varieties especially made some very high prices, and several growers made as much as £20 per acre, exclusive of the cost of digging the crop. The season has been an exceptionally favourable one, and owing to the absence of rain very little disease has been noticed, and consequently less labour has heen required for picking and sorting. Magnum Bonum, which is a variety much grown in the Fen district, has yielded heavily, and there are numerous instances—notably amongst allotment occupiers—where the crops have yielded at the rate of 7 and 8 tons to the acre."

- FLOWERS AT DULWICH PARK.—In this park are to be found numerous remarkable evidences of the abnormal season. The Dahlias are still blooming profusely; Zonal Pelargoniums are almost as bright as ever; Weigela rosea is flowering here and there, as also are the Guelder Roses. The beautiful Gentiana acaulis is blooming in different places on the rockeries; whilst Roses, especially of the Monthly types, are numerous.—W. J. K.
- HORTICULTURE IN GERMANY.—A continental contemporary says that Dr. L. Wittmack has been charged to furnish for the exposition at Chicago statistical instructions upon horticulture in the German empire. His highly remarkable work comprehends all branches of horticulture. Amongst other things, it is stated that Germany contained in 1892, 17,699 horticultural establishments and nurseries, employing about 45,000 employés.
- —— Dahlias from Tottenham.—Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, N., sent us last week a box of Dahlia blooms, comprising those of the decerative, Cactus, and Pompon types. The flowers were exceedingly fresh and beautiful for the late period. Among the Cactus and decorative varieties were Mrs. F. Vince, purplish pink; Mary Picton, lemon yellow; Baron Schröder, bright magenta; St. Catherine, yellow suffused red; Beauty of Arundel, magenta, deep centre; and Mrs. Keith, salmon pink, lemon yellow centre. Of the fine selection of Pompons, Revenge, Eva, Marion, and Little Sweetheart were the best.
- LIGUSTRUM IBOTA.—Our transatlantic contemporary, the "Garden and Forest," has an excellent illustration of this plant in the issue for October 11th, and remarks that the North China and Japanese Ligustrum Ibota is certainly one of the best exotic shrubs introduced into our gardens for many years. The long, slender, arching branches give to it a light and graceful habit in marked contrast with that of the other species of this genus, which are usually stiff and rigid in habit. Late in the month of June, from the end of short lateral branches, the clusters of white flowers hang in great profusion, giving to the plants a charming effect of grace and lightness. The flowers are followed by abundant blue-black berries, which remain on the branches until the beginning of winter, and make the plant interesting during several of the autumn months. It America Ligustrum Ibota promises to grow to a height of 8 or 10 feet, although, as it appears in the mountains of Japan, where it is by no means a common plant, it rarely rises to half that height. Ligustrum Ibota will, perhaps, become as completcly naturalised in some parts as Ligustrum vulgare and Berberis vulgaris have become naturalised in eastern New England, for when they are planted in semi-wild situations numerous seedlings spring up, and are able to hold their own against the encroachments of native plants. This Japanese Ligustrum may be safely used whenever large, hardy, fast-growing shrubs are needed.
- THE RHINE TIMEYARDS.-A German official return relating to the value of the Government vineyards in what was formerly the Duchy of Nassau, now a part of the Prussian district of Wiesbaden, is summarised in a recent report from the United States Consul at Mayence. The total net profit from all the crown vineyards during the last twenty-four years amounted to £94,225, or £3,926 per year in round numbers. These vineyards have an aggregate area of about 192 acres, which would make the average net profit annually per acre about £20. Taking the estimated value of the vineyards to be approximately $\pounds628$ an acre, $3\frac{1}{4}$ per cent. would be the average annual rate of income derived from them. But these vineyards are amongst the very best in the country, and their produce commands commensurately high prices. The expenses connected with the management of them are great, and the capital they represent is considerable, but their wines are of the finest, and are in great demand. These wines bring the highest prices in the market, being sold for the most part directly to the consumer, thus giving the coffers of the crown the benefit that would otherwise accrue to the wine-dealer. The ordinary wine-grower is not so favourably situated as the Government, and cannot as a rule make so much out of his property. His wine is much inferior, and his ability to fix his own prices feeble in comparison. It cannot, therefore, be supposed that he makes as much as $3\frac{1}{4}$ per cent. a year on the average out of his vineyards. The vineyards, in fact, are not paying, as only from 2 to 3 per cent. per annum can be made out of them on the average. Many are worked at a loss, as the yield had been inferior in quality or in quantity for some years. The difficulty is that they have been bought at such high valuations that there is no money in them for their owners. The dealer it is who makes the profit.

- WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.— The second meeting of the above Society was held on Thursday last, Mr. R. G. Waterman reading a very able paper on "Soils and Rotation of Crops." As showing the mildness of the season, Mr. Stoney stated that he had that day gathered fine ripe Strawberries outdoors, the variety being Duc de Malakoff. Prizes will be given for essays on various subjects during the ensuing season. The concert recently held in the Parochial Hall, after all expenses—which were heavy—had been paid, left a balance of over £5. A vote of thanks to Chairman and Lecturer closed the meeting.
- AUTUMN RASPBERRIES.—Mr. W. H. Godden, Ledgers, Warlingham, Surrey, writes:—"In last week's issue (page 355) Mr. Freeman gives an instance of gathering ripe Strawberries in the open. I gathered a dish of ripe Raspberries on the 18th inst. weighing 1½ lb., very fine fruit and well coloured, and the flavour was fairly good. I consider this wonderful, considering I am nearly 600 feet above sea level, and clay subsoil." Mr. W. Stanton, The Gardens, Billington Manor, Leighton Buzzard, also writes: "On October 19th I found a large cluster of Raspberries quite ripe, and of fair size. We have had only two slight frosts here. We have had an abundant supply of Runner Beans up till the present."
- LIME SALTS IN PLANTS.—At a meeting of the biological section of the British Association Dr. J. Clark gave the result of investigations on the action of lime on germination in plants, and the existence of lime salts in plant tissue. He had experimented with a number of seeds of Alpine plants with the object of germinating them, and he found that the presence of carbonate of lime in the soil greatly assisted the germination of the seeds of these plants. According to his conclusions upon the question one must in many cases either have a high temperature, to enable the plant to utilise the reserve food supply in the seed, or introduce lime into the soil, which lime helped the transference of food from the seed to the growing parts of the seedling.
- URARIA CRINITA.—This, remarks Mr. G. Nicholson in a recent issue of the "Garden and Forest," is a striking plant with pinnate leaves, not unlike those of the Wistaria, and tall dense racemes of small rose-purple flowers; seeds of this species sown early in the present year have produced stocky, handsome plants with racemes more than a foot in length and about $1\frac{1}{2}$ inch in thickness. The flowers themselves are small and last but a short time, but the very numerous rosy-pink bracts are as attractive, or even more so, before the flowers open, than the latter arc when at their best. The species occurs in a wild state from Ceylon, the Himalaya to China. A figure has been prepared for the "Botanical Magazine." The specific name has been given, owing to the long bristles which clothe the pedicels and sepals. The plant is of easy cultivation in a light, warm house.
- Apples is in accord with that of your correspondent "A." (page 355). Very soon after gathering all my largest specimens, of several varieties, began to decay, the worst being Winter Hawthornden and Nelson's Glory. Some became quite mealy and cracked, others were spotted with dard coloured spots. On the rind being removed these spots were of a brown colour, and penetrated the flesh to a considerable depth. Pears, too, are ripening very rapidly, owing, I suppose, to the warm weather we are having. Marie Louise Pears are all ripe and gone, the quality having been excellent. I have to-day (October 21st) a dish of Huyshe's Prince of Wales quite ripe, which is too early for that variety; and I regret to find Huyshe's Victoria, which usually stands me in good stead about Christmas, much further advanced in ripening than is desirable.—T. S., Bristol.
- Sternbergia lutea is a plant of the season which seems to be much neglected, yet the bulbs are easily secured. They increase rapidly, and a clump in flower is as effective, and not less pleasing, than the Crocus in the spring. The bulbs start into growth in early September, making about 6 inches of leaf growth, the flowers appear in late September. These are something over 2 inches in diameter, are borne on 6-inch scapes, are of a clear deep yellow, and Crocus-like in effect. The leaves are persistent during the winter, and complete their growth in the spring, when the bulbs ripen and become dormant. It is needless to say that bulbs of this kind should be protected from the careless spader. The autumn-flowering hardy bulbs, says a correspondent in an American contemporary, have an unexpectedness in coming into evidence which we are apt to associate with the flowers of spring, and some of them are scarcely less pleasing than those always favourite flowers.

- MICHAELMAS DAISIES .- As with the border devoted entirely to these plants at Chiswiek we planted one here with them last autumn, and undoubtedly this is the correct manner to cultivate and appreciate them at the same time. Owing to the extremely dry weather experienced this summer some of the plants made but moderate progress, especially the larger flowered sorts; these do not appear to be able to withstand drought so well as the small flowering kinds, of which Elegans is an example. Next year we hope for a good display. The roots will by then have become thoroughly established. In addition to those named by "C." (page 349) the following varieties of the A. novæ-belgi type are worthy of a place in any collection—versicolor densus, lilac; formosissimus, deep blue, free and good. Snowflake is especially worthy a place, the pure white blooms are useful in a cut state. Chapmani, pale blue, of loose growth, yet free flowering and good. Elegans, deep lilac, small flowers, wonderfully profuse in its blossoms. Ericoides is one of the best of the late-flowered kinds with pure white flowers, the foliage of this assumes quite a coppery hue, which enhances the beauty of the variety. The best of all, in my opinion, is A. ericoides elegans, pure white and wonderfully free, dwarf in growth. A. alpinus, 1 foot high, is a gem for the rockery. —Е. M.

- PLANT INDUSTRIES IN THE CAUCASUS. - The following interesting particulars respecting the wine industry carried on in the Caucasus are taken from the report of the Statistician of the United States Department of Agriculture for June, 1893 :- Of highest importance for the present and the future of the country is wine growing. The production does not only suffice for home consumption, but supplies to a large extent the wants of Russia, and besides, furnishes a considerable quantity for export. The efforts of Russia for the advancement of this braneh of rural industry are praiseworthy. Under Ottoman rule viticulture could not flourish, as its object was confined to the production of table Grapes, and thus it remained on a level with the culture of other fruits. A changed political situation, introduction of new customs, and the effectual assistance of the Russian Government, have shown the rural population a rich source of income in wine growing. Prince Michael Waronzow, the Governor of Caucasia, procured in the year 1848 120,000 Vines from his own vineyards in the Crimea and from the most celebrated vineyards of Europe, in order to distribute them among the inhabitants of sections adapted to viticulture. Not all of them did well; the varieties have been crossed; but a beginning had been made, an impulse given, and this profitable branch of rural industry has developed gradually to its present flourishing condition. There are still a few drawbacks, otherwise the results of this industry would have been enormous. There is, above all, the Phylloxera, which has made considerable progress during the last few years. The war upon this plague is waged only on the large estates of rich landowners, while the majority of small vineyards is open to the disease. The damage is largest in the governments of Tiflis and Elizabethpol. In Erivan the winter frosts damage the Vines materially. The vineyards of the Caucasus cover an area of 86,000 desatines (232,174 acres), and their annual production is estimated at 13,000,000 vedros (42,237,000 gallons). The average price of Caucasian wine is generally about 25 cents per gallon, and goes up to 30 cents only in years of crop failure. Notwithstanding the faet that a desatine of land adapted to viticulture costs 1000 roubles (182 dollars per acre), this industry proves to be highly profitable, as the net profit averages from 380 to 400 roubles per desatine (70 dollars to 75 dollars per acre).

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 24TH.

THERE was a very fine display at the Drill Hall on this occasion, the building being well filled. Orchids were exceptionally well represented, as were Dahlias and Chrysanthemums. Fruit and vegetables were also exhibited in excellent condition.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair), with Rev. W. Wilks, Dr. Hogg, and Messrs. H. F. Pearson, T. F. Rivers, Arthur W. Sutton, Harrison Weir, G. W. Cummins, J. Cheal, G. Bunyard, G. Woodward, W. Warren, J. Hudson, G. Sage, J. Smith, G. Norman, H. Balderson, A. Dean, J. Wright, and others whose names were not obtained.

Mr. J. Perkins, The Gardens, Thornham Hall, Eye, sent a seedling Melon Thornham Hero, apparently a scarlet-fleshed Hero of Loekinge. The season being too late for judging Melons satisfactorily, the Committee desired that this promising variety be sent in the summer. Mr. Owen Thomas sent a seedling Melon Frogmore Late, white fleshed, sweet, and very juicy. The fruit had passed its best condition, though the rind was firm, and no award was made. Mr. A. G. White, Bow

Hill, near Maidstone, sent a dish of his seedling Apple Bow Hill Pippin, fine fruits, resembling a Blenheim, but with a deep yellow ground, and a little of the character of King of the Pippins; an Apple of promise, and an award of merit was adjudged. Mr. R. Weller, Glenstal Gardens, Murroe, Co. Limerick, sent a very good dish of Ribston Pippin Apples, and a vote of thanks was accorded. Mr. G. Paul sent a seedling Apple Captain Sandars, raised from Dumelow's Seedling, fruits large but soft, ineipient decay having set in with some of them. No award. Mr. W. Crump sent dishes of a local Herefordshire Apple of the Codlin character, with the red flush of Hollandbury, known as "Captain Tom." Though good, it was not considered better than existing varieties.

Mr. G. R. Allis, Old Warden Gardens, Biggleswade, sent small bunches of ripe Gros Colman Grapes, grown against an open wall without protection, also a dish of ripe Tomatoes from self-sown seed, as indicative of the tropical character of the summer (vote of thanks.) Mr. John Basham, Fair Oak Gardens, Bassaleg, Monmouth, sent specimens of large green curled Savoy and a dwarf early Cabbage. Though good samples they were not considered sufficiently distinct to merit an award. Mr. Barron sent from Chiswick splendidly blanched samples of the white Batavian Endive, the true compact form; also samples of Vilmorin's Queen of Winter, taller, but not better, and a cultural commendation was accorded.

Extensive displays of produce, both fruit and vegetables, were arranged on the side tables. A considerable number of Apples were sent by the Government of Nova Scotia, and though some of the fruits were fine, and the whole bright and tender-looking, as if grown under glass, yet many were small and affected with fungus. The samples, as a whole, were not by any means equal to those exhibited by Mr. J. H. Goodacre as grown at Elvaston in Derbyshire—a feather in the good gardener's eap, who has now defeated a government. His collection eomprised about eighty dishes of Apples, some of them very fine indeed, and nearly all highly coloured, several appearing as if polished artificially. There were also about sixty dishes of excellent Pears, and a silver-gilt Banksian medal was recommended. A similar honour was granted for a remarkably fine display of forty-eight bunehes of Alieante and Gros Colman Grapes, and about sixty dishes of Apples and Pears, staged by Mr. S. Mortimer, Rowledge, Farnham, Messrs. T. Rivers and Son exhibited several dishes of magnificent Pears, and very fine Apples of leading varieties, and a silver Banksian medal was unanimously recommended.

An extraordinary display of Onions was made by Mr. H. Deverill, Banbury, in all the leading exhibition varieties that are associated with the name of the exhibitor. There must have been about a ton of bulbs, several of them of gigantic proportions, and weighing 2 lbs. to 3 lbs. each. They afforded striking evidence of what can be accomplished by high culture and well selected stocks. A silver-gilt Knightian medal was recommended for this remarkable collection.

Not less imposing, more varied, and altogether excellent was an exhibit of produce by Messrs. Sutton & Sons, Reading, which extended along one side of the Hall. The collection included an imposing pile of Sutton's Early Gem Carrot, fine well coloured clean roots all of the same size; plants of the Aretie Green and the Aretie Purple Kale, dwarf, sturdy, and hardy looking, and we are told they are as hardy as they look; wonderfully fine Sutton's Autumn Giant Cauliflower, some of immense size, yet several as close and white as could be desired; superb heads of Sutton's Magnum Bonum Cauliflower, not so large as the preceding but of the first quality; thick fleshy green pods of the Prizewinner Runner Bean with slate-coloured dark mottled seeds to show the distinctness of the variety; a pile of Sutton's Snowball Turnips, models of their kind; also a highly meritorious collection of Onions of the varieties so elearly described on page 362 last week. large, elean symmetrical bulbs were shown as grown for exhibition; also not less shapely samples produced under ordinary culture and selected for planting for seed production. For this extensive display a silver-gilt Knightian medal was unanimously recommended.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); the Rev. H. H. D'Ombrain, Messrs. J. Laing, R. Owen, H. Herbst, R. Dean, H. B. May, G. Stevens, R. B. Lowe, C. F. Bause, J. Jennings, C. J. Salter, J. D. Pawle, W. Bain, W. Furze, T. Baines, C. E. Pearson, W. H. Williams, J. Walker, J. T. Bennett Poë, H. Cannell, C. E. Shea and G. Paul.

A grand collection of Chrysanthemums was arranged by Messrs. Jas. Veitch & Sons, Chelsea, amongst the best of which were Col. W. B. Smith, Beauty of Exmouth, Mrs. Falconer Jameson, Bouquet des Dames, Viviand Morel, Louis Boehmer, and Miss Anna Hartzborn (silver Flora medal). Mr. Jennings, gardener to L. de Rothschild, Esq., Ascot, sent a basket of grandly flowered plants of Begonia Gloire de Lorraine (first-class certificate). Mr. C. Holden, 61, Warwick Road, Ealing, showed a large plant of Chrysanthemum Sœur Mélanie, upon which there were said to be 2000 buds and blooms (bronze Banksian medal). A fine collection of Crotons was exhibited by Messrs. B. S. Williams & Son, Upper Holloway, amongst which Warreni, Queen Victoria, Williamsi, mutabilis, and Princess of Wales were noticeable (silver Flora medal). Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, showed blooms of Anthuriums, including Laingi, Leodense, Andreanum sanguineum, Lindeni flora carmine (first-class certificate), Andreanum, and two white seedlings. Pentstemon antirrhoides was also staged by the same exhibitor. Messrs. J. Cheal & Sons, Lowfield

Nursery, Crawley, arranged a fine stand of Dahlias. The Cactus section were finely represented, amongst the best being Professor Baldwin, Crawley Gem, Duchess of York, Amphion, and Sir F. Montefiore (award of merit, see below). Single varieties were also well exhibited, especially Lady Whitchead, The Bride, Florrie Fisher, and Mrs. Parrott (award of merit, see below). The show and fancy section were also shown, some fine blooms being staged (silver-gilt Flora medal). Mr. Wm. Pearce, gardener to G. Loder, Esq., Floore House, Weedon, showed five very beautiful specimens of Davall: a fijiensis plumosus. Messrs. H. Cannell and Sons, Swanley, were well represented by magnificent single Begonias and Chrysanthemums. The latter included Wm. Seward, Mdme. Le Blanc, Mdme. Edouard Rey, International, and Eda Prass amongst others. For Cactus Dahlia Cannell's Brilliant an award of merit was accorded (see below). A bronze medal was recommended for the collection. Messrs. Keynes, Williams & Co., Salisbury, staged blooms of the single Cactus Dahlias. C. E. Shea, Esq., The Elms, Foots Cray, showed a small but highly creditable stand of Chrysanthemums, which included Sylphide, Miss Dulcie Schroeter, The Tribune (award of merit, see below), and Bouquet des Dames.

Messrs. Cutbush & Sons, Highgate, exhibited an attractive collection of Pernettyas, amongst the best of which were rosca, atro-sanguinea, alba, and macrocarpa (silver Banksian medal). Mr. T. S. Ware, Hale Farm Nurseries. Tottenham, N., arranged a charming group of Cactus Dahlias, in which Mrs. Vince, Duke of Clarence, Mrs. Hawkins, Baron Schröder, and Delicata were conspicuous (silver Flora medal). Mr. R. Owen, Maidenhead, showed some grand Chrysanthemums, amongst the most noteworthy of which were Herbert Fowler (award of merit, see below), Rose Wynne, Richard Dean, and Miss M. Simpkins (award of merit, see below). The same exhibitor also staged a collection of small-flowered Chrysanthemums. Mr. Geo. Stevens, St. John's Nurseries, Putncy, S.W., received an award of merit for Chrysanthemum Madame M. Ricaud (see below). Mr. W. Wells, Earlswood Nurseries, Red Hill, staged a creditable group of Chrysanthemums, amongst the best of which were Wm. Scward, Majestic, Sunflower, Avalanche, Puritan, Prince Alfred, and Cæsare Costa. Mcssrs. J. Laing & Son, Forest Hill, S.E., staged a grand group of miscellaneous plants, for which a silver Flora medal was recommended. Begonias, Chrysanthemnms, Palms, Crotons, and a few Orchids were particularly prominent (silver Flora medal). Mr. Anthony Waterer, Knaphill, Woking, had a collection of hardy shrubs (silver Flora medal).

ORCHID COMMITTEE.—Present: Harry J. Veitch, Esq. (in the chair); Messrs. Jas. O'Brien, H. M. Pollett, A. H. Smee, Thos. Statter, Jas. Douglas, Henry Williams, J. Jacques, S. Courtauld, T. B. Haywood, Ed. Hill, C. J. Lucas, and F. Sander.

Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, sent a large collection, comprising some very choice forms. Cattleyas were conspicuous in this contribution, especially C. labiata, C. Bowringiana, and the beautiful C. Harrisi. Some charming bigeneric hybrids, including Lælio-cattleya Eumæa, L.-c. Cassiope, L.-c. pisandra (first-class certificate) were also shown by Messrs. Veitch & Sons, as were several excellent hybrid Cypripediums, including C. Clonius, for which a firstclass certificate was awarded (silver-gilt Flora medal). Messrs. Hugh Low & Co., Clapton, had a well arranged group of Cattleyas, Odontoglossums, and Cypripediums, which made a fine display (silver Banksian medal). The same may be said of the large collection of Cattleya labiata in variety staged by Messrs. Charlesworth, Shuttleworth & Co., Heaton, Bradford. These plants were large and remarkably well flowcred. The same firm exhibited the new Cypripedium Charlesworthi, which was certificated a few weeks ago (silver-gilt Banksian medal). G. F. Poeton Essa, Bishopsford, Mitchem and the Banksian medal). G. F. Poston, Esq., Bishopsford, Mitcham, sent two Cattleyas; and W. M. Appleton, Esq., Weston-super-Mare, had some fine Cattleyas, Olontoglossums, and Cypripediums. Awards of merit were adjudged for Cattleya labiata and Dendrobium Phalænopsis

Messrs. F. Sander & Co., St Albans, had a bright group of Cattleyas and other Orchids, including a splendid form of Dendrobium Phalænopsis Schröderianum. First-class certificates were awarded for Cattleya labiata var. Sanderiana, and C. Lord Rothschild, magnificent varieties, which are described elsewhere (a silver Flora medal was recommended for the group.) G. D. Owen, Esq., Selwood, Rotherham (gardener, Mr. Mark Watts), secured an award of merit for Cattleya Hardyana, Selwood var. This is described clscwhere. The same exhibitor had Cattleya labiata alba. Messrs. Heath & Sons, Cheltenham, sent some Cypripediums, including a good form named C. insigne albens (award of merit.) W. C. Clarke, Esq., Sefton Park, Liverpool (gardener, Mr. T. Jones), secured an award of merit for Cypripedium insigne Clarkei, a description of which will be found below.

Messrs. Linden, L'Horticulture Internationale, Brussels, sent a number of choice species and varieties, and awards of merit were adjudged for Cattleya Warocqueana Imschootiana and Paphinia grandis var. gigas. Description of these will be found below. Botanical certificates were also awarded for Dendrobium lamellatum and Pholidota convallarioides. Mr. H. Little, The Barons, Twickenham, sent a number of Cypripediums, and Sir Trevor Lawrence, Bart., had Cypripedium conco-Lawre and Cirropetalum amatissimum, for which a first-class certificate was awarded. Messrs. Lewis & Co., Southgate, N., sent a brightly coloured group, composed principally of Cattleyas and Lælias, and for which a silver Banksian medal was recommended. Mr. T. Statter, Stand Hall, Manchester, secured a first-class certificate for Cypripedium Statterianum, which is described elsewhere.

CERTIFICATES AND AWARDS OF MERIT.

Anthurium Lindeni flora carmine (Sir T. Lawrence).—This has very large spathes of a carmine colour (first-class certificate).

Begonia Gloire de Lorraine (L. de Rothschild, Esq.).—A beautiful variety of compact habit, and bearing masses of bright pink flowers (first-class certificate).

Cattleya labiata (W. M. Appleton, Esq.).—A splendid form of this favourite Orchid. The sepals and petals are of a rosy hue, the lip purplish crimson with a well defined white margin (award of merit).

Cattleya labiata var. Sanderiana (F. Sander & Co.).—This is a very fine form, being much darker than C. labiata Sanderæ. The sepals and petals are deep rosy mauve, the lip purplish crimson with a distinct white margin (first-class certificate).

Cattleya Hardyana Selwood var. (G. D. Owen, Esq.) -A fine variety with large flowers of an attractive character. The sepals and petals are rosy mauve veined white, the lip being rich maroon with a yellow blotch on each side of the throat (award of merit).

Cattleya Lord Rothschild (F. Sander & Co.) — This is a magnificent new hybrid. It is a cross between C. Gaskelliana and C. aurea. The sepals and petals are pale rosy mauve, the lip being the most striking feature in the flower. This is large, of a rich purplish crimson, with a crimped white margin, the throat and basal portion being orange yellow

veined white and rosy magenta (first-class certificate).

Cattleya Waroequeana Imschootiana (Linden, Brussels).—A beautiful flower, with large petals and sepals of a bright purplish rose shade. The centre of the lip is rich crimson, the edging being fimbrated,

pale margin (award of merit).

Chrysanthemum Ryecroft Glory (H. Cannell & Sons).—A charming reflexed variety, with medium sized flowers of a rich yellow colour. A useful decorative Chrysanthemum (award of merit).

Chrysanthemum W. H. Fowler (R. Owen).—This is a Japanese with straight yellow coloured petals of perfect form (award of merit).

Chrysanthemum Miss M. Simpkins (R. Owen) .- A pure white incurved Japanese of great substance and superb shape (award of merit).

Chrysanthemum Madame M. Ricaud (G. Stevens).—A melium sized flower of a deep rose pink colour (award of merit).

Chrysanthemum The Tribune (C. E. Shea and H. J. Jones).—A broad petalled, lemon-yellow coloured Japanese variety of grand form (award of merit).

Cirropetalum amatissmum (Sir T. Lawrence).—A curious looking flower of a dull brownish colour, the lip being reddish brown (first-class certificate).

Cypripedium Clonius (J. Veitch & Sons).—This is an exceedingly interesting hybrid of a chaste colour. It is the result of a cross between C. caudatum Lindoni and C. conchiferum. The dorsal sepal is long and pointed, as are the petals, with tail-like appendages; both sepal and petals are white, veined green, the lip also being white, spotted brown (first-class certificate).

Cypripedium Statterianum (T. Statter, Esq.).—This is a richly coloured Cypripedium. It is the result of a cross between C. Spicerianum magnificum and C. vexillarium superbum. The dorsal sepal is rose coloured with a white margin, the petals and lip being brown (first-class certificate).

Cypripedium insigne albens (Heath & Son).—A distinct form with a well defined white tip on the dorsal sepal. The lip and petals resemble those of the type (award of merit).

Cypripedium insigne Clarkei (W. C. Clarke).—This is a good form of the well known type. The dorsal sepal is very distinct, having a broad white margio. The lip and petals are similar to those of C. insigne (award of merit).

Dahlia, Cannell's Brilliant (H. Cannell & Sons).—A rich velvety crimson coloured Cactus variety with a deeper centre (award of merit).

Dahlia Sir F. Montefiore (J. Cheal & Son).—This is a very grandly formed Cactus flower of a rich velvety maroon shade (award of merit).

Dahlia Mrs. Parrott (J. Cheal & Son).—A small single flowered variety having white and red petals (award of merit).

Dendrobium Phalænopsis, Appleton's var. (W. M. Appleton, Esq.).

—The lower part of the sepals and petals are white, the lips being rosy magenta, the lip similarly coloured (award of merit).

Lælio-Cattleya Pisandra (J. Veitch & Sons).—The sepals and petals of this charming begeneric hybrid are pale rosy mauve, the lip being a very rich maroon with yellow in the throat (first-class certificate).

Paphinia grandis var. gigas (Linden, Brussels).—The flower of this is larger than the type. It is tipped and spotted with reddish brown, the centre being white (award of merit).

LECTURE ON ONIONS.

Mr. A. Dean, after tendering to the exhibitors of Onions at the meeting grateful thanks for the effective illustration of the subject of his paper that day, dealt with the various forms or species of Alliums in cultivation, including Onions proper, Leeks, Shallots, Potato Onions, and Tree Onions, and then referred to the Union trial conducted at Chiswick. describing its character, and the reasons for the awards made by the Fruit Committee in connection with the trial, defending the action as against some criticism in the press and else-Then came descriptions of the diverse forms into which Onions are divided, white, yellow, brown, and red of colour, and of flat, round, and globular in shape. Special emphasis was laid on the fact that keeping properties in the Onion seem to be least in the white-skinned section, and best in the red Onions, also that the deep globular forms invariably kept better than did the flat bulbs, and asked what were the causes that led to such results. The present size to which exhibition Onions are grown came in for strong and adverse criticism, the lecturer holding that they served no good purpose, did not keep well, and were not profitable to grow.

The method of growing them was also described, and the names of the chief bulb producers mentioned. Some stress was laid on the profit-

AGLAONEMA ROTUNDUM.

As will be seen by referring to the illustration (fig. 56) this is a charming ornamental foliage plant. It is of a dwarf habit, and is suitable for growing in pots or pans in a stove. The leaves are oblong ovate, from 4 to 5 inches in length, and about 3 inches in breadth. On the upper surface they are rich green blotched with silvery grey, which deepens as the foliage matures. The under surface is pale green. The

FIG. 56.—AGLAONEMA ROTUNDUM.

able nature of the Onion as an ordinary crop, and one instance was given showing that from 600 to 800 bushels of fine bulbs per aere had resulted. Mention was also made as to the nature of the Onion as an edible vegetable, some quotations in respect to best forms of cooking being made from the Messrs. Sutton & Sons' valuable little book, the "Art of Preparing Vegetables for the Table," and it was pointed out that diverse as were the uses of the Onion, under no circumstances were bulbs more valuable as food than when properly boiled or baked.

plant, from a sketch of which the engraving has been prepared, was exhibited at the Drill Hall, Westminster, on Tuesday, September 26th, by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, when the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for it. This Aglaonema will form a fitting companion to A. costatum, which was illustrated and described in the Journal of Horticulture for August 18th, 1892.

WE have received numerous intimations of Chrysanthemum shows which are to be held during the next few weeks, but space can only be found for the enumeration of those that have heen advertised in our columns up to date, of which the following is a list:-

Oct. 31st and Nov. 1st and 2nd.—Portsmouth.

Nov. 1st and 2nd.—Kent County (Blackheath).

" 3rd and 4th.—Crystal Palace.

" 7th and 8th.—National Chrysanthemum Society (Royal Aquarium), Kingston, Liverpool, Leeds Paxton, Brighton, Watford. 8th and 9th.—Northampton, Bournemouth.

9th.—Birkenhead and Wirrall.

", 10th and 11th.—Bradford.
", 11th and 12th.—Ascot.
", 14th and 15th.—Twickenham, West of England (Plymouth).
", 15th and 16th.—Birmingham, Hull, Bristol, South Shields, Rugby.

", 15th, 16th, and 17th.—Herefordshire.
", 16th, 17th, and 18th.—Scotland (Edinburgh).

,, 24th and 25th.—Eccles and Patricroft.

INNER TEMPLE GARDENS.

THE annual Exhibition of Chrysanthemums grown in the Temple Gardens is now open and the plants on the whole make a good display. They are arranged in the glass house that was erected last year in the eastern corner of the gardens. Mr. John Newton, who for twenty-four years has filled the post of head gardener to the Benchers of the Inner Temple, has brought together an excellent show, equal in all respects to its predecessors. The plants, which are vigorous and healthy, represent all the best known varieties and include many new acquisitions. Among the latter is noticeable Enfant des Deux Mondes, a white Louis Boehmer, a large and finely developed descendant of this striking specimen of the so-called hairy section. Another charming variety is Charles Davis, a grand yellow flower of Viviand Morel parentage. Miss Minnie Newton is a bloom of beautiful shape, golden bronze colour. Another successful sport is the Mr. Charles E. Shea.

Among the other novelties are Colonel W. B. Smith, an old gold colour, and the Papa Toussaint, a golden red and dark ochre yellow both of which are in early stages yet, but promise to be fine specimens. Cæsare Costa is also well represented, and the Sylphide, a light chrome yellow, is deepening its tint almost to orange. Among the older varieties F. R. Davis, with its long, delicate crimson petals, Sunflower, E. Molyneux, Gloire de Rocher, Louis Boehmer, J. Stanborough Dibbens, and others are showing remarkably well. Comparatively few incurved varieties are as yet expanded, and, therefore, intending visitors who take the most interest in this section, may advantageously defer their visit for a week or ten days, by which time the flowers will be at their best.

The exhibition remains open for six weeks.

BATTERSEA PARK.

THE Show of Chrysanthemums arranged at this Park is in every way a praiseworthy one. The plants are admirably grown, and are palpable evidences of skilful management and unremitting attention. There are upwards of 2000 plants on show, and they make a grand display. Not only is improvement manifested in the column in the column is improvement. play. Not only is improvement manifested in the plants, but likewise in the structure and the arrangement. Last season the house was divided by a partition in the centre, which detracted greatly from the general effect. This partition Mr. Coppin, the Superintendent, has now removed, and the plants are arranged on each side of the house with a path in the Notwithstanding the manifest improvements in the existing house, and that better advantage has been taken of the space at disposal, the accommodation is still inadequate, and we can but surmise what a magnificent display would be provided if Mr. Coppin had such a place as the Albert Palace at his disposal. We can readily imagine what the results would be if the Palace could be added to the Park and put in the charge of the present Superintendent. In connection with the Chrysanthemums the name of Mr. Tilbury must be mentioned, for the Exhibition is to a large extent the result of his industry.

Regarding the individual plants we can find nothing for them but praise, and they are in every way worthy of it, for they are thoroughly grown, and carry grand flowers. It is yet early to form a final idea of what the exhibition will be, as many hundreds of blooms have yet to open. In another ten days the Show will be at its hest. At the present time the finest varieties in flower include Edwin Molyneux, of which there are some superb examples; Florence Davis, Avalanche, Lady Selborne, Gloire du Rocher, William Seward, very fine; Mdlle. Elise Dordan, Charlotte de Montcabrier, Gloire Rayonnante, Stanstead Surprise, Edouard Audiguier, Mons. William Holmes, Sunflower, Mr. Bunn, Golden George Glenny, Jeanne d'Arc, and Georgeous amongst numerous others. We are glad to know that the Show gains yearly in popularity, and have no doubt that during the weeks that it remains open it will be patronised by many thousands of people who take an interest in the

plants under their notice.

DULWICH PARK.

ALTHOUGH Mr. Moorman, the able Superintendent of this beautiful park, had no structure in which to show Chrysanthemums during the autumn months, he has grown upwards of 600 plants; these are now coming into bloom, and they are a credit both to the grower and to the County Council. Mr. Moorman is evidently a man of resource, and as he had no proper house he has succeeded with the aid of pitlights, mats, strong cord, and stout quartering in erecting a makeshift structure. Let us hope that such determination to give the inhabitants of the surrounding district a look at the "Autumn Queen" will not pass unrewarded, and that ere another season the authorities, who are ever ready to cater for the wants of the public, will have erected a good house, and such being done we should expect to find as excellent a display at Dulwich as is now to be found at many of the other metropolitan parks.

That they can be grown as well there is ample evidence by those now coming into bloom. Large flowers have not been the aim, but a goodly number, and the plants are now carrying clean buds and a few blooms on strong healthy plants which have grand foliage, and that almost to the pots. Amongst the varieties now in bloom are Bouquet des Dames, very good; Florence Davis promises well, as do Viviand Morel,

Avalanche, and many others.

Out of doors the summer flowering section is grandly represented, the plants forming bright and beautiful masses of colour. The well known Piercy's Seedling is magnificent, Flora is one of the most conspicuous, Mrs. Hawkins is a pleasing yellow coloured variety, Mdlle. Leoni Lassali is a grand white, and Mignon is a useful bright yellow coloured dwarf variety. These plants are deserving of more attention than is at present accorded to them, and they will doubtless grow in favour as some of the improved kinds become known.

SOUTHWARK PARK.

An improvement since last year is manifest in the structure for the Chrysanthemums at this park, a large wing having been built on to the existing house, and well has Mr. Bailey taken advantage of the additional space placed at his disposal. The plants shown number upwards of 2500, and all are in an excellent condition. stout, deep green in colour, and the blooms substantial and decidedly above the medium size. The arrangement, too, is admirable, the plants being staged in such a manner as to allow the best points of the flowers to he seen at a glance. The colours are well diversified, and great care has evidently been given to placing the plants so that the colours should not clash. The collection is a highly creditable one, and great credit is due to Mr. Bailey for his success in growing such a grand display. Thousands of people are visiting the Show, and many are the expressions of admiration accorded, and very deservedly so, to the beauty of the flowers. In the densely populated district in which this park is situated there are many who delight in such a display of Chrysanthemums, and all praise is due to the County Council for the manner which

they look to the wants and desires of the people of London.

It would be impossible to name all the varieties staged, they are far too numerous, and as all are good the task of making a selection is somewhat difficult, as so much depends on individual taste; however, all will doubtless appreciate the magnificent blooms of Condor and the brightly coloured Gloire du Rocher. Not less beautiful are James Salter, of which there are many exceptionally fine blooms; Refulgens, Jeanne d'Arc, both very fine, as also is the popular H. Shoesmith. Here, as appears to he the case in many collections this season, Edwin Molyneux is grand, the blooms being massive, and the colouration perfect. Amongst the yellows Peter the Great must be accorded a prominent place, closely followed by Gorgeous and Gloria Mundi. The chaste Elaine is admirably represented, many of the blooms being of a high order of merit; and the same may safely be said of Puritan. Hairy petalled varieties are in a minority, Louis Boehmer being the only one noticeable, but this was fine, quality amply filling the place of quantity. Several plants of Lady Selborne are carrying grand examples. Val d'Andorre promises well, as also does Cæsar Costa. The blooms of Charlotte de Montcabrier are very perfect on many of the plants, and Mons. Wm. Holmes must be included amongst the best. Stanstead Surprise, George Gordon, C. Orchard, Mons. Astorg, Leopard amongst numerous others were very fine, and with these we must close our list.

WATERLOW PARK.

THE Chrysanthemums in Waterlow Park, Highgate, are decidedly better than they were last year, and Mr. R. Curle, the Superintendent, may be congratulated on the collection he has brought together. The plants are well grown and the buds are now fast expanding, the earlier Japanese varieties being this week at their best. Most of the plants are arranged in a small conservatory, a circular group occupying the centre, whilst others are placed on each side. Amongst these are some excellent blooms of the choicer sorts, which cannot fail to interest the numerous visitors. Some new varieties are grown, the best of these heing William Seward, J. Shrimpton, and Beauty of Exmouth. last named is developing some magnificent blooms, which will justify all that has been said in favour of this variety. Bouquet des Dames is showing remarkably well, and the same may be said of Viviand Morel. Mons. W. Holmes is in excellent character, the brilliant blooms showing up conspicuously amougst others less brightly coloured. Some grand buds of William Tricker are noticeable, and Stanstead White will be seen in splendid condition shortly. Margot is carrying some fine blooms, and the same applies to Miss A. Hartshorn. Such well-known and useful varieties as Madame de Seven, La Triomphant, Mons. Tarin, and Sunflower arc also well represented and make a conspicuous display. That charming white variety Avalanche is expanding some excellent blooms of great substance, and the striking yellow Japanese Gorgeus is making a fine show.

The incurved varieties are not yet very conspicuous, but some are grown. A few good blooms of Mons. R. Bahuant were noticeable, and some plants of Mrs. G. Rundle were developing fine flowers. In addition to the Chrysanthemums arranged in the conservatory there are others in three vineries, there being about 2000 plants grown. Grapes are hanging on the Vines, and on the front stages flowering and foliaged plants are arranged, these adding further interest to the collection. On the whole the display is a good one, and well worthy of a visit during the next few weeks.

FINSBURY PARK.

For producing a display of Chrysanthemums Finsbury Park has long been famous, but since the crection of a commodious structure for this purpose by the London County Council, a few months ago, it is likely to become even more noted in that respect. At all events this fine building, which is lafty and upwards of 80 fect in length by about 25 feet wide, is a decided improvement on the low house in which the plants were formerly staged. The Chrysanthemums may now be viewed with pleasure, and the thousands of visitors who will pass through the house daily during the next few weeks may do so without any discomfort. The provision of this splendid structure is a commendable act, and, it is hoped, one which will be extended to the other parks.

The house in question is situated near the Manor House entrance to the park. There being plenty of room the plants are not so crowded as are necessary in many instances, and this is an advantage so far as displaying the habit of each plant is concerned. There are, of course, some rather tall plants at Finsbury Park, but the majority of them are comparatively dwarf, which enhances their appearance. All the standard varieties are grown, and are now rapidly developing some fine blooms. Mdlle. Marie Hoste, one of the finest whites in cultivation, is promising well, and the same may be said of Bouquet des Dames. The old Elaine is good and some fine blooms of Viviand Morel and Mons. Tarin are noticeable. Edwin Molyneux shows up conspicuously, as also do Criterion, Mons. Freeman, Cæsar Coste and Mr. C. E. Shea, the last named being very fine. An Anemone flowered variety named Deleware is obviously well grown here, as are some of the Pompon type. The incurved varieties are not yet at their best, but some fine buds of Mons. R. Bahuant, Golden Beverley and Comte de Germiny are developing. These varieties and others will have grand flowers on them a week or ten days hence.

As before remarked the plants are well grown, and the collection as a whole reflects credit upon Mr. Melville, the Superintendent, whose efforts in this direction are much appreciated by the residents of northern suburbs of London.

THE PRIORY, HORNSEY.

In no private garden in the suburbs of the metropolis are Chrysan-anthemums better grown than they are at The Priory, Hornsey. Here Mr. E. Rowbottom, gardener to H. R. Williams, Esq., a gentleman well known in horticultural circles on account of the interest he has displayed in helping forward the fruit-growing industry, has for the past three or four years produced some of the finest blooms that have ever been exhibited, and this year apparently will prove no exception to the rule now established. Skilful culture has left its mark, and it is safe to prognosticate that Mr. Rowbottom will be well represented at the leading exhibitions during the next few weeks. Last year he secured a 10-guinea cup as his own, in addition to silver medals, and it is very probable that this Horcsey grower will this season take a place amongst the first rank of exhibitors.

When a Journal representative made a call last week he found Mr. Rowbottom busily engaged amongst his favourite plants. These are exceedingly well grown, and are now fast developing remarkably fine blooms, especially the Japanese type. All the newer varieties are grown, and many of these are likely to prove charming acquisitions. Mullc. Thérèse Rey, which is, perhaps, one of the finest creamy white varieties now in cultivation, is showing splendidly, and no doubt will be seen on the exhibition boards shortly. A certificate was granted for the variety recently. A new Japanese variety named Edith Rowbottom is likewise very fine, the blooms being large, well built, and of great substance. This is a seedling raised by Mr. Rowbottom, and a certificate was awarded for it at the Royal Aquarium the other week. President Borel, for which Mr. Rowbottom has also gained a certificate this year, is remarkable for its size and striking appearance. It has long purple florets with a golden reverse. Kentish Yellow is grand, being massive in build, and yet of a graceful appearance. Golden Dragon is in prime condition, and the same applies to Primrose League, a pale yellow variety. Eda Prass, an American seedling of the Japanese type, and for which a certificate was granted recently, is also well represented at The Priory, and apparently Mr. Rowbottom will repeat his success of last year with Mdlle. Marie Hoste, inasmuch as some enormous blooms of that charming variety are fast developing. The white Louis Boehmer is excellent, and G. W. Childs will prove good. The favourite Col. W. B. Smith is in grand condition, as also are numerous other choice varieties. Mr. Rowbottom is likewise growing many seedlings of merit, about which something will be heard later on.

The incurved varieties form a feature at The Priory, although another week must elapse before these are seen at their best. The buds,

however, have been well timed, and at the forthcoming exhibitions many grand flowers will be seen. Some splendid flowers of Madame Darrier arc noticeable, and Mrs. Brunlees is very fine. Mrs. Robinson King, Lord Alcester, and John Lambert are likely to develop blooms of extraordinary size and substance, and a good character is given the new Vice-President Jules Barigney. Although rather a tall grower, this is likely to prove a useful incurved variety for exhibition. The flower is large, similar to Lord Wolseley in build, and pale buff in colour. Another new incurved, named Miss Bella Wilson, is splendid, and Mrs. G. Rundle is exceedingly well grown at The Priory Gardens. Other good incurves are Baron Hirch, Violet Tomlin, Mrs. Shipman, and Miss Haggas. Many more varieties are deserving of mention as being particularly fine, but space is limited, and for the present a brief reference must suffice.

CHRYSANTHEMUMS AROUND BOURNEMOUTH.

HAVING spare time, and being much interested in Chrysanthemums, I made a trip to Bournemouth to see how the plants were looking in that locality, and thinking that remarks on our favourite autumn flower will interest your readers, I send you a short account of my excursion.

CRANMOOR LODGE.

I paid my first visit to Cranmoor Lodge, the seat of Mrs. S. Elphinstone, where I was courteously received by Mr. J. W. Taylor, the head gardener. The Chrysanthemums are arranged in sections in the Peach houses and vineries. The plants range from about $4\frac{1}{2}$ fect to 7 fect in height, and carry excellent foliage from the bottom. The more notable blooms now showing are Mons. R. Bahuant, A. Salter, Golden Empress, Mrs. R. King, J. Salter, Mr. Brunlees, J. Lambert, and the Teck family. Most noticeable amongst the Japanese were Beauty of Exmouth (the coming flower of the season), Golden Dragon, Louise Boehmer, Mrs. C. Wheeler, Mrs. F. Jameson, J. S. Dibbins, Mrs. E. D. Adams, W. Seward, the new Golden Viviand Morel (Beauty of Castlehill), which should develop into a magnificent bloom. Mr. Taylor has several new varieties with promising buds. There are about 350 plants for exhibition blooms and the same number of cut-back plants for conservatory decoration. Mr. Taylor won the cup in the cut bloom competition at the Bournemouth Chrysanthemum Show last season, and if the plants go on as they promise he will be a formidable competitor this season. The gardens are admirably managed throughout.

THE NEW ROYAL NURSERIES.

I next called upon Mr. Ratsch at the new Royal Nurseries, where he has erected sixteen houses each 50 feet in length. Some are filled with Chrysanthemums, mostly cut-backs. I noticed Lady Selborne, Source d'Or, Buttercup, Ethel, and Lady Lawrence are extensively grown. There are altogether about 5000 plants in excellent condition. Other houses are filled with Carnations and winter-flowering plants, and there are two houses of the Chemin Rouge Tomato which are showing a fine crop. Both houses and grounds show signs of good attention, and visitors to Bournemouth will do well to call at these nurseries.

PALACE NURSERY.

Messrs. Watts & Sons have now about 7000 Chrysanthemums arranged in their fine conservatory. The plants are grown in 10-inch pots, and include all the leading varieties. Decorative plants are grown in large numbers, in one house there are 1500 Tea Roses. Messrs. Watts have given up growing Chrysanthemums for exhibition. They have been very successful, winning four silver cups in the open class for groups at the Bournemouth Show. The nurseries at Heath Farm and Ensbury cover about 60 acres, and are well stocked. I recommend any gardener or other person interested in horticulture of paying a visit to Bournemouth to avail themselves of the opportunity of calling on the gentlemen named.—A GARDENER.

CHRYSANTHEMUMS AROUND LIVERPOOL.

At The Hollies, Woolton, Mr. Vaughan has this year over 250 plants, the greater portion of them being in excellent condition. In the Japanese Etoile de Lyon, Florence Davis, W. Tricker, Bouquet des Dames, Stanstead White, Mdlle. Marie Hoste, W. H. Lincoln, Mrs. F. Jameson, Mons. Bernard, E. Molyneux, and Col. W. B. Smith are amongst the best. In the incurved the Queens, John Salter, Empress of India, Lord Wolseley, Jeanne d'Arc, Ami Hoste, and Madame Darrier are all good. Mr. Vaughan has lost a great number of buds owing to the plague of caterpillars.

HIGHFIELD, WOOLTON.

Mr. Haigh, gardener to W. H. Tate, Esq., grows about 600 plants, and I never saw them look so promising. His best incurved are Empress of India, Mons. R. Bahuant, Jeanne d'Arc, Madame Darrier, all the Princess family, and new Baron Hirsch. The Japanese are particularly fine, the best Lilian B. Bird, Florence Davis, Gloire du Rocher, Puritan, Mrs. F. Jameson (grand), W. Tricker, A. H. Nevc, Stanstead White, Sunflower, and in the new section Mrs. C. H. Payne, Lord Brooke, J. Shrimpton, W. Seward, Col. W. B. Smith, Mrs. Nisbet, and Chas. Davis, the grand bronzy yellow sport from Viviand Morel.

ALLERTON HOUSE, ALLERTON.

Mr. George Eaton ought this year to be heard of if his collection of plants is a criterion. The Japanese opening very freely include Boule d'Or, Viviand Morrel, Mrs. F. Jameson, W. H. Lincoln, G. C. Schwabe,

W. Tricker, Florence Davis, and of new ones Chas. Blick, Col. Smith, W. Seward, J. Shrimpton, Beauty of Exmouth, Lord Brooke, Mrs. C. H. Payne, and Chas. Davis. The incurved are also most promising, and include Queens, Princess, and sports, Mons. R. Bahuant, Jeanne d'Arc, Madame Darrier, Baron Hirsch, Ami Hoste, and Madame E. Mintrel. F. Mistral.

ALLERTON BEECHES.

There are about 340 plants grown here, and Mr. Edwards will doubtless give a good account of himself this season. The plants are dwarf and healthy. The incurved are likely to produce good flowers, the Princess family, Baron Hirsch (grand), Lucy Kendall, and Vice-President Jules Barigny being very good. The Japanese are splendid, the best being Stanstead White (superb), Mrs. F. Jameson, Mrs. Irving Clarke, E. Molyneux, G. C. Schwabe, the newer ones being Chas. Davis (grand), Lord Brooke, Beauty of Exmouth, Alcazar, Majestic, W. Seward, John Shrimpton, Kentish Yellow, Miss Watson, Mrs. Hubback, Viscountess Hambledon, Col. W. B. Smith, and Primrose League.

DOVE PARK, WOOLTON.

Mr. Carling has 300 or 400 plants, the finest being Viviand Morel, Mrs. F. Jameson, La Verseau, E. Molyneux, W. H. Lincoln, Florence Davis, W. Tricker, Mdlle. Marie Hoste, and Mons. Bernard: and in the newer section Charles Davis, Colonel W. B. Smith, Princess May, Princess Victoria, G. W. Childs, Ruth Cleveland, W. Seward, J. Shrimpton, Lord Brooke, and Beauty of Castlewood. Incurved varieties include Princess and Queen families, also Jardin des Plantes, Lord Wolseley, Baron Hirsch, Alfred Lyne, a useful sport from Novelty; and Madame Frederic

CAMP HILL, WOOLTON.

Mr. Jellicoe has grown about 600 plants. The Japanese are strong, and give great promise of superh flowers. The best are Bouquet des Dames, Mrs. F. Jameson, W. Tricker, Etoile de Lyon, Gloire du Rocher, Viviand Morel, Puritan, Mrs. E. W. Clarke, Florence Davis, W. K. Woodcock; and of the newer ones Robert Owen, Ruth Cleveland, Mrs. C. H. Payne, Princess May, G. C. Schwabe, Lily Measures, Mr. G. Herring, J. Shrimpton, Mrs. E. D. Adams, Beauty of Exmouth, William School and Challes Hubback. Seward, and Charles Hubback. Amongst the incurved thirty plants of Mons. R. Bahuant in different stages are conspicuous. Baron Hirsch is also well grown, the blooms being large and massive. The Queen and Princess types are all with good clean buds. Amie Hoste, Madame Darrier, Jeanne d'Arc, and Madame F. Mistral are fine.

Mr. Jellicoc had pieces of clean white tiffany stretched about 1 foot from the roof over all his best blooms. He fully believes that damping is prevented by doing this, and I can fully bear him out, for there was not a decayed pe'al. Those not covered damp badly.

HILLSIDE, ALLERTON.

Three hundred plants are grown here, and very promising they look but are rather late. Queens and Princess types are fine, particularly the but are rather late. Queens and Frincess types are line, particularly the latter. Hero of Stoke Newington is very good. The best Japanese are W. Tricker, Gloire du Rocher, Puritan, Mrs. F. Jameson, Mdlle. Marie Hoste, Felix Cassogneau, J. T. Kendall, Beauty of Exmouth, and Le Verseau. If Mr. Healey can get his best blooms out he will be hard to beat. I noticed here a fine reflexed variety named Mr. M. Sullivan.

ELM HALL, WAVERTREE.

Mr. J. Bracegirdle grows 350 plants. The best incurved arc Princess of Wales, Mrs. Coleman, Mrs. Heale, and Miss Haggas all rightly timed; Alf. Salter, John Lambert, and Mons. R. Bahuant are certain to turn out well. I fear he will be a little weak in the Japanese as regards numbers, but substantial buds unfolding were Lilian B. Bird, Mrs. F. Jameson, Boule d'Or, Florence Davis, Puritan, G. C. Schwabe (extra), W. Tricker, Etoile de Lyon, Viviand Morel, Mrs. J. Clarke, Mrs. J. S. Dihhen, E. Molyneux, and Col. W. B. Smith. Reflexed were the most likely to pull him up a great deal, being extra

Mossley House, Mossley Hill.

Mr. Heaney here grows 300 plants, most of them being dwarf, and carrying grand massive huds. The Japanese particularly fine are Mrs. F. Jameson, Mrs. E. W. Clarke, Mrs. C. H. Payne (splendid), Miss Anna Hartshorn, Florence Davis, Boule d'Or, W. Tricker, G. C. Schwabe, Viviand Morel, W. Seward, J. Shrimpton, La Verseau, Harry May, Princess May, Chas. Blick, Puritan, Louis Boehmer, Col. W. B. Smith, Chas. Davis, J. Stanborough Dibben (extra good), Silver King, and Robert Owen. The incurved are just as good; Queens and Princess types fine, as also were Madame F. Mistral, Madame Darrier, Mons. R. Bahuant, Jeanne d'Arc, and Baron Hirch.

CALDERSTONES.

Although not an exhibitor now, Mr. Tunnington's work is always worthy of a note. This year he has the finest of plants and not so early as many supposed they would be. He is the same opinion as others, that the early buds of the Queen family will he very coarse, and it will be from terminal buds that the best exhibition flowers will be produced. The older varieties of incurved and Japanesc are looking well. Baron Hirsch is splendid, and praised by all who see it. He thinks it will have to be grown on terminal buds for show purposes, owing to its being inclined to come early. Lucy Kendall is a good yellow sport from Mrs. Heale, but he fears confusion with it and Miss Haggas. In Japanese Eda Prass is proving a good variety. Waban on early buds forms "hen and chicken" flowers; but late buds are opening well, as is also Beauty

of Exmouth, the same remark applying to William Seward. C. B. Withnal is very promising. J. T. Kendall and R. C. Kingston are showing remarkably fine flowers; and Mrs. A. Jacobs, a yellow sport from Madame Baco, promises well. Mr. Tunnington shares exactly the same opinion as Mr. Jellicoe regarding the vexed question of damping, believing that tiffany spread over the opening buds will prevent it, for on a damp morning the tiffany may be seen hanging with beads of damp, which would otherwise fall upon the flowers.—R. P. R.

NOTES ON PRIZE SCHEDULES.

AT the time of writing I have before me a list of ninety Chrysanthemum Exhibitions to be held within the space of exactly four weeks, commencing with Havant, October 27th, and finishing with Eccles November 24th. As some readers have not an opportunity of inspecting the schedules of prizes of the various meetings I purpose making a brief reference to the manner of offering the principal awards at what are termed the leading Shows.

As before remarked, Havant opens the Exhibition season on October 27th. Portsmouth follows next on the 31st, this Exhibition heing held in one of the finest halls in the kingdom. The prizes offered for competition are excellent, and some magnificent blooms are usually seen at Portsmouth. The principal class is that for forty-eight cut blooms, half Japanese and the remainder incurved, eighteen varieties being required in each section. Prizes of £10, £7, £5, and £3 are offered. As much as £5 for first is offered for twenty-four blooms in another class. Chrysanthemums in pots, both trained and in groups,

receive liberal encouragement also.

Kent County Show, held in the Rink at Blackheath on November 1st, is considered one of the best of the London Exhibitions. £10 are offered as first prize for best thirty-six blooms, half incurved and the remainder Japanese. Amateur classes are provided liberally, the prizes being quite adequate in every respect. On the same date the annual Exhibition is held in the Grand Stand at Ascot. In addition to cut blooms section groups of Chrysanthemums are here seen at their best. The cultivators in the neighbourhood make a special study of this system. On Friday, November 3rd, the Crystal Palace Show opens. As it does not clash with any other important meeting in the south it is certain to be well attended by southern exhibitors. As is usual, the prizes are substantial and the classes easily filled.

The succeeding week is a busy one; no less than eleven shows are held on Tuesday, November 7th, and the same number on the following day. Foremost comes the Exhibition of the National Chrysanthemum Society at the Royal Aquarium, Westminster. No less than forty-four classes are provided for cut blooms alone. As first prize the challenge trophy and £10 are offered as usual to horticultural societies for competition, and is certain to induce a spirited contest. The "Holmes" Memorial challenge cups are for incurved and Japanese blooms in separate classes. In addition £7 are added in each case for the premier award. No doubt the finest blooms available will be staged in these classes. Extremely handsome prizes are offered in many other classes. A silver cup and £4 for twenty-four distinct blooms in the Japanese section as first prize should induce a keen competition. The Exhibition at Kingston also opens on the same day. The interest here is increased by the fact of its being the final year for competition of the challenge vase offered in 1890, it having been won by three separate persons during that time. In addition a new vase is offered of the same value, 25 guineas, as the older one, which will provide attraction to visitors and exhibitors alike. For twenty-four varieties of incurved blooms a silver cup, value 5 guineas, along with the cash prize of £3, is offered. The conditions binding the competitors in the challenge vase classes are deserving of note. The whole forty-eight blooms are confined to the incurved and Japanese sections, but they must be distinct. Many societies allow duplicates to be employed in halt-a-dozen instances, but with such a rapidly increasing list of varieties these large classes ought The interest is carried northwards on the 9th to to be distinct. Birkenhead, on the 10th to Bradford and Derby, all of which can boast of successful meetings.

Exeter, on November 10th, deserves a mention. Some of the finest Japanese blooms in the south of England invariably find their way here. Batley, Bacup, and Crewe prefer Saturday exhibitions. In all of these districts Chrysanthemums are really well grown. Plymouth opens its Show for the second season on the 14th, and £33 are offered in one class for forty-eight blooms, £15 going to the first prizewinner. less than fifteen shows are set down for the following day, November 15th, including Bristol, Birmingham, Hull, Reading, York, and Winchester. The first-named place has long been famed for the trained plants. Birmingham is an important meeting. The prizes for incurved blooms are good; £10 is the sum for the premier award in twenty-four distinct varieties. Six prizes are offered in this particular class. The same conditions apply to the Japanese section. In other classes £3 is offered ditions apply to the Japanese section. In other classes £3 is offered for the best eighteen incurved blooms, and the same for Japanese.

At Hull the prizes are of the usual liberal character. For twenty-four incurved blooms £10 and a silver cup as well is offered for first prize (vide Journal of Horticulture, October 12th, page 339). In the premier Japanese class the prizes are the same as in the former. A new class is provided, with a view to introducing a fresh method of arranging Japanese blooms. A table space of 6 feet by 2 feet 6 inches is allowed to each competitor for the twenty-four Japanese blooms stipulated for. Plants have their share of patronage.

The Scottish Exhibition opens at Edinhurgh on November 16th, and handsome prizes are offered in the leading classes. Bolton, Stockport,

and Sheffield hold their meetings on November 17th, and liberal prizes are offered. Dundee and Ayr are set down for November 22nd. At the latter place a silver cup, value £20, is offered in addition to the money prize for eighteen Japanese blooms.—E. MOLYNEUX.

NEW SELF CARNATIONS.

(Continued from page 362.)

THIS section, although recognised by florists as exhibition flowers, having all the good qualities of the "Show" Carnation in exquisite form, size, breadth, and smoothness of petal and evenness of the edge, and are quite unlike to ordinary serrated-edged kinds one so often meets with, is always very much admired, for we have now many charming shades of colour, from pure white to the deepest crimson maroon, almost black. The exquisite shades of rosy pink and salmon, light carmine, rosy purple and deeper purple, and numcrous other charming blending of shades, makes this a most interesting class, and many of them are as richly perfumed as the old Clove Carnation. Rich as we had become in varieties, the season of 1893 added several more gems, and the following are amongst them.

Amor (Benary).—Bright rosy carmine, slightly flaked, a brilliant

handsome flower of fine quality.

Attraction (Chaundy).—Delicate soft pink, a large, bold flower, valuable for its exquisite colour; but it often comes with a split pod.

Albino (Chaundy).—A large white self with broad petals, and the next best to Mrs. Fred, the latter being the finest white self Carnation

Countess of Salisbury (Simonite).—An orange tinted yellow. This flower was reported to beat Germania, but as seen about Birmingham is very inferior to it.

Charmisso (Benary).—A distinct and very fine sort; bright pink,

tinted maroon, with fine broad petal, and of fine form.

Circe (Dodwell).—Blush white, of fine form and quality.

Eunice (Chaundy).—Rosy pink of good form and substance.

Gustave Freitag (Benary).—Much brighter in colour than Mrs. Reynolds Hole, and with a broad petal, good form and excellent pod.

Gillert (Benary).—This is often called Gilbert. Bright carmine

pink colour of large size and fine form.

Hebe (Chaundy).—Blush, tinted with salmon and of excellent form and substance.

John Benary.—Blush pink ground colour striped with carmine and purple. A very distinct fine flower.

Julia Basserman (Benary).—This is of the colour of Souvenir de la Malmaison, but brighter; it is of fine form, with large broad petal and good pod which does not split. A variety which will be very popular for decorative work.

Korner (Benary).—A distinct and novel colour, a pale pink shaded with a brighter tint of colour at the base of each petal and of fine form.

A great acquisition.

Mrs. Joseph Chamberlain (Thomsons).— A charming shade of salmon pink, good form, stout pod, erect habit, and a most desirable variety.

Negress (Thomsons).—Very rich shaded dark crimson maroon, possessing a satiny surface, large smooth petal. A fine flower.

Queen of Crimsons (Dodwell).—An excellent variety. The name indicates the colour.

Santuzza (Benary).—Bright salmon-tinted rose, a grand flower with large petal of great substance and quite distinct.

Topsy (Herbert).—A Negress style of flower, but with a brighter shade of crimson in it. Extra fine in every way, and with a strong Clove perfumc.

Uncle Tom (Dodwell).—This is an almost black, and extra fine

variety.

Vivid (Herbert).—Brilliant deep scarlet. A grand flower with

broad smooth petals and of great substance.

Wieland (Benary).—A distinct and very fine self, bright pink-tinted mauve, broad petal and of the finest form.—W. D.

(To be continued.)

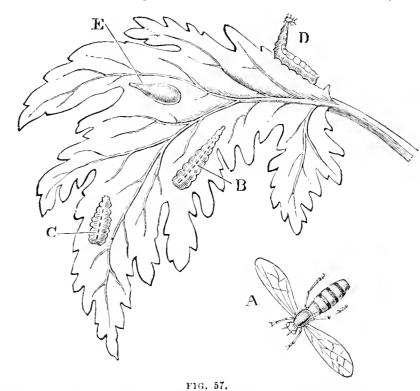

NATURE'S HELPS TO GARDENERS.

WE often hear persons talking about "the balance of power" among nations, and I do not doubt that most nations are anxious that their side of the scales should be the weightiest. Well, we gardening folk in our battles against insect enemies would like to have the balance on our side. Unfortunately, through ignorance, we often throw our weight against ourselves. Once, at a local show, I afterwards took the judges into my garden, and they were by no means ordinary men in their stations, and picking out the larva of one of the Syrphidæ, or smaller that the stations of the syrphidæ in the stations of the syrphidæ, or smaller that the stations of the syrphidæ, or smaller that the stations of the syrphidæ, or smaller that the syrphidæ is the syrphidæ in balance flies, I asked them what they would do with it if they met with it. The verdict was death. They were much surprised when I told them that I had often paid my children so much a dozen for finding them. Where they are often found I will tell later on.

I will allow that to any casual observer this larva, or grub, does not at first sight appear to be different from the many mischievous grubs and small caterpillars that find food and shelter in the leaves, and, alas! often among the blooms of our pets, but a little ordinary care, especially if aided by a pocket lens, ought to save the life of one of the most hardworking helpers that a gardener possesses.

All the ordinary grubs have a perceptible head, generally rounded,

and that looks smoother than the rest of the creature. These larvæ of several kinds of Syrphidæ or balance flies has apparently a pointed head, but if examined by a lens is seen to be made up of three points; still, as it moves, the distinguishing mark is the pointed head; its colour is generally green with some white markings on the back; but if living on the black aphis the green portion is much darker. If at rest it rethe black aphis the green portion is much darker. If at rest it resembles the dogs, whose heads and tails are alike, but if made to move then the pointed head shows itself. They vary in size from the eighth of an inch to perhaps an inch in very fine specimens. In walking there is a much deeper wave of the body than in a caterpillar of the same size. Its legs are rudimentary. It is blind, but when in search of food the pointed half of the body searches all round, and if meeting with an aphis it is seized, held up in the air, speedily sucked, and thrown aside. Their appetite is enormous, and the way in which one of these larvæ will clean a shoot that was covered with aphides is simply incredible to those who have not watched the process. When full grown it fastens itself firmly to a leaf, and, the body contracting, it changes into a smooth body, pointed at one end, rounded at the other, and often looks like a drop of frozen greenish water. In due course it changes into one of the balancing flies with wasp-like markings, the abdomen of which is flat-tened, not round as the wasp. They are beautiful as well as useful, and

A, A* Syrphus fly, the perfect insect. B, One of the larvæ or grubs, natural size and on the move. C, One at rest. D, One holding aloft an aphis, whilst sucking the body. E, The pupa or chrysalis, fixed on the leaf; the head of the fly is now at the thicker end.

could we increase them at will aphides would cease to be the pests they now are to gardeners.

Every observant gardener knows, when the leaves at the tops of his Red Currant shoots are curled and apparently blistered, that the under surface of these leaves is covered with aphides, and that this unhealthy change in the leaves is the handiwork of the aphis. But the instinct of the fly also teaches it that here she may safely deposit one or more eggs. Here my children have, in days gone by, secured dozens for me, which transferred to my Morello trees have helped to save my crop from destruction by the black aphis, or they have been placed on Rose trees or Chrysanthemums.

This year, being very occupied, I did not notice the beginning of mischief on my Morello Cherries, and I was reduced to removing the affected leaves, something like half a bucketful, intending to cover these with boiling water and so rid myself of the pest. But on looking at some of the leaves, literally black with aphides, I noticed some red lines. On taking out my pocket lens, I found these to be very small larvæ of some of the Syrphidæ. I had never seen them so small be ore, and never almost blood red; these were carefully removed with a camel's-hair brush and placed elsewhere, before the blacks were destroyed. Our "helps" are represented on the Chrysanthemum leaf (fig. 57).—Y. B. A. Z.

FLORAL NOMENCLATURE.

WHILE I thoroughly sympathise with "Old Subscriber" (page 356) in his plaint regarding the eccentricity and variability of pronunciation displayed when using the scientific names of plants, I must nevertheless twit him with inconsistency. It is strange that a gentleman who would, if he could, convert every Philistine to the use of the academic and undoubtedly correct "Gladiolus," should contend so strongly for recognition of the contend to the contend nition of the Anglieised plurals of Greek and Latin botanical names. I should have thought that, on such liberal principles, he would have been content with the vulgarly erroneous "Glad-ōlus" or Glad-iolus.

The disorder of pronunciation in floral nomenclature is not an easy

^{*} Several varieties of the Syrphidæ prey on the aphis tribe; most of them belong to the balance fly tribe, that hover over a flower, and often appear almost stationary in

onc to reduce, and though journals have some influence, unanimity in the matter of accent and plurals is never likely to be absolutely established. The more popular horticulture becomes, and the more the knowledge of the ever-increasing number of new plants extends, the greater does the difficulty of agreement grow. The question is, How much use constitutes naturalisation in a language? Botanical names are purely artificial, and constructed for the convenience of international communication between scientific men. Those plants that possess local names have the plural of these names formed according to the usage of the vernacular. But sceing that the scientific names form a kind of lingua franca, ought they to be subjected to distortion according as the person using them in the plural happens to be French, German, English, or Russian? Of course the question is fraught with difficulties, especially when we come to consider those names with the Greek endings (instanced by "Old Subscriber")—viz., is, ma, ops, and opsis. Surely many of us would hesitate, on the score of euphony, before uttering such pluralised forms as Acises, Ganymedeses, Phalænopsises, which suggest the old nursery rhyme, "three ghosteses sitting on three posteses eating bread and cheeseses."

Those who know anything of Greek must regret the substitution of such atrocious sibiliations for the beautifully soft Greek plurals in mata and idés. What havoe the writers of the Restoration wrought with our mother tongue when they took to using "thinks," "walks," "listens," and "freezes" for "thinketh," "walketh," "listeneth," and "freezeth," making it (as Frederick the Great said) like the language in which the serpent tempted Eve! But for this English might be positively agreeable for foreigners to hear. However, it has never been the practice of our race to sacrifice expediency to sentiment, and I am ready to admit that as nine-tenths of the scientific names of plants end with a vowel they suffer little hy heing given the ordinary English plural termination. "Old Subscriber" is right in poking fun at the expression "Narcissi

"Old Subscriber" is right in poking fun at the expression "Narcissi show," hut he misses the mark when he apprehends the advent of "Rosæ shows." The word "rose" is as much English as "violet," and hence it could never be a question of thus pluralising it, as there might be were it still the Latin "rosa." It would be equally absurd to talk of a "Roses shows."—"RIBESES."

Most people will agree with the sentiments of "A Grateful Old Subscriber" (page 356) on this subject. No doubt Glădĭŏiŭs is both right and impossible, therefore we must have an English pronunciation which is classically incorrect. I would strongly support the claims of Glădīŏiŭs rather than Glădĭōiŭs—first, because if the pronunciation is to be English, we should follow the good old rule that "the tendency of the English language is to throw the accent as far hack as possible," and Glādĭŏlŭs is hardly possible; second, because to my ears when I was young there was no other pronunciation, and Glădĭōlŭs is quite modern. But if "A Grateful Old Subscriber" is going to try to induce people to change their pronunciation of even a single word, he has my sympathy, and he will want it before he has done.—W. R. RAILLEM.

HYBRID BRIAR ROSES.

LORD PENZANCE has written me to say that his Hybrid Briars are at present being propagated by a firm of rosarians, and will be ready for distribution hy the autumn of next year. They are beautiful hybrids, between the wild Roses of the woodlands and the Hybrid Perpetuals of our gardens; and partaking as they do of the characteristics of both, will doubtless prove distinct and splendid acquisitions. I think that Briar Roses should be more widely cultivated. Their reign, indeed, is short, but it is exquisite while it lasts. Such brilliant varieties as the Persian Yellow, the Austrian Copper, and the semi-double Rosa Harrisoni should be found in every garden.—David R. Williamson.

HOT SEASON ROSES.

In reply to your correspondent, "W. R. Raillem" (page 358), re the behaviour of dark Roses during the past summer, I am able to state my experience differs somewhat from his own. I never remember having such a number of "burnt" flowers. I do not grow many varieties, but have about fifty dwarfs of Prince Camille de Rohan, and a like number of Abel Carrière, which are grown on a really good Rose soil, hut which requires enriching at the present time. I can safely say I did not cut twelve Roses off them that were up to exhibition form, the majority were very thin in petal, and those burnt badly; in fact I might say scores were never picked for this simple reason. While I am of opinion the hot sun tends to this burning, I think with your correspondent it is not the only cause. Had the bushes been supplied with an adequate quantity of water or liquid manure I feel sure the results would have been different. I am of the opinion that poverty has something to do with burning, in some cases at all events. Général Jacqueminot has never been better with mc; in spite of the thin petals every bloom developed, and their colour left nothing to be desired, at the same time their lasting properties were very brief. It was a case of "here to-day and gone to-morrow." Most of the light-coloured Hybrid Perpetuals were satisfactory,

especially these varieties that object to a wet season. I was surprised to find John Hopper so poor; it was far below the standard in every respect, while the preceding season it was grand. I might add, the majority of my Roses are grown for cutting purposes, and not for the production of exhibition blooms.—ESSEX ROSE GROWER.

MR. MAWLEY'S "ANALYSIS" OF 1893.

I CONFESS to a sense of disappointment on reading Mr. Mawley's explanation (Journal of Horticulture, page 358) of his method of arriving at the various positions the hest exhibition Roses hold each season, more especially in respect to their status at the N.R.S. Metropolitan Show. I have been under the impression while reading his analysis for some years that his figures represented real facts, whereas now I find that he practically uses the figures according to his own fancies. There is no doubt that the analysis must be in any case an arbitrary way of deciding the position of certain varieties, as they are taken only from winning boxes. This year it was of small consequence; but last year, when the competition was so great, as many as twenty-one competing in one class, and many other classes having from eight to thirteen competitors, it would have been a fair criterion of a good exhibition, and very useful and interesting to have obtained the varieties shown by all competitors.

Mr. Mawley says of his method of calculation, "However complicated and unreal the system" (his system) "may appear," it is in reality "a commonsense" way of treating the statistics at his disposal. My view is that when people are dealing with statistics they should deal with the hard facts alone, and not alter such facts to suit any theories they may hold. It is action of this latter kind which gives people the handle to use the saying that figures can prove anything. I prefer a grain of truth and fact to a ton of theory, and I never like to see figures altered. Being a husiness man it may be rather a hard and dry way of looking at the matter; but such is my way of thinking. Mr. Mawley practically arranges what in sporting language is called a handicap, according to his own views of the merits of the various flowers, but without much regard to their previous performances. Of course Gustave Piganeau, Ernest Metz, Ethel Brownlow, and other Roses, may next year be anywhere in an analysis of this kind, and very naturally in future their position will have little interest for me; hut it would be well for the guidance of others that some clear explanation should be given to show that the figures are evolved out of fancy more than fact. In regard to my query as to the number of prize boxes Gustave Pigancau and Ernest Metz were shown in, I used the words "big amateurs," by which I mean those growing at least over 1000 plants of exhibition varieties. I acknowledge that both the above named varieties are indispensable to a hig exhibitor; but from the experience of several leading rosarians, growing many more and oetter Roses than I do, I find t'at other opinions are in agreement with mine.

In regard to seasons in general, and more especially as regards their effects on the Rose Shows of 1893 and of 1879, I may say that, bad as the Crystal Palace Show was this year, it would have been infinitely worse if it had heen held on the 8th July, and no doubt Mr. Mawley will recollect that he and others were very strong advocates for that date, and were very sore at our defeating their motion to alter it.

Mr. Mawley says "We all know what the Drill Hall Show was in June 1891." I merely say we all know what the Drill Hall Rose Show always is—rather a failure? I should be glad to know how many classes there were in the metropolitan schedule of 1879, and how many members the N.R.S. then had. With these figures, which are facts of the past, we could fairly compare 1879 and 1893.—CHARLES J. GRAHAME, Croydon.

WALTHAM CROSS REVISITED.

Many years ago, in the Hollyhock days, when that noble flower gave to gardens a "character" they have never possessed since, I, as one of its votaries, remember well deriving both pleasure and knowledge in reading an entertaining and instructive pamphlet entitled "An Hour with the Hollyhock," little thinking I should ever be privileged to spend an hour with its author, Mr. William Paul of Waltham Cross. Time, however, brings about changes frequently such as are not anticipated, and one of these eventually brought me into contact with one of the most experienced and accomplished horticulturists in the world. That, too. is several years ago, yet subsequent to the dread Puccinia invasion which practically swept the Hollyhock out of the country. True we see the stately flower again in gardens here and there, and occasionally a few blooms exhibited at southern shows, hut they are very poor apologies for the grand varieties of past days when our author spent his "hour" with them. The plants of the present are chiefly raised from seed and treated as biennials, and it would be well if many more were so grown; but anterior to the fungoid scourge they were mainly increased by cuttings or root-grafting and treated as perennials. This is a reminiscence, a passing reference to days on which the minds of many love to dwell, and to which, and the "manners and customs" of the period, many more of a later generation are of necessity strangers.

Since the first visit alluded to, and the last, to be described, all things are not as they once were. For instance, on looking for the path from the platform of the railway station into the nursery, as in the old days, it was not to be found. "Here, porter, I want to go into Mr. Paul's nurseries; there used to be a gate opening to them from here, but I can't find it." "No, sir; there was never no gate from here." "But I once passed through it from the platform into the grounds." "No,

sir, begging your pardon, I think not." "What, then, has Mr. Paul moved his nursery to another place?" "No, sir; it's just exactly where it was, but," with a peculiar look, "we've moved the station." "Ah!" That means a collapse, and acknowledgment that the porter was master of the position. The station is 100 yards or so nearer London now, and instead of walking through it along the pleasant glade to the office at the opposite end, we pass along the side of the nursery, buildings intervening, to the main street of Waltham, turn to the right, and reach the office entrance in practically the same time as before—a steady ten minutes' walk, though there is a side entrance only four or five minutes from the station.

As most persons know, or may learn by a glance at a railway map, Waltham Cross is reached from Liverpool Street station, the city terminus of the Great Eastern Railway—perhaps, at certain times, morning and evening, the busiest station in London, if not in the world. No wonder many a stranger whose life has been spent in the country, the leisurely ways of which have become part of his nature, is not a little bewildered when he finds himself jutted here and there, and hustled about by a mass of humanity rushing for egress or ingress. He may, as many do, as is apparent enough, experience some difficulty in learning where to "take his ticket," and then in finding his train. Let him keep cool and not rush about in a search on the platform, but quietly pass upstairs and book to Waltham. On coming down again he will see right before him a number of clock faces with the hands pointing to the names of stations and number of platforms from which the next outgoing trains start. Amidst all the confusion, the arrangements at these great stations are clear enough, and a person arriving in reasonable time need not miss his train if he does not lose his head, as many do daily.

Not through pleasant suburbs does the train pass on its way to Waltham. We are in the thickly populated busy East. Dwellings, not artistic, are packed together, and "works" of various kinds appear to show their worst sides to the railway. Eventually we come to an opening between the buildings, but much more likely to be occupied with barrels, rubbish, and general lumber than by trees or other forms of vegetation. Yet anon we come to the fields mainly cropped with vegetables, but in no sense representative of the splendid market gardens more distant and westward of the City. Of shaky patched-up greenhouses there is no lack, but they have a depressing rather than an inspiring effect, indeed the whole surroundings are suggestive of a struggle against adverse influences—of marshy soil below and a hazy soot-laden atmosphere above. The outlook improves as we go along, especially as we see the rising ground of Epping Forest in the distance on the right; but it is not until historic Waltham is reached that we feel fairly in the country, and the first really bright and refreshing scene is afforded by the nurseries which skirt the line on the left, but just beyond the station—Rhododendrons in the spring, Roses in the summer, and Dahlias, with the rich tints of various trees during the evening of the year.

Fortunate was Mr. Paul in his purchase of this valuable tract of land between thirty and forty years ago for a nursery. He had it in mind to establish himself nearer the metropolis, but London has spread out since then, carrying with it atmospheric impurities inimical to vegetation, but Waltham Cross is outside the smoke radius and everything is clean. The site is open to all the sun that shines, and the soil is an ideal one for trees ornamental and useful. It is sound loam just above medium in texture, or sufficiently retentive for holding food ingredients, yet free in texture for inducing a fibrous rooting system. It is 3 to 4 feet deep, resting on gravel, and a little below that is the water table. In a wet season superfluous water passes freely away, in a dry one it sustains the trees, as drawn upwards by the sun in the process of capillary attraction. If this were not so, and if fibrous roots were not abundant, specimen shrubs and Conifers transplanted last May could not have lived through the exhausting summer. They have not only "lived" but grown admirably, though of course they had the needful attention as dictated by long experience. Firm, matured wood in fruit and orpamental trees, Roses and various shrubs is the natural growth characteristics of what may be termed the concrete or governing conditions indicated. This is apparent all over the nursery, and such sturdiness above ground can only have its counterpart below—not a few strong fibreless roots which are never produced by such trees, indeed cannot be, but a multiplication of fibres as the necessary collorary of such growth. Excessively rampant growth always did, will, and must mean deep strong root penetration, just as sturdy short-jointed wood ripening to the tips means a free fibrous ramification in the upper stratum of soil. This is so because it cannot be otherwise, and people who are not other than wise attach primary importance to the roots of plants and trees as the precursors of thrifty growth.

To the mere sightseer, who is not a cultivator, the month of October is not the best time for a nursery stroll, though an artist could not fail to admire and long to reproduce the exquisite colour tints assumed by many trees; but the visitor who has some knowledge of the gardener's art, though it may be much less than his more learned guide can teach him, is at no time more interested by an inspection than when Nature is completing the work of the year in the process of maturation. He likes to see fruit trees when the foliage is being scattered at the proper time, the Roses when they are preparing for rest, and trees and shrubs generally when the "leaves are changing yellow and kindling into red," because he can then appreciate the nature and value of the wood better than at any other period of the year. There is plenty to see at Waltham Cross in all those references, much more, in fact, than can be narrated here.

Let us look for a moment at the fruit trees. These we find represented in all kinds and forms, also of various sizes, from thrifty maidens to abundant fruit producers nearly thirty years old, with any number of moveable specimens for immediate bearing, these latter being in demand for furnishing new gardens quickly and filling blanks which are ever occurring in old ones.

Running through the nursery from south to north is an avenue of fruit trees, 400 yards long, in which is planted single trees of nearly 500 different kinds of Apples, Pears, Cherrics and Plums, which are much visited during the fruiting season by connoisseurs of fruits, both amateur and professional. Peaches, Nectarines, Apricots, Figs and Grapes, are grown and fruited under glass. By these means not only are the different soils constantly under the eye for observation and study, but buds, grafts and eyes are, when propagating, taken from fruiting specimens, thus reducing to a minimum the chances of error in nomenclature. Fruit trees, it has been said, are grown in almost every form. There are standards, young and old, short and tall, feathered trees, pyramids and bushes on various stocks, standard and dwarf trained, fan-shaped and horizontal, cordons upright and horizontal in almost unlimited numbers. The fruiting trees, especially Apples and Pears, were the most striking, many being of large size, very symmetrical and thickly studded with fruit buds. Similar trees to those which were removed last winter and bore fruit this summer (1893) large enough to appear at the fruit shows. Of smaller fruits, Strawberries, Raspberries, Gooseberries and Currants abound, the Strawberries being prevented from straying and intermixing by divisional lines of Raspberries, ample space being afforded for both. Many varieties of the different kinds of fruit are grown for meeting garden needs and forming collections. For extensive plantations of a limited number of popular kinds, trees are raised and grown on Mr. Paul's fruit farm in Sussex. The gathered crops of the season were stored in a fruit room recently built on the most approved principles, special features of which are a double roof, double windows and door and thatched sides. It is expected that no heating apparatus will ever be required here. In this nursery the Crab stock is preferred to the Apple, and the Paradise is recommended for private gardens only where the soil is a good medium loam. The Quince stock is used for some sorts of Pears, but the Pear stock is more largely used. The Mahaleb is a favourite stock for Cherries of the Morello kind; an instance of the value of this stock was given. No Cherries could be obtained in a large well cultivated garden until this stock was tried, when the crop proved abundant. Although the summer just past has been more than usually favourable to the spread of various insect pests, the trees here were perfectly clean, and bore no marks of depreciation from these enemies.

The celebrity of this nursery for Roses is well known, and although the flowers were somewhat despoiled by the rain there were several attractive blooms in the masses of Tca-scented and other kinds. The charming Polyanthas were represented by Gloire des Polyantha, Mignonette, Perle d'Or, and the newer and larger Princess Elizabeth Lancellotte. To these may be added the dainty Chinese Little Pet. A fine collection of blooms could be cut of such well proved or promising H.P.'s as Augustine Guinoisseau, Bardou Job, Caroline Testout, Charles Lamb, Climbing Queen of Queens, Clio (a wonderful grower), Danmark, Duchess of Albany, Ella Gordon, Garden Favourite, Gloire de Margottin, Grand Mogul, Gustave Piganeau, Madame Bois, Mme. Isaac Pereiere, Marchioness of Lorne, Mrs. John Laing, Pierre Notting, Pride of Waltham, Silver Queen, Spencer, Star of Waltham, Ulrich Brunner Fils, and Lorna Doone, Kronprinzessin Victoria, and Souvenir Victor Hugo. de la Malmaison were flowering among the Bourbons, and Adelina, Viviand Morel, L'Ideal, Madame Pierre Cochet, and William Allen Richardson were the most floriferous Noisettes. La Soleil was shining among its congeners the Teas and their hybrids, and blooms could be cut of Madame Chauvray, Madame Moreau, Pink Rover, Princess May, Waltham Climber No. 3, all vigorous growers; also of Camoens, Christine de Nouë, Corinna, Ernest Metz, Grace Darling, Gustave Regis, La Boule d'Or, Madame de Watteville, Madame Hoste, Madame Lambard, Madame Pernet, Ducher, Marie Van Houtte, Perle des Jardins, Safrano and its red variety Sunset, The Bride, Waban, and White Lady. This reads like a summer list, and is worth giving as indicating both the mildness of the weather and some of the best autumnal Roses. Plants of appropriate varieties are also extensively and admirably grown in pots for early forcing.

The collection of hardy trees and shrubs it is impossible to pass, as many of them shinc as brightly in their glowing garb of brown, purple, crimson and gold. Among the Acers circinatum, criocarpum, ginnala, Schwedleri, and saccharinum were conspicuous. Berberis Thunbergi (dwarf) was a mass of rich red, as were some of the Cornuses. Two Thorns also compelled notice—Cratægus Carrieri, a nearly evergreen with dark glossy leaves, 3 to 4 inches long, bearing clusters of scarlet fruits, nearly as large as Cherries, and C. prunifolia, leaves dying off scarlet. Euonymus atropurpureus, Gleditschia tricanthos, Kolreuteria paniculata, Liquidamber, various forms of Pyrus, Prunus, and Quercus, with Rhus toxicodendron, Salisburia adiantifolia, Spiræas, and Viburnums glistened in the sunlight.

Clematises in pots, a fine collection, sparkled with flowers, as plunged with other bardy climbing plants for the winter. The Camellia house is one of the features of the nursery. It will be a sight to see in February and March, the plants, young and old, being splendidly "budded;" and the Vines in pots, wherever they may be well grown, will be well worth looking at next year, for more substantial and better ripened canes cannot very well be imagined. The houses generally are

filled with a collection of the most useful spring flowering and other plants most in demand in gardens, and on each side of the long nursery glade are specimens of Hollies and other evergreens, including Osmanthus illicifolius, flowering freely and dispersing Hawthorn-like perfume; also a choice collection of Coniferæ associated with herbaceous plants

Passing through the town we come to an hostelry, Ye Olde Foure Swans, bearing date 1260, and near it the splendid memorial cross, the finest existing of the series commemorative of an historic event in the long past centurics. Not far distant is Mr. Paul's capacious residence, once the home of the late Mr. Anthony Trollope, with well-wooded pleasure grounds and park-like surroundings. Near it is the stately Ailantus tree, with its three main stems, recently alluded to in "The Times," and the alleged unpleasantness of the flowers is regarded by Mr. Arthur W. Paul, the diligent junior member of the firm, as mythical, as the spreading branches are close to the windows of his bedroom, and without causing the slightest inconvenience. The Ailantus glandulosa is a beautiful tree for town or country, and it is a wonder it is not more freely planted.

One is tempted to dwell on Mr. Paul's library, said to contain the finest assortment of horticultural works in possession of any individual except Dr. Hogg. It is a rich collection, ancient and modern, including, of course, the various works of the author, prominent among them being his magnum opus, the "Rose Garden," the most compendious and exhaustive work on the subject on which it treats. An hour with Mr. Paul in his sanctum, as in his nursery, is time well spent, and a man must know a very great deal if he does not learn a little more after spending two hours with the senior bearer of an honourable name, writ large in the annals of horticulture—a privilege the second time enjoyed by—LINDUM.

FRUIT FORCING.

Peaches and Nectarines. - Earliest House. - The trees in this structure have been at rest for some time, the roof lights having been removed when the wood was sufficiently firm and the buds formed, but not over-developed. The house was thoroughly cleansed when the leaves were all down, the trees untied, pruned, dressed with an approved insecticide, re-arranged and tied on the trellis, the border surface dressed, all put in complete order ready for a start at the proper time, and they are now in a promising condition. The roof lights will not be replaced until early in December. Where the roof lights have not been removed strenuously avoid allowing the soil to become dry at the roots of the trees, as this is sufficient to cause the buds to fall. If the trees are weakly and the buds plenteous a supply of liquid manure will be of great benefit. It is also advisable to remove the surface soil down to the roots, removing some of the old from amongst them, and supply fresh loam, not covering the roots near the collar more than 2 or 3 inches. If the loam be of a light nature add a fourth of clay marl, dried and pounded, and a barrowload of wood ashes to every cartload of loam, thoroughly incorporated, making it firm about and over the roots, and giving a good watering. Borders that have a close moist surface, and are rich in humus through heavy dressings of manure, may be dressed with freshly slaked lime, using about a bushel per rod, and mixing it with the soil as deeply as practicable without disturbing the roots to any great extent, omitting the top-dressing before mentioned. If the soil is very close and deficient of grit and ealcareous matter, a dressing of calcareous gravel about an inch thick, mixed with the soil as deeply as the roots allow, would improve its staple and component elements. It should be practised on both the inside and outside borders. Complete the pruning and dressing of the trees, cleansing the house, and admitting all the air possible.

Second Early House.—The trees that were started at the new eary or soon afterwards have been at rest a month, and those started in February are now leafless; they should be pruned, after untying, dressed, and re-arranged on the trellis. This, with a thorough cleansing of the house, makes an end of adult insects and larvæ before they have time to hibernate in the crevices of the bark and chinks of the woodwork and walls. In pruning early forecd trees it is not desirable to cut away too much wood, nor proceed on any hard-and-fast lines, but confine it to removing any useless parts that have escaped removal at thinning after the fruit was gathered, and shortening any long shoots to a double or triple bud, making sure that one of them is a wood bud. This will mainly be necessary to originate growths at the required place for furnishing the trees, for shoots that are well ripened need not be shortened and those of 8 to 12 inches length should be left entire, as they usually have a few wood buds at the base and one at the extremity, those between those points being usually blossom buds. It is, however, a mistake to retain much wood, which weakens the trees in flowering, and there is not space to train in the young growths without crowding. Treat the trees in other respects as advised for the earliest forced, also he house and borders.

Third Succession House.—This being started in February, the trees will now be leafless, or nearly so, and should be subjected to similar treatment to the earlier ones, losing no opportunity of pushing forward the pruning, dressing the trees, and having all needful work done. If the wood is thoroughly ripened, the roof lights may be removed with advantage. Where the roof lights are not moveable do not allow the soil to become too dry, and admit air to the fullest extent, securing as complete rest as possible. Any trees growing too luxuriantly or not setting and stoning the fruit well should be root-pruned or lifted.

Late Houses.—The late varieties are over this season sooner than usual, and the trees are shedding their leaves. It will be advisable to remove the roof lights as soon as the foliage is sufficiently advanced, but where green leaves hang long it is an indication of unripe wood, and the roof lights must not be removed for some time longer. If this condition prevails generally in the trees they should be lifted carefully and be root-pruned. When this is performed judiciously it will not prejudice next year's crop, but it must be done when most of the leaves are down and the wood firm, keeping the house rather close, the trees syringed, and shaded if the weather be bright. Under ordinary circumstances as to the weather these precautions are not necessary. It is only when the trees are gross and the wood unripe that the careful treatment is requisite.

In the case of young trees it will suffice to take out a trench one-third the distance from the stem the trees cover of trellis, and down, so as to cut off all roots to the drainage, leaving the trench open for a fortnight, not allowing the soil in the radius to become so dry as to distress the foliage to a severe degree of fiagging, but not giving any water so long as the leaves maintain their persistence, and then the trench may be filled in, making the soil firm. This will check the tendency to exuberance and late growth, and ripen the wood and plump the buds. Luxuriant trees which may not safely be bodily lifted on account of their long, strong and few roots, may be treated in a similar manner, and a year afterwards they may be lifted.

Unheated Houses or Wall Cases.—With a proper selection of varieties Peaches and Nectarines may be had from these structures from the middle of July to the middle of October. The structures should have south or south-west aspects, but they may have a west aspect in the southern parts of the country. Peaches:—*Alexander, Early Louise, *Hale's Early, Dr. Hogg, Crimson Galande, *Dymond, *Royal George, Grosse Mignonne, Goshawk, Alexandra Noblesse, *Bellegarde, Barrington, Grosse Mignonne, Goshawk, Alexandra Noblesse, Bellegarde, Darrington, Princess of Wales, Gladstone, Sea Eagle, Walburton Admirable, and Golden Eagle. Nectarines:—Early Rivers, Lord Napier, Goldoni, Darwin, Stanwick Elruge, Rivers' Orange, Milton, Pine Apple, Dryden, Newton, Spencer, and Victoria. Those requiring only a few may select those distinguished by a star. The chief thing with trees in unheated houses is to train the shoots thin so as to secure stout short-jointed, thoroughly solidified growth, to allow unobstructed light, and provide efficient ventilation. Proper attention must, of course, be given to efficient ventilation. Proper attention must, of course, be given to cleanliness and due supplies of nourishment, but the most important point of all is retarding the blossom in the spring as far as practicable. This is best effected by removing the roof lights, and allowing them to remain off until the blossoms are swelling and showing colour. has a good effect on the trees by the cleansing influence of rain, also in securing the thorough moistening of the border. Such trees can be kept perfectly under control by occasional lifting and root-pruning as may be considered expedient. Over-luxuriance or a tendency to late growth is overcome by judicious root-pruning and careful lifting, which should be done after the wood becomes firm, and whilst the foliage is still upon the trees. When intelligently practised lifting and laying of the roots near the surface and firming the soil well, is the surest remedy for trees that fail to set and stone full crops of fruit.

Pines.—Liberal ventilation should be afforded to pits or houses containing young plants when the weather is favourable, and avoid too much moisture, as over-damping, keeping the surfaces of the house constantly saturated, is more injurious than otherwise. Water will not now be often required, yet the plants must not be neglected, looking them over every week or ten days, watering such as require it, as too great dryness at the roots causes a stunted growth and it is not easy afterwards made free.

In the fruiting department lose no opportunity of admitting a little air early, closing the house at 85°, keeping the night temperature at 70°, or a few degrees less in cold weather. Remove all gills and superfluous suckers, retaining one only, the best to each plant. Suckers on successional plants that appear before the fruit should be removed, except an increase of stock is urgent, and then the fruit is more or less sacrificed to the nuckers.

At this time of the year it is usual to make new beds of fermenting material and prepare them for the young plants. Tan is the best for the purpose, retaining its heat longer than any other, and subsiding least. In forming beds of it place lightly together. Oak or Beech leaves are a good substitute for tan, which should now be collected, and as dry as possible. The leaves should be firmly pressed so that they may not sink much, and also to regulate the heat and prevent it from becoming too violent and soon spent.

Cucumbers.—The temperature should be maintained at 70° at night, falling 5° when cold, 70° to 75° by day artificially, advancing to 80° or 85° with sun heat. Admit little air at the top of the house whenever the weather is favourable, but it must be done without lowering the temperature, it being better to shut off the top heat for an hour or two when the sun is powerful than to ventilate when the wind is very cold.

Except on very fine days the syringe should be laid aside, using it chiefly for damping the paths, walls, and other surfaces in the morning and afternoon in warm bright weather. Supply water or liquid manure to the roots as required, and always of the same temperature as the house. Cover the roots with warmed soil as they protrude, and sprinkle a little superphosphate over it occasionally as an incentive of root action.

The autumn fruiters being now in full bearing must not be over-cropped, therefore remove the fruit when it attains a useable size, also all deformed fruit. Examine the plants at least once a week for the removal of bad leaves, and for stopping the shoots a joint beyond the show for fruit, and cutting away all superfluous growths. Let the winter fruiters advance well up the trellis before stopping them, training the side growths right and left of the stem, and not too closely, so as to secure well developed growth and foliage. Allow few or no staminate flowers, but remove them with tendrils as they appear, and add fresh warmed soil to the hillock or ridges as the roots show at the sides.

THE KITCHEN GARDEN.

Asparagus.—Not till the tops turn to a yellow colour should these be cut down, and then only to within about 4 inches of the ground, the stumps being left by way of an indication of the whereabouts of the crowns. Seed is very abundant this season, and if strong growths, heavily furnished with berries, are suspended in a cool, dry shed the cleaning will be a very simple matter next spring. The custom of heavily dressing the beds with solid manure, the soil from the alleys being deposited on this, is not recommended. It keeps the beds cold and wet during the winter, and destroys good roots that ought to be preserved. If Asparagus beds must have a surfacing of rich manure, defer applying it till next February or March.

Beet.—Whilst the mild weather lasts the roots will continue to grow, but the first sharp frost will check further progress. If a little soil could be drawn up to the plants so as to quite cover the roots they may remain where they are for some time longer, but if left exposed to a severe frost they might be spoilt. The roots are safe under cover of some kind. All should be forked out of the ground carefully, snapping the thick roots meaning a loss of colour throughout by bleeding, and the tops ought not to be trimmed off too close to the crown. If there is space in a cool shed that is the place to store Beet, all being packed crown outwards in either fine soil or sand. The roots may also be stored in a cone-shaped "clamp," and covered with straw and soil after the manner of Potatoes. The Turnip-rooted forms are the worst to keep, and these ought, therefore, to be used first.

Carrots.—Fully grown roots of these are also best out of the ground before severe frosts can reach them. All should be lightly cleaned, and the tops cut off nearly close to the crown, being then packed in sand or fine soil, much as advised in the case of Beet. Late Carrots should be left undisturbed. They will continue to grow when the weather is mild, and are much more tender and sweeter when pulled just before being wanted for use. Sowing in frames on gentle hotbed should commence now, especially where there is a constant demand for quite small roots. The French Forcing is the best for autumn sowing.

Other Root Crops.—Salsafy and Scorzonera keep the best in the ground, a few roots being lifted and stored for use whenever severe frosts are anticipated. Treat a portion of the crop of Turnips similarly to Carrots. Chicory may either be lifted and stored in cool quarters, the tops not being severely shortened, or the roots can be left in the ground and be lifted according as a few are wanted for placing in a Mushroom house or cellar to produce the requisite supplies of well blanched leaves. Parsnips not only keep better in the ground than they do when lifted and stored in sheds, but the quality also is superior. Jerusalem Artichokes are still growing strongly, and the roots will be of even worse shape than usual, the quality also suffering from this second top and tuber growth. These should not be interfered with at present. Later on, or after frosts have crippled the tops, these may be cut down and a portion of the beds strawed over so as to admit of roots being dug if wanted at any time. Onions keep the longest when hung up in cool dry sheds where they can be lightly protected if need be during the coldest weather. Binding them closely and neatly to stout string or short sticks is good wet weather work for the men, and the sooner the bulk of the roots are hung up the better.

Potatoes.—Much of the work of Potato lifting has been already completed in the majority of private gardens, and during dry days should be persevered with in the open fields also. The sorting over and storing ought to keep pace with the lifting. All the "ware" tubers, or those intended for marketing or home consumption, should be placed in one heap, good medium-sized tubers being selected for planting next season, quite the smallest, and any found slightly diseased, going to the pigs. Large numbers of "ware" Potatoes are best stored in clamps, or conical heaps not more than 4 feet wide at the base and of any length. These should be formed on the top of the ground, a well-drained site being chosen and only covered with straw for the first fortnight. The whole heap should then be turned, beginning at one end and re-forming the heap as the work goes on, this being done with a view to getting rid of all that have thus had a good chance of showing that they are diseased. Re-cover heavily with straw or strawy litter, and then bank over with soil dug from round and about 1 foot away from the heap. Potatoes will keep well undug, always providing the rows were heavily moulded up, and few or no tubers are near the surface.

Seed Potatees.—It is during mild autumns when so many seed or planting tubers are greatly weakened, and in many cases quite spoilt by premature sprouting. When those that have been dug earlier in the season are left in heaps for several weeks sprouting inevitably commences; long weak shoots resulting, unless this is prevented by thinner storing. The Ashleafs ought, particularly, to be set up on ends closely together in shallow trays, these being blocked up one above another in a cool light shed. Thus treated, and duly protected from frosts, they will not lose their first strong sprout, and heavier and earlier crops of Potatoes be had next season accordingly. It is scarcely possible, in most gardens, to treat the tubers of main crop varieties similarly to the Ashleafs, nor is this particularly necessary; but these ought, however, to be stored as thinly as space will permit, and be kept cool. Light is a good preventive of premature sprouting, and should only be excluded whenever it is necessary to afford additional protection from frosts. The best results invariably attend the practice of planting well-kept, medium-sized tubers whole, it being false economy to reserve the small Potatoes for planting purposes.

APIARIAN NOTES.

HINTS FOR BEGINNERS.

(Continued from page 365.)

The swarm-catcher I use is perhaps the first of the kind ever made, and, in my opinion, is still superior to any other. It consists of a light box of wood about one-eighth of an inch thick, or of wire cloth lined with stout calico, but fastened at the bottom edge only, the top being supplied with loops and cords so that it can be held up or lowered when the bees are transferred from it to the permanent hive by simply loosing the cords. The weight of the bees causes the bag to drop to the top of the hive, and the bees on finding the slight pressure retreat to the hive beneath in a few seconds, thus obviating all risks of them or the queen taking a second flight, or of stranger bees joining and killing the queen. The poles generally used are joined by ferrols to any length, and have on the top a swivelled arm on which are fitted the two pulleys, over which the cord works to lower the swarm-catcher. I hope the foregoing may be sufficient to enable the beginner to make one for his own use. It must be borne in mind that the swarm-catcher is made to go inside the super-protector, without which it would be of less value.

Supering.

After hiving comes supering. When should the supers be put on? is a question oftener asked than can be answered satisfactorily. Supering newly hived swarms, and the size of hive to be employed, are matters which no one can say positively what, when or how everything should be done. Experience alone must be the sure guide to beginners, locality and season being potent factors. In order to assist those commencing bee-keeping, however, we shall suppose a prime swarm has issued and is safely hived. When the honey flow is great the hive should not have more than two divisions; in fact in one division having full sheets of foundation, or some wrought out combs with supers added, the bees will take to them at once, and when comb building has been well forward in them, say in two days after, add a second division also full sheeted or combed. If the swarm is before the honey flow give it two or the three divisions according to the time ahead and strength of swarm. Generally speaking, a prime swarm comes to full strength and swarming point again in from five to six weeks after being hived.

If a prime swarm in two divisions at first be deprived of its queen and a young fertilised one introduced, and at the same time a third division added, swarming for some time will be delayed if not altogether stopped. The same treatment applies to stocks unswarmed, but the bee-keeper must determine according to his locality the best time to strengthen hives by superseding old queens, by introducing young ones, or the joining of swarms. These should all be done so that the hives may be in full strength at the time of the greatest honey flow. Thirty days elapse from the time the eggs are laid till the bees work in the field, but inside the hive they act as nurses, and others work shortly after birth.

To catch the flowers at the proper season by full strength hives is of the greatest importance. Sometimes the bee-keeper is greatly taxed how best to accomplish that, and manipulations have occasionally to be resorted to to accomplish that in some localities that are quite unnecessary in others. — A LANARKSHIRE BEE-KEEPER.

(To be continued.)

BEE-KEEPING-TEACHING BEGINNERS.

CAN you tell me of a useful little work on bees, very simple and suited to a beginner? We have about eight hives, and since the sudden death of a brother in the summer no one understands how to manage them. A bee-master took the honey for us about the beginning of August, and reported the swarms strong and healthy; but as he does not come again till the spring, I wished to ask if there is anything to be done in the meantime. We have "Modern Bee-keeping," a handbook for cottagers, but perhaps you can recommend me something better?—W. H. B.

[As there is no royal road to learning, so there is no book which alone can teach beginners sufficiently, and guide them in all matters connected with bees. Nature's book, and with it experience, form the best groundwork for the young apiarist. Neighbour's "Apiary," and the "A. B. C. Book," by A. T. Root, are perhaps as good as any, the latter touching upon many things not otherwise found in bee boooks.

The bee-master who took the honey in August, and reported the swarms strong and healthy, should have told you whether there was sufficient food in the hive to last till late in the spring; it ought then to have been not less than 35 lbs., and at the present date 20 to 30 lbs. He should also have shown you how to feed and protect the hives against the frost and storms of winter.

If the hives are not provided with sufficient food supply it at once until they have at last 20 lbs. each stored. If single-cased (by far the best) wrap several plies of woollen or other material around them, then over that an oilcloth or an archangel mat, covering the top of the frames with a porous quilt of some sort, then over that some dried grass or several inches of soft woollen material

A ventilating floor is the safety valve of every hive. As a makeshift a rim 3 or 4 inches deep covered with perforated zinc, seven holes to the inch laid on the top, not nailed, keeping the original floor beneath all. Be sure the top is defended by a water-proof covering of cloth or iron so placed as to leave a free current of air between it and the covering. The Journal of Horticulture is the best instructor. The articles appearing weekly for the guidance of beginners, if read and thought over, will enable anyone to become proficient in a year. Some of the greatest achievements in modern bee-keeping were learned first from its pages.—A LANARKSHIRE BEE-KEEPER.]

TRADE CATALOGUES RECEIVED.

Little & Ballantyne, Carlisle.—Trees, Roses, Herbaceous, Stove and Greenhouse Plants.

The Surrey Orchard Co., Redhill.—Bulbs.

Charles Turner, Royal Nurseries, Slough.—Roses, Fruit Trees, and Nursery Stock.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Covering Glass Structures in Winter (J. Everaerts).—You act wisely in drawing down your lattice and other blinds over the roofs of your houses in winter to prevent loss of heat by radiation and consequent waste in fuel. We do not understand why the custom is not more general, but we know that in many instances it would be advantageous to use blinds less in summer and more in winter. If growers of Chrysanthemums were to use blinds over the plants on clear cold nights, the damping and premature decay of many blooms would be prevented. The use of good blinds in winter would considerably lessen the onsumption of fuel.

Grubs in Cyclamen Pots (E.).—The grubs are the larvæ of a destructive weevil (Otiorhynchus), a brownish beetle-like creature which feeds chiefly at night on various kinds of plants, and may be found with the aid of a lantern and destroyed. The grubs are difficult to destroy—a decoction of hellebore made by dissolving 2 ozs. of the powder in a gallon of hot water and applied at a temperature of over 100° might be tried. It would not injure the plants.

Marechal Niel Roses (S. S.).—We should not have adopted your practice, though we hope no material harm will result. The roots would no doubt strike downwards and find the moisture you have denied them near the surface. Root-drying does not always mean wood-ripening, as has been over and over again indicated in our columns, but often means wood-starving. We advise you to make the border moist right through in the best way you can, using pure water, then a week afterwards follow with good liquid manure.

Prices of Brick and Concrete Garden Walls (W. M. B.).

—The prices vary with the material, distance of carriage, and labour. A 9-inch thickness will do for a wall of 6 feet height, and with bricks of good quality, cost about 3s. 9d. per superficial yard, including footings and copings. Concrete walls generally "batter" upwards to 9 inches from a base of 15 inches, and equally on both sides. If the materials have to be bought and cement is used the cost is about the same as a brick wall, generally 4s. per superficial yard. Where the materials are handy and the work done by skilled labourers the cost is considerably less.

Dressing the Wounds of Apple Tree (Inquirer).—It was not intended to deprecate the use of pigments for dressing the wounds caused by cutting off large limbs, but we have seen disastrous consequences follow the use of gas tar on fruit trees, and do not advocate its use on any tree with a smooth bark, as Apple trees ought to have to be healthy and fruitful. It is usual to dress the wounds of forest trees with gas tar (or preferably lead-coloured paint), and no injurious results follow, in consequence of the thickness of the bark, whilst the pores of the wood are closed by the pigment. For any cuts such as you allude to we should prefer lead-coloured paint to gas tar, but for the cankered wounds proceed as advised with the sulphate of copper solution, washing them well out, and then apply a plaster of cow manure and clay to encourage the growth of the bark over the wound. The sulphate of copper solution is in nowise a preserver of the wood from wet, but it acts fatally on fungi and their germs.

Transparent Patches in Apple Flesh (R. I. L.).—The hard wax-like patches on the Apple consist of pulp of greater density than the other parts of the fruit, the cell walls having been ruptured, probably on account of their thinness, and the extravasated juices are retained, giving the blotches a firm transparent appearance. There are, of course, no air spaces in this part of the fruit, but there is a certain amount of air, as air bubbles form on the microscopic section, and a few perfect cells exist amid the gelatinous-like flesh forming the blotches. In the other parts of the fruit the cells are unusually large, and the flesh is much softer and lighter. The substance proceeds directly from the internal parts of the fruit, and is intimately connected with the carpel or core. Its extravasation is most pronounced in hot soils and seasons, and is restricted to certain races, such as the Muscovy or White Astrachan (Transparent Apple), which is remarkable for its gelatinous-like blotches in the flesh, and sometimes the whole fruit is transparent, with a texture of flesh resembling a stone fruit, and very crisp, juicy, and richly flavoured. The transparent blotches sometimes occur in Gravenstein and in some of the Calvilles. It is not a disease, but a peculiality of type, transmittible from the parent and inherent in the progeny. The threads pervading the gelatinous-like substance are not fungal, but belong to the cells which have had their juices extravasated.

Making a Vine Border (George).—As there is about $2\frac{1}{2}$ to 3 feet of good soil resting on rather sandy gravel, we should not for marketing purposes indulge in a costly border, for if profits are to be realised in these days of keen competition, it must be by strict economy both as regards capital and labour. If the soil is naturally well drained, water not lodging in the sandy gravel, nor at any time rising to within 4 feet of the surface, but percolating away to lower ground as it falls and passes through the soil, there will not be any necessity for tile drains to carry off the otherwise superfluous water. Rubble for drainage will not be necessary, and all you need do is to chop the turf up rather roughly, mix with it the lime rubbish and a quarter of the fowl manure, place on the border evenly, and mix the whole with the good soil by trenching, so as to form a staple 2½ feet deep, loosening the soil at the bottom, and leaving it there. This border will grow as good Grapes as need be with due attention to surface dressings and supplies of water or liquid manure. Where water lodges in the subsoil, an excavation should be made 3 feet deep down to the sandy gravel, with the bottom sloping to a drain at the front and longitudinally of the proposed house, having the drain about 1 foot below the bottom of the border, with proper fall and outlet, placing rubble on the 4-inch drain level with the bottom of the border. The front wall of the house should be arched so that the roots may pass from the inside to the outside border, 9-inch pillars sufficing, with skew-back arches, the under side of their crowns being level with the proposed level of the border, and about a foot of brickwork above the crown of the arches will be sufficient height of wall in front and at the ends. About 3 feet height of front lights opening the entire length of the house, or every other light at least, will be necessary. Top lights will also be necessary in the sloping roof, about $2\frac{1}{2}$ feet wide, and preferably opening

PERHAPS at no season of the year do the eyes of those who revel in exquisite tints and infinite gradations of colour find so much to admire as during the autumn, when the surface of every woodland, and that of numerous groups or belts of trees, exhibit the unapproachable beauty of Nature's colour blending. The spring, with its tender green leaves and blossoms of pristine beauty; the summer, with its sunny skies, waving crops, gorgeous flowers, and deep green leaves have each a beauty of their own; but to the leaves of autumn must be awarded the palm for the display of the greatest diversity of rich tints, which each year teach us useful lessons in the boundless art of colour blending:

The enjoyment to be obtained from a studied survey of autumn foliage and berries is not confined to the views noticed in the open air, for with such a wealth of materials before us we have learned to utilise them for artistic adornment in many ways. At the harvest festivals in our churches they, in combination with fruit and flowers, are befittingly employed to show the varied bounty of Heaven's gifts, and add a higher touch of beauty to the buildings wrought by human hands. In the embellishment of the homes of the affluent they also play an important part, and those who carry out this kind of work look with pleasure on the autumn season, when, by the aid of the rich materials at their command, artistic arrangements and unique effects are easily produced. Few receptacles are better adapted to displaying branches and shoots of autumn foliage than tall trumpet-shaped glasses. We have recently been filling such with branches of Beech covered with bright brown leaves, long shoots of Dogwood carrying bold crimson foliage, graceful plumes of Asparagus dotted with red berries, Ampelopsis sprays, and drooping Larch shoots arranged so as to hang in thinly disposed festoons of waving lengths over the sides of the glass. Specimen blooms of that fine Chrysanthemum Mons. R. Bahuant, cut with long stems, and arranged with shoots of Dogwood and Berberis aquifolium bearing well coloured leaves, have been greatly admired. White Chrysanthemums, or others having bronze shades of colour, look exceedingly effective when given a background formed of shoots of this Berberis. Indeed, the leaves of this useful shrub, obtained from plants growing in different positions, exhibit such a great variety of colour that they are invaluable for arranging with many flowers of bold type. Leaves on the same shoot sometimes vary from a dull bronze to bright red.

Few things are more striking when employed as tracing for dinner-table decoration than these coloured leaves, as they are bold and distinct in outline as well as beautiful in colour. Shoots of the common Plane tree about the middle of October we find very useful for mingling with other foliage, the pale green in the centre of the leaves, shaded to light yellow at the edges, supply shades of colour which harmonise so well with the richer tints of other leaves. I do not remember to have previously seen autumn foliage so generally good as it has been this year; the recent rains acting on a warm parched soil seem to have had the effect of infusing a glow of colour into leaves which at one time were turning a rusty brown, quite unattractive when compared with their appearance now. A large Horse Chestnut overhanging a lake in the park here has during the last fortnight been a picture of

surpassing beauty. The groundwork of the leaves is of a bright yellow colour. On each side of the ribs streaks of bronzy red show up distinctly; these streaks are gradually shaded and suffused with dull rose and pale pink. The effect produced by this large surface of bright, yet exquisitely shaded colours, rivets the attention of every beholder.

The Deciduous Cypress (Taxodium distichum) also contributes telling autumn foliage, and is well worthy of planting on that account, especially in the vicinity of masses of large specimens of the various kinds of Laurels; the bright brown colour of this Taxodium is then shown up to the best advantage. For arranging with other foliage in a cut state it is also excellent, as its Fern-like branches supply the light feathery material needed for mixing with bolder foliage. Many other trees and shrubs might be enumerated which supply foliage of rich colour to brighten the landscape or adorn the interior of "England's stately homes." There is, however, one member of the vegetable kingdom whose usual place is in the precinct of the kitchen garden, which must be mentioned in connection with this subject. I refer to the shapely Carrot, the coloured tops of which can vie in beauty at the present season with the fronds or leaves of the choicest exotic. The great diversity of colour to be found in Carrot tops renders them especially suitable for mixing with flowers of all shades. We frequently place a groundwork of them in large bowls of low glasses, and then dot among them trusses of Madame Crousse Ivy-leaved Pelargoniums, which combination is both novel and pleasing. The rose-coloured flowers of Anemone japonica, and others of similar shades, as well as all white ones, are also exceedingly effective when loosely arranged with these beautifully coloured Fern-like leaves. I ought previously to have mentioned that shoots of the various varieties of Ghent Azaleas have now some of the most brilliantly coloured leaves to be met with, which render the beds occupied with them almost as showy as when in flower. When shoots are employed for decorative purposes in a cut state I find the leaves adhere to them until quite withered, and last a long time in good condition. Cut only those shoots which have no central flower bud, otherwise the beauty of blossoming time will be much curtailed.

Turning to the many forms of autumn berries we find the various species and varieties of Crategus produce them in abundance. Perhaps the most showy among them are the clusters of bright scarlet ones borne on the branches of C. pyracantha. These are well adapted for arranging with the paler-tinted leaves, judiciously intermixed with others of deep green, a few Grasses afterwards being added to give lightness and finish. The common Hawthorn, C. oxyacantha, is this year loaded with "haws." Large branches may frequently be cut from trees and hedgerows without injury to either. These look particularly well if placed in tall trumpet-shaped glasses. They should be thinly disposed, and allowed to hang well over the sides; the arched branches then exhibit their natural grace, and do not require associating with other materials to display them to the best advantage. The rich purple berries of the common Privet, bright scarlet "hips" of the Dog Rose, large dark coloured clusters of Elder berries, each in turn prove welcome for indoor adornment. Euonymus europæus (the Spindle Tree), with its long elegant branches on which rose-scarlet berries are freely produced, yields the palm to none in its appropriateness for basket and vase decoration. It is deserving of more extended cultivation, for it thrives in dry stony places where many other things do not. In some parts of the country the Spindle Tree grows abundantly in the hedgerows, and is very beautiful.

With the materials already alluded to dwelling rooms may be made bright and attractive without employing a single flower, though when foliage, berries, and flowers are each used the highest artistic effects are produced, but at the present season I always like to arrange one basket or vase in each room entirely with foliage and berries, as they seem to mark the progress of the waning year.—
H. Dunkin, Castle Gardens, Warwick.

TOMATOES IN 1893.

The past season, so far as my recollection goes, has been about the best I have ever known for outdoor Tomatoes. Plants that were turned out of 6-inch pots the end of May and with the first trusses of bloom showing had some ripe fruits before June was out, and throughout July and August fruited abundantly. They were planted against a south wall in vacant places between the fruit trees, and supplied with water about twice a week. These plants were raised from seed sown the end of March, but the general sowing for outdoors I made about the middle of April. The varieties grown here this year were Ham Green Favourite, Conference, Challenger, Ladybird, and also a good local sort, but other kinds, such as Perfection, Sutton's Maincrop, and Sutton's A1, grown in neighbouring gardens, have done remarkably well. The weather was so dry throughout the summer that more water than is usually necessary was required.

Some seedlings of Challenger and Ham Green Favourite that were left in the seed pots, and about 2 inches high, were potted the beginning of June, grown quickly on a shelf in a Cucumber house for a fortnight, then hardened off for a week, and planted against a south border a yard asunder. A strong stake 3 to 4 feet high was thrust in at the same time for each plant to be tied to. were two dozen plants of each of these varieties, and they have given less trouble and produced finer bunches and more weight of fruit than any forty-eight plants against the wall. The ground had been newly dug, and although the weather was so dry in May, the soil was moderately moist, also warm, so the Tomatoes grew quickly, and reached the top of the stakes in a much shorter time than I had ever seen before. When the fourth truss of flower on each plant was seen the point was pinched out and all further growth was suppressed. As they grew, all side laterals were pinched out, and when the fruit was fairly set some of the large robust leaves were reduced one-half. Some of the clusters weighed more than 2 lbs., none less than 11 lb., and the fruits were even

and finely shaped.

I believe, and I have often done it myself, that Tomato seeds to produce plants for the open air are sown much too soon. The plants become root-bound before the weather is such that they can be safely turned outdoors. The middle of April is quite soon enough to sow the seed in heat, and when the plants appear they should, as soon as possible, be moved to a shelf in a sunny greenhouse to keep them sturdy. After potting an intermediate temperature is best for a fortnight, and then another fortnight in a greenhouse or frame, with plenty of air if the weather permits. One point of importance is not to plant in open quarters till the ground gets fairly warm. It may be warm enough under a south wall the end of May, but in the open the middle of June is better. Too much stripping of the leaves I do not believe in, but keeping the ground very clean with a Dutch hoe between the plants is good for them; the frequent stirring and clean surface of the soil acts like a wall in radiating the sun heat about the plants. A yard each way from plant to plant is not too much space. If only four bunches of a pound each be obtained from each plant it will well repay the cultivator, but the past season has given more.—A. Harding, Orton Hall.

SOILS AND CLIMATIC CONDITIONS IN RELA-TION TO HARDY FRUIT CULTURE.

According to the theory of the author of a paper I perused some time since, which treated conjointly on geology and horticultural chemistry, certain of the constituents of good soils required the agency of favourable climatic conditions to liberate them which otherwise would be held in suspension. Such a theory is, of course, endorsed by recognised authorities on the latter of the two sciences referred to, and the writer further indicated that such favourable climatic conditions formed one of the chief reasons why most foreign products were so perfectly developed and matured. On looking back at garden crops in general, and hardy fruits in particular, of the past season, it is seldom indeed that northern cultivators are enabled to record a counterpart in experience approaching so nearly to the standard of perfection set forth in the text just quoted. In the latter department especially Apples in this county (Ayrshire), taking size, quality, and finish into calculation, have been pronounced an unprecedented display at least at one of the two principal county exhibitions. Some of the most conspicuous examples of high culture among culinary sorts included Ecklinville Seedling, Warner's King, Emperor Alexander, Cellini, and Peasgood's Nonesuch. The latter variety heads the list for weight, a first prize stand containing six superb specimens, which were said to average within a fraction of 1 lb. each. These were grown at Trochrague Gardens in the valley of the Girvan River. The mean temperature in that locality is somewhat

higher and the atmosphere more humid than in most other parts of the county, the soil in the gardens being heavy. Mr. Goldie, the gardener, informed me that his stand of Apples was selected from a tree bearing an aggregate number of 200 fruits or thereby.

Referring to Apples from wall trees growing in soil having a tendency to a light texture, I have noted that the fruits of some varieties on a south aspect, although better coloured and flavoured, are not up to the size they attained in wetter seasons, of which may be instanced Early Harvest and Lord Suffield. On the other hand Ribston Pippin and Greenup's Pippin are of full size and well finished, which is unusual for the latter at the middle of September so far north. A few fruits of Grange's Pippin ripened a few days latter on a west aspect. These were also of fair size, and in common with the two last named varieties were from a young tree. tree of Ribston Pippin on a south aspect yielded a gathering of very fine specimens, although taken as a whole they were not so evenly in size as from the younger tree on the same exposure, but decidedly a better crop in every respect than for many years past. A young tree of Cellini, a choice culinary sort, on a west aspect, produced a crop of good size and extra colour. Another useful and handsome looking culinary variety is Saltmarsh's Queen, but the only tree we had was necessarily allocated to an eastern aspect where the solar conditions are less favourable for the full development of most Apples. Here it carried a good crop of medium but evenly sized fruits though lacking in finish. Among a number of old trees in an orchard we have a few of the Gravenstein Pippin These, which for several years past have steadily deteriorated in size and quality, have this season produced abundant crops of greatly improved fruits in the above respects, many of them being extra well Occasional applications of sewage water diluted no doubt contributed considerably to the combined conditions necessary for the swelling of the fruit.

Taken in the aggregate, Pears grown in the same description of soil as Apples have been more uniform, this result being probably due to some extent to the general condition of the trees with regard to vigour. Among carly varieties on south and west aspects Beurré d'Amanlis, Jargonelle, Williams' Bon Chrêtien, and Hessle have been especially good. Louise Bonne of Jersey, occupying a position facing south-west, has ripened much earlier than was expected, even making allowance for the extra warmth that has prevailed, but being an old tree about half of the fruits were only of medium size, but highly coloured. Marie Louise, Beurré Diel, and Durondeau, the two former on a south and the latter on a west aspect, have all attained an unusually uniform and handsome size. Muirfowl's Egg, a sure bearer in all sorts of seasons, although not small in size of fruits, is hardly up to the average of moister seasons. Beurré Capiaumont, on a young tree and also on a south aspect, has borne a rather heavy crop of good and evenly sized fruits. As many of the fruits on standards were blown off during the great gale of the 21st of August, I am unable to give further notes on Pears approaching to

accuracy.

In summing up it is unmistakeably evident that as results of the almost entire absence of frost last spring, together with the higher average temperature of the past summer as compared with most seasons, Apples and Pears on comparatively young trees have been extra large, well coloured, and the flavour excellent, also that the produce of vigorous old trees have shown an appreciable improvement in similar respects. The crops of Plums of most varieties grown in the gardens from which I write and also in the surrounding districts have been above the average in total weight, while the quality marks a high order. Soils, situation, and cultural treatment, however, affect the merits of fruits in a greater or lesser degree, and a series of reports only from different localities and cultivators would convey an approximately correct estimate of the fruit crops throughout the country, and of the cultural and climatic conditions upon which they depend. Such reports would no doubt be welcomed by all interested in pomology, including your correspondent.—D. M., Ayrshire.

INSECTS OF THE FLOWER GARDEN.

(Concluded from page 270.)

It may seem odd that in the cheese-mite group, so called, there should be several species which live in the garden, and are mischievous to flowers; yet such is the case, while others of the group are either of predatory habit or they resort to decaying animal substances. Cheese being an artificial compound it is evident that before man made it even the veritable cheese-mites must have found some other animal or vegetable food. As we know that one section of these mites feed upon bulbs, tubers, or fleshy roots, it is possible these may be the natural food of most, but the possession of a sucker by some species, and not by others, indicates differences of habit amongst them. It does not seem that

the cheese-mites change their diet, however, after the manner of their brethren, the harvest-mites, though some of them differ so much in appearance when they are adult that it has been suggested they may be frequently the victims of a parasitic mite of equal size. A good deal of attention of late years has been drawn to one which has received the name of the Eucharis mite, owing to the frequency of its attacks upon this plant; but it does not confine itself to that bulb, nor indeed to others, for I believe there is proof that though seldom noticed, the mite also visits a variety of roots.

If we examine a specimen of what was at first named Acarus Hyacinthi, now known as Rhizoglyphus echinopus, we see a smooth, whitish mite, having a rounded body; both this and the legs are studded with hairs, but those on the back are simple, and those on the legs bristly. The mandibles or jaws are in shape very much like the claws of a crab, and by these they injure bulbs and roots; the head is small, and in walking the mite lowers it between the fore legs. Living, as this insect does, between the scales of bulbs, it remains undetected, often, till the plant is beyond recovery. Boisduval first observed it on the Hyacinth, but many Liliaceous species have been found to be subject to its attacks, and especially in spring and autumn. Probably specimens, young or mature, sometimes lurk in bulbs that are kept in stock ready for planting, or that are transferred in commerce. A peculiar form of skin irritation, which has affected persons who have had to handle quantities of Hyacinth or other bulbs has been attributed to the Eucharis mite. Its occurrence upon roots of the Vine swarming with the phylloxera led to the supposition that this Rhizoglyphus might be a devourer of its relatives under some circumstances, but recent investigation shows it is really a vegetable feeder. Very recent investigation shows it is really a vegetable feeder. likely it often follows in the track of larger insects, and when living underground seeks out roots which have already been bitten, and so obtains their juices more easily. It has been argued that R. echinopus selects for attack bulbs that are already in a condition of incipient disease, and such alone. There appears to be a doubt about this, but either bulbs or roots that are unsound have little chance of recovery when this mite has once assailed them. A variety of applications have been tried; salt is fatal to the insect, but if the solution is of adequate strength it may injure the plants. Watering with a solution containing an ounce of coal tar soap to a gallon of water has been found serviceable, and, as a dry application to the soil some recommend a mixture of soot, lime, and

In conclusion, I have to refer briefly to a large group of mites which have as yet been imperfectly investigated, the exceedingly minute size of many being a difficulty, also their peculiar methods of concealing themselves. We call them the gall-mites, or Phytopti, and one of them, P. Ribis, has attained notoriety by its extensive attacks upon the Black Currant the last few years, and though so tiny an insect it has greatly diminished the crop of fruit in some places. It seems strange that insects so tiny should be capable of mischief to such an extent, but when some hundreds of them are browsing amid the tender leaflets of a bud the result is that the irritation and exhaustion they cause prove fatal to its life.

Less harm is done by those of the Phytopti that live upon leaves; they produce a great variety of galls and swellings, or what looks like a fungoid growth in other instances; and, indeed, skilled botanists and entomologists have both been perplexed by the appearances of some leaves which have peculiar growths, that might pass as cryptogamic, yet are probably due to the agency of a mite. Even with a good microscope the Phytopti are difficult to detect, since they have, though not very active, a peculiar way of shuffling about; also they are transparent or nearly, and soon dry up. It remains a mystery how they manage to distribute themselves over a tree or pass from one tree to another, nor do we know as yet what becomes of the leaf-eating species during the months when trees are bare of leaves. The mites that live in buds can continue their operations in the winter unfortunately, and are probably the cause of more damage than we have yet ascertained.

In their earliest stage many of the Phytopti appear to possess only two legs; observations on the Black Currant and other species have proved they afterwards own six or even eight. With regard to the mouth, their mandibles have been noticed, minute as they are; but authorities are not agreed whether these mites possess a sucker in addition to the kiting apparatus. A few entomologists think the Phytopti may be the young of mites of a larger sort. There is every probability that the Phytopti or gall mites, now that they are being looked after, will be detected upon some herbaceous or shrubby plants in the flower garden; at present they have been chiefly noticed upon trees and bushes. Against those that live upon leaves the only charge is that they act as disfigurers; they do not seem to occur in sufficient numbers to check growth. They are not always found within the galls and swellings they cause;

sometimes they may be seen wandering about the exterior or absent altogether; very often the deserted gall is filled with It is impossible they should infest buds without killing or seriously damaging them, especially when they have commenced operations in October or November. Réaumur, the great French entomologist, who first observed these gall-mites, records his researches after the tenants of the familiar nail-galls of the Lime. These are green while young, then yellow, next red, and afterwards brown. This species is P. Tiliæ; and another very conspicuous species is P. Aceris, the cause of crimson or purple galls which cluster upon the leaves of the Maple and Sycamore. Upon Willows occur a variety of galls, sometimes globular, sometimes flattened; also we have rollings of the leaf edges, evidently the work of mites. The Turkey Oak (Quercus cerris) is apt to be much disfigured by them, so is the Alder; in the Birch the galls take the form of small white knobs on the leaves and stalks. To another species is attributable the curiously deformed clusters of flowers the Ash not unfrequently exhibits. Upon some papilionaceous plants a very tiny species has been detected; the mites live between the unfolded pinnate leaves. It is satisfactory to know these gall-mites are kept in check by larger mites and other insects, which devour them.—ENTOMOLOGIST.

PEACH GROWING FOR MARKET.

(Continued from page 117.)

THERE are several methods of culture open to market growers, but it is doubtful if any pay better than that of planting in the cheap span-roofed houses already alluded to. A 14 feet wide house would hold two rows of trees, one on each side, these being trained up the roof by means of wires 10 inches apart and strained through galvanised wire eyes screwed into the woodwork, so as to bring the wires not less than 9 inches from the glass. Peaches and Nectarines will not stand being planted thickly with a view to having a full crop in a very short short space of time. In a young state they grow rather vigorously, and if hard pruned or much restricted will continue to grow strongly and fail to set or swell good crops of fruit. The best antidote for this evil is to allow plenty of room, a distance of 15 feet asunder being not too much. Maidens are the cheapest, and these not unfrequently quickly overtake and surpass the much pruned and trained trees that may have been planted at the same time. Order or select those moderately strong and well ripened, paying another 3d. each or rather more if need be, for the privilege. Some of the best trees I have were, when first received, the smallest maidens I ever planted, but they started strong enough the following spring and never became unduly gross.

If the houses can be utilised in other ways the planting might be delayed till just before active growth commences, or even till the buds are bursting, the precaution, however, having been taken of procuring the trees in the autumn and laying them in thinly in good soil; otherwise the planting may be done any time during

the late autumn or winter months.

The position being drained sufficiently to suit ordinary crops, there is no necessity for going to any further expense in the matter. Nor ought a very rich border to be prepared. It should be good enough to start them well and to support Tomatoes for at least one season, further assistance being afforded from the surface and added to the soil in front of the trees according as it is needed. If there is a clear course the whole of the ground inside the house ought to be bastard trenched, only a very little, if any, of the subsoil being brought to the surface, and a fairly liberal dressing of half-decayed stable manure, or any other partly decomposed material, including weeds, vegetable refuse, leaves, and such like be forked into the subsoil. To the surface soil, if this is of a clayey nature, may well be added a dressing of fine mortar rubbish, charred soil and refuse, wood ashes and sand, this being well mixed with it. Very light soils would be rendered more suitable for Peach culture by the addition of clayey loam or marl, this being pulverised by being first thoroughly dried or baked, and watered prior to forking it into the surface. Some loamy soils are naturally very poor, or more so than they appear to be, and to these I would add a good surfacing of native guano-that is to say, dried and pulverised sludge obtained from the nearest sewage works. renching cannot be resorted to then prepare holes for each tree, these being not less than 4 feet from the front to the back. In either case prepare the sites or the border, if possible, some time in advance of the planting, in order that the soil may settle down Before planting examine the roots, cutting away any badly bruised and also broken ends, clean cuts healing the most quickly and surely. Do not open small holes for these, setting them in and covering straight ahead with two or three spits of soil, but set the roots on a smooth level surface, covering

with some of the best soil each tier of roots according as they spring from the stem, keeping them up rather than driving them downwards. The roots are only too ready to strike downwards, whereas it is near to the surface where they are most wanted. Keep the collar of the trees, or that part of the stem from which the top-most roots spring, well above the ordinary level of the border, or otherwise the time will soon come when they will be found considerably below the surface. It is the deep root action that most frequently ends in an attack of "yellows," and prevention is certainly better than cure in this as well as very many other cases. If the soil is dry when the planting is done give a watering at the time, but if fairly moist do not water for a few days. During the first year, and till the trees cover the whole of the roof, Tomatoes may be grown extensively in the same house, but their roots ought not to compete with the Peach roots for all the moisture and food going, or the latter will get the worst of it. Tomatoes succeed admirably in 12-inch pots, and this method of culture should be preferred after the first year at any rate.

Lean-to and three-quarter span-roofed houses are mostly erected for Peach and Nectarine culture in private gardens, the trees being trained over semicircular trellises along the front, and up the back walls. These forms of structures, however, are far too expensive for market gardeners to adopt. Thanks to the introduction of very early ripening varieties, neither very snug houses nor the expenditure of much fire heat is necessary in order to have ripe fruit in April or May; but those who have either lean-to, three quarter span, or span-roofed houses at their disposal may turn these to account for Peach culture. If the fronts are not less than 6 feet high, 7 feet is a better height, one-half say being of brickwork and the rest glazed, the plan of training the trees to cross trellises as well as up the back walls if any, may be adopted with advantage. By no other method of arranging the trellises can so many trees be grown to a large size in one house. These cross trellises should be arranged at right angles with the front of the house, and be from 4 feet to 5 feet apart. The framework may be constructed of gas-piping, to this being fastened coarse wire diamond mesh netting, 4-inch mesh answers well, this being continued over the pathway along the back and fastened to the wall. Supposing the borders are formed of good holding loam and other materials added as suggested, a few hundredweight of ground bones not being wasted, there is no reason why the trees should not be planted two to each trellis and back to back instead of only one to each. In this case the wire netting should also be doubled or disposed on each side of the uprights. Once the trellises and back walls are well covered with trees, or, say, in the course of three or four years, extraordinary numbers of fruit can be had from a house in which this plan of arranging the trees is practised. If it fails it will most probably be because sufficient head room is not given, cross trellises being altogether out of place in comparatively low houses.

Standard Peach and Nectarine trees planted in span-roofed houses will produce enormous crops, but only a small portion of the fruit is sufficiently exposed to the sun to colour properly, and badly coloured fruits, as I have previously pointed out, are not wanted. Pot culture is preferable to growing standards, as trees in pots can be frequently turned and shifted about, the fruit colouring well accordingly. All the same I do not strongly recommend pot culture. That capital crops of showy fruit can be had from trees in pots I do not dispute, but it means far more time and labour than most market growers can afford to devote to them. Trees well established in pots and carrying a heavy crop of fruit require a great quantity of water and liquid manure, two and sometimes three waterings in a day being required during very hot weather. A few hours' neglect spoils the prospect for a whole year. At the same time if a fairly large span-roof or other form of high fronted house is devoted to Peach and Nectarine trees in pots, these latter after the fruit is gathered can be placed and kept outside, while a paying crop of late autumn and early winter Tomatoes is grown. Chrysanthemums also do well in such structures.

If pot culture is decided upon the cheapest way to work up a stock of trees is to buy maidens and place these in pots just large enough to hold the roots comfortably, a fairly rich loamy compost, not forgetting to add an 8-inch potful of bonemeal to every two bushels of soil, being used. Drain the pots lightly and well and pot firmly. Supposing this is done as early in the autumn as the trees can be obtained, they need not be housed, but may be kept in the open, the pots being well protected with strawy litter till next spring. They need not really be grown under glass during the following season, but would be all the better for being forwarded with the assistance of a little artificial heat, and might well, therefore, share a house with Tomatoes.—Market Grower.

(To be continued.)

CYPRIPEDIUM CLONIUS.

A PLANT of this exceedingly interesting hybrid was exhibited by Messrs. James Veitch & Sons, Royal Exotic Nursery, Chelsea, at the Drill Hall, Westminster, on Tuesday, October 24th, when the Orchid Committee of the Royal Horticultural Society awarded a first-class certificate for it. It is the result of a cross between C. caudatum Lindeni and C. conchiferum, and as will be seen by referring to the illustration (fig. 58), is a very fine flower. The dorsal sepal is long and pointed, white veined with pale green, as also are the petals, which have tail-like appendages 9 inches in length. The lip is ivory white faintly spotted with reddish brown, and is of a unique character.

LÆLIO-CATTLEYA PISANDRA.

During the past few years Messrs. J. Veitch & Sons of Chelsea have raised many charming bigeneric Orchids, and when exhibited these have usually attracted more than ordinary attention. The same occurred at the Drill Hall on Tuesday, October 24th, when the above mentioned firm staged a plant of Lælio-Cattleya Pisandra. This is a pretty flower, and worthy of the first-class certificate which was awarded on that occasion. It is the result of a cross between Lælia crispa and Cattleya Eldorado. As depicted in the illustration (fig. 60) on page 407 the bloom is medium in size, but exceedingly beautiful. The sepals and petals are of a pale rosy mauve shade, the front lobe of lip being a very rich maroon; and the golden yellow in the throat is a conspicuous feature in the flower.

CATTLEYA MARGINATA.

Amongst the smaller Cattleyas this species is most conspicuous, and its beauty has rendered it a favourite with Orchid growers generally. It is also one of the few Cattleyas that succeed best on blocks, and in this respect it forms a charming companion for the fragrant C. citrina, C. Walkeriana, and others. These, unlike many other species, do not produce good results when in pots, and the peculiar downward-growing habit of C. citrina especially unfits it for that mode of culture. C. marginata is a Brazilian Orchid, and was introduced many years ago. It is now included in most large collections of Orchids, and fairly good plants can be purchased for half a guinea. One reason why it is a favourite is because it thrives in a cooler temperature than the majority of the Cattleyas, a recommendation of great value where highly heated houses are objected to, as they are in many establishments. The cool end of an ordinary plant stove or an intermediate house will suit it, and if attention be particularly paid to the supplying water frequently little difficulty will be experienced with the plant.

The flowers are of moderate size; the petals much broader than the sepals, but, like them in colour, usually a soft rosy purple, the lip being intensely rich crimson, with a narrow margin of white, and a white throat, which contrasts very markedly with the rich coloured portion. These tints, however, vary considerably in depth, brightness, and clearness, and the value of the plant varies proportionally to its merits in these respects. The flowers are usually borne singly from the top of the small bulbs, but occasionally two may be produced, though this is comparatively rare. In many collections it is now flowering freely, and a quality of inestimable value at this time of year when Orchid flowers are so scarce is the great time they last in beauty. Under favourable conditions flowers will remain upon the plants for six weeks, continuing attractive from September till the middle of November.—Specialist.

NEW PICOTEES.

(Concluded from page 383.)

ALTHOUGH an effort has recently been made to abolish this namefor a section of the Carnations, old growers, and indeed young ones too, have shown very little inclination to do so. The designation "Picotee," as a distinctive name for the edged or margined section, has been in use for a great portion of this century, and so let it remain, for it is thoroughly understood. Of the extreme beauty and refinement of this section there cannot be any doubt, and blooms of some of the very best kinds in cultivation, when the dresser's art is not too heavily pushed, are really beautiful. But it is to write of the newer sorts of Picotees that I have set myself, and to the uninitiated I may say that all in this section have a body of colour of white, ivory white, as pure in colour as possible,

and free from small spots of colour or minute bars or elongated spots and the margin, whether light, medium, or heavy, of one shade only.

NEW VARIETIES.

Boadicea (Thomson).—Heavy purple edge. A very good flower, of medium size, with broad petal, and clear ground colour.

Dr. Huxley (Thomson).—Medium rose edge. A refined flower of appellant forms.

excellent form.

Esther (Geggie).—Light purple edge, good size, broad petal, clear white ground, with bright edging. One of the best of its class.

Heroine (Sharp).—A heavy bright cherry rose edge, very distinct in

colour. A handsome flower, with pure white ground colour.

Lady Alfrida.—A Clara Penson style of flower but finer, with an

excellent petal, pure ground colour, and bright wire edging.

Lady Gordon Catheart (Turner).—A light red edge, pure in the

ground colour, fine broad petals, and of good substance.

Lady Emily Van de Weyer (Turner).—Light rose edge, with very broad smooth petal well continued to the crown, good size and of fine form.

Miriam (Bacon).—Medium, purple edge. A splendid flower, clear white with fine broad petals of good substance.

Miss Lakin (Lakin).-Light purple edge, the white pure, of fine

Mrs. Beal (Beal).-Medium rose edge, a very beautiful flower, excellent petal with clear white ground. An improvement

on Fellowes' Ethel, good grower. Mrs. Burnetts (Chaundy).-Medium, rose edging in-

clining to heavy. A large flower and of fine quality. Mrs. Openshaw (Geggie).—Heavy purple edge, fine broad petal, clear lustrous white ground with bright edging. A flower which gives a promise of a high position in its

Madeline.—Rose edged, very fine broad petal and good

form, but rather thin as seen about Birmingham.

Ne Plus Ultra (Lakin).—Pure white ground colour with a very heavy red edge, fine form, good substance, the darkest heavy red edge. An extra fine flower.

Polly Brazil.—A splendid flower, pure white with bright heavy purple edge. One of the best in class.

Pride of Leyton (Headlands).—Light distinct purple

edge; a flower of good size, broad petal, and lustrous clear white ground colour.

Rosie Sydenham (Sharp).—Pure ground colour, with a superb broad petal of great substance, and a flower of very fine quality; medium light rose edge.

Souvenir de Headland (Headland).—Light rose edge;

a large bloom, clear white ground colour, but a feather edge flower.

Scarlet Queen (Sharp).—This charming flower is best described as a bright scarlet edge Mrs. Sharp, but un-

fortunately the stock is very limited at present.

Mrs. Herbert (Thomson).—This variety has maintained its character for refinement; a beautiful flower, but not

large. Other new sorts which I have not seen are being sent out by Mr. Dodwell, who speaks highly of Mrs. Lovatt especially, by Mr. George Chaundy and others. Information regarding these can be found in their catalogues.

YELLOW GROUND AND FANCY VARIETIES.

What a wonderful improvement in these during the last few years. Mr. James Douglas has introduced many fine varieties of his own raising, and Mr. Dodwell has also contributed a large number, and other English raisers are at work. Then Mr. Benary, and other eminent

German florists, have been devoting much attention to the Carnation, and have introduced varieties of sterling merit and distinctness, and these glorious fancy varieties are becoming very popular. In the "Florists' Guide" for 1827-1829 there is a coloured plate of what in those days must have been a fine yellow-ground fancy variety named Erasmus, and it is described as having been previously imported from Germany by the celebrated old florist, Thomas Hogg of Paddington Green, London. It is referred to as one of the finest varieties on account of It is referred to as one of the finest varieties on account of its rich colours and its broad, Rose-shaped petals, so that the German florists are not novices in the raising of fine yellow-ground varieties. I may say that in fancies Carnations and Picotees are getting very much mixed, as flakes and stripes run down the petals in some kinds, and the distinctive fine edging of the florists' Picotee is so little met with in some varieties, the Continental ones especially.

Brand von Hamburg.—A medium-sized flower, orange ground colour, with bright orange scarlet markings, smooth petal, and an acquisition.

Calypso (Benary).—Of dwarf habit, rich coloured clouded crimson and maroon, with a lighter colour at the base of each petal. A very distinct, rich coloured flower, of good form and substance.

Celsius (Benary).—Old gold colour, flaked with scarlet, fine and

distinct.

Duchess of Portland (Simonite).—A large flower with broad petals, pale yellow ground colour with mauve edge, and a free bloomer.

Eclipse (Simonite).—Large size, good form, and petal, rich creamy yellow ground with bright scarlet edge, and slightly striped with the same colour.

Crayon d'Or.—A distinct flower, primrose, distinctly lined with pale scarlet, and remarkable for its strong clove perfume.

Elmis.—Pale primrose barred with lilac and orange. A very distinct flower of good quality.

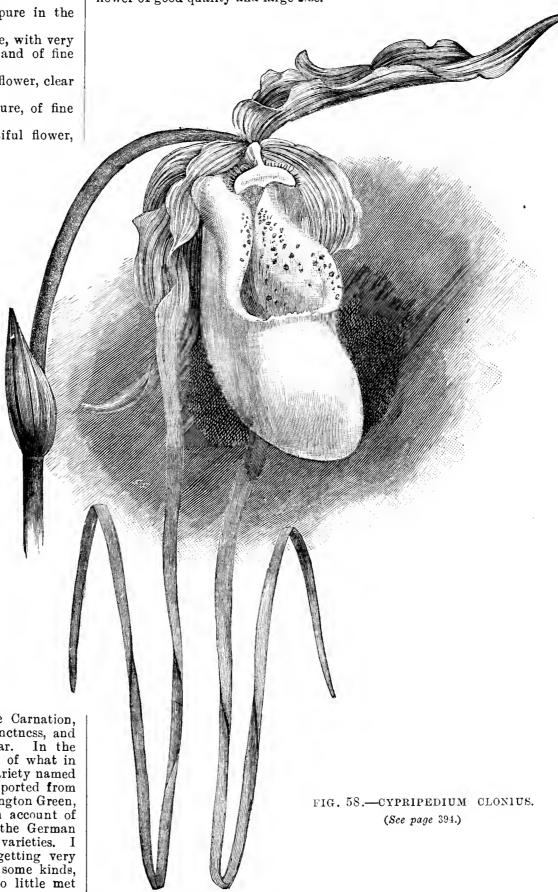

Fri drich Wagner (Benary).—Lemon, barred with light brownish lilac. A distinct fine flower. JIA?

Fanny Trommsdorff.—Blush tinted, white ground, striped half way down the petal with lilac purple. A grand bloom with fine petals.

F. A. Haage (Benary).—A very novel flower, creamy buff ground distinctly flaked with carmine and slate and of good form

Golden Rain (Douglas).—A large full flower of excellent form, buff ground colour suffused with bright red. Very distinct and pleasing.

Lohengrin (Benary).—Primrose, barred with rosy carmine. Affine flower of good quality and large size.

Mrs. Henwood (Douglas).—A beautiful light yellow-ground flower with bright scarlet edge and good broad petal. A decided acquisition.

Moltke (Benary).—Deep yellow with heavy red edge. Quitc an acquisition and distinct.

Miss Gilmore (Simonite).—Pale cream ground with rosy mauve edging.

Mrs. Robert Sydenham (Douglas).—The finest of all the yellow ground varieties. The colour is a rich creamy yellow with bright rose edging, with fine petal and of great substance. A superbly brilliant ground varieties. flower of the finest quality.

Mrs. William Spencer .- A seedling of Mr. Herbert's, best described as a fine companion variety to Mrs. Robert Sydenham. Primrose yellow ground with a Picotee edging of mauve purple, and in every way an extra fine flower.

Parsiful.—A German variety of a rich rose tinted chocolate colour with a lemon base in each petal, of large size and very fine quality; a great acquisition and quite distinct.

Queen Boadicea (Simonite).—Bright light yellow ground with wire

edge of bright scarlet, slightly barred; a pretty flower.

Rosalinde (Benary).—Beautiful deep yellow ground colour with a medium Picotee edging of rosy purple, a very attractive flower, and has been greatly admired.

Undine (Benary).—White ground, barred half way down the petals

with greyish rose; a large and very distinct flower.

Von Benningsen (Benary).—Although not quite new it is as yet very little known; brilliant in colour, orange ground marked with brightest scarlet.

William Dreer.—Very bright rich salmon tinted ground colour with

carmine markings.

It will thus be seen by the list I have given that there is almost a plethora of new varieties, although several of the German varieties of 1893 are passed over. I have seen all those described above, out there are still several other fine kinds being introduced. Mr. Dodwell has some, and Mr. Douglas, Mr. Turner, Mr. Chaundy and others have new kinds which I have not seen. It is quite evident that our English florists are well ahead in hybridising and raising, and that other very fine varieties are forthcoming. Some varieties, both old and new, will have to be thrown out of collections, for not one cultivator in a hundred could give time and room to so many new sorts as I have named, in addition to the best older favourite varieties. In Mr. Turner's stand at Birmingham there was a fine yellow-ground variety named Adelé, pale cream edged with scarlet; and Miss Proctor, creamy buff striped with bright scarlet, both fine.

In selfs Rose Wynne has fine petal and form; Rose Unique, bright light rose, fine broad smooth petal and of very fine form; King of Scarlets is an extra fine bright scarlet; and Justinian, a lively light pink self, is pretty, but is not turning out to be an acquisition.—W. D.

HYBRID BRIAR ROSES.

Is Mr. David K. Williamson as accurate as he usually is in his statement (page 384) that Lord Penzance's hybrids are from "the wild Roses of the woodlands?" I do not know whether the Sweet Briar comes under this poetical description, but I believe Lord Penzance's hybridisation experiments have been mostly, if not entirely, in connection with the scented variety of the Briar. I understand these hybrid Sweet Briars will not be distributed till the autumn of 1894, so it will be some time before rosarians will be in the possession and enjoyment of them. Their names will please the Scotsmen, as they comprise such celebrities as Amy Robsart, Anne of Gierstein, Lucy Ashton, and other well known heroines of the Wizard of the North.—Charles J. Grahame, Croydon.

AUTUMNAL ROSES,

EVERY Hybrid Perpetual Rose should bloom well in the autumn to be worthy of its name. Nevertheless it cannot be denied that there are many admirable varieties, supposed to be perpetual, which, during the months of September and October, produce an insignificant number of remarkably small-sized blooms. In the summer they are exceedingly prolific; probably at that period, inspired by the strong sunlight, they attempt too much; in the autumn they have the aspect of having been utterly exhausted by their previous exertions. Charles Lefebvre, for example, which produced in July a succession of truly magnificent Roses, bloomed during the autumn with manifest difficulty; his Lilliputian productions could only be regarded as lamentable miscarriages by those who had witnessed his earlier achievements. The cool season, so eminently favourable to the preservation of his complexion, deprives him of half his normal strength. On the other hand, such varieties as the Pride of Waltham, Crown Prince, Ella Gordon, Magna Charta, which is, like its namesake, a "perpetual" possession; Prince Arthur, and his venerable parent Général Jacqueminot, Mr. Cranston's Crimson Bedder, likewise La France, Victor Hugo, and Augustine Guinoisseau, have been of late in my own garden remarkably fine.

have been of late in my own garden remarkably fine.

The largest individual Rose I have seen this year I found blooming yesterday (October 20th) on Baroness Rothschild. Had it only been fragrant I would have attached more importance to its splendour of colouring and marvellous dimensions; but the imperial Rose in question is scentless. The same applies to the White Baroness and the stately Merveille de Lyon. Magna Charta, described by the Dean of Rochester as almost a summer variety, is, nevertheless, according to my own experience, a splendid autumn Rose, and as much may be asserted of that veritable Queen of the Hybrid Perpetuals, Mrs. John Laing. But from this special point of view by far the most valuable Roses are the Teas, particularly such specimens as Ernest Metz, Comtesse de Nadaillac, Hon. Edith Gifford, Marie Van Houtte, Etoile de Lyon, Perle des Jardins, and Belle Lyonaisse. In power of productiveness

even the most prolific of the Hybrid Perpetuals must suffer considerably when compared with these. How beautiful, beyond all artistic delineation, are their infinitely varied, yet marvellously harmonising hues! In them the evanescent colours of the rainbow, of the sunrise and the sunset, are gloriously combined.—DAVID R. WILLIAMSON.

Rose Analysis, 1886-1893.

MR. GRAHAME says that he is a "business man." But surely it is a very unbusinesslike proceeding for one man to condemn the work of another in such a high-handed and reckless fashion as he has mine (page 384) without adducing a single particle of evidence in support of the theory he has advanced against it. Mr. Grahame asserts that the crude figures should rule the analysis throughout. But this only shows how little knowledge he has of even the elementary principles which should guide anyone dealing with facts such as those I had at my disposal for the purposes of my last Rose analysis. For instance, I take up the first work of reference that comes to hand, "Chambers' Encyclopædia," and at the end of a short article on "Statistics" I find the following appropriate words of caution, "The frequent connection of statistics with political theories renders it important to guard against premature statistical conclusions, of which two very fertile sources are calculations from an insufficient number of data, and neglect to make allowance for disturbing causes."

Had Mr. Grahame been specially trained, as years of meteorological work have trained me, for this particular kind of investigation, he would know that there is a very great difference indeed between making due and proper allowances for such disturbing causes, and altering facts to suit preconceived theories as Mr. Grahame clearly infers I have done. It is, I conclude, owing to his inability to appreciate the wide distinction between these two methods that he fails to understand the serious nature of the charge he has made against me.

The fact is, what is wanted above everything else in all investigations of this character, is not so much the actual figures themselves as that the results given should be made as comparable as circumstances will allow. Now I have no theories whatever of my own which I wish to thrust upon the readers of the Journal of Horticulture in framing these analyses, my only object being to make the materials at my disposal tell their own tale. This they would fail to tell truly in many cases owing to the disturbing causes mentioned on page 358, but fair and impartial allowances having been made for them, the averages when calculated are considered ready for insertion in the printed analysis. If I were to give in every case the crude results I should not be guiding, but on the contrary be often misleading your readers.

Mr. Grahame considers that had I more data each year to go upon the results would come out differently. Possibly this might be the case to a certain extent, but so consistent are the records from year to year that I cannot think the relative positions of the different varieties in the tables would be in any way seriously affected. Moreover, there are several grave objections to adopting such a course now. In the first place the data would not be obtained entirely from the same unexceptional sources—only prize stand blooms being now admissible. Then, again, the records would not be strictly comparable with those secured under the system adopted during the past eight years. Besides which I am afraid I should have to give up the work altogether through want of adequate leisure to carry it on satisfactorily. Looking as impartially as it is possible for a compiler to do upon one of his own bantlings, I must say I cannot help feeling proud of this last Rose analysis of mine. 1, The sources from which the data are obtained are beyond question, being the unconscious contributions of all our leading rosarians throughout the country. 2, Now that I have comparable results for eight years before me I begin to see how the figures obtained each year support and confirm one another. This, indeed, is my greatest source of satisfaction, for had my method of analysis been unsound this could not possibly have been the case, considering the different dates at which our National Show is held, and the varying nature of Rose seasons.—E. M., Berkhamsted.

[Mr. Mawley's records, on which the results as representing the actual relative differences in value of the varieties enumerated, have been submitted to us, and we are able to say that the conclusions arrived at are not founded on individual fancy, but on actual figures, these figures representing accomplished facts; the final issue, therefore, though it may appear arbitrary, is mathematically correct as deduced from the compilations over a series of years. One of the leading statisticians in London has also examined the records, and he finds the deductions from them are true according to the elaborate and, we must add, laborious system adopted in their preparation. We have no hesitation in expressing our appreciation of the painstaking manner which Mr. Mawley adopts in the preparation of his valuable analyses as applied to Roses, Chrysanthemums, and Dahlias.]

ROSES AND OYSTERS.

It may seem a far cry from Roses to oysters—from the choicest gems of earth to the most valued treasures of the ocean. Certainly some Roses are said to have shell petals, and both Roses and oysters require a well regulated supply of water, although neither may care to drink the special beverage of the other one, otherwise they would appear to have no resemblance or tastes in common. However, when attending the Mayor's oyster feast which was held with all due pomp and ceremony in the Corn Exchange, Colchester, I had an opportunity of judging how under certain favourable circumstances it was possible for

them to become almost inseparably connected, for on that occasion the guests were said to have consumed about 10,000 oysters, while the tables had been most tastefully decorated by the ladies of the district with no fewer than 4000 Roses. As the President of the National Rose Society, the Dean of Rochester, remarked in the course of a most entertaining after-luncheon speech, "He supposed there never was an occasion in which there was such a combination of things pleasant to the eye and good for food as there was that day—a combination of Roscs and oysters." He said, "Well might the early Britons turn their backs on their acorns and flock to Colchester. Well might the judicious Roman bring his camp and plant it by the side of the Colne. Well might the Saxon, the Dane, and the Norman come and settle down at Colchester. Kings and great generals had fought battles for Colchester.

Why, then, the world's mine oyster, Which I with sword will open.'

"Well, too, might those great ecclesiastics, the Abbot of St. John's and the Prior of St. Botolph, alleviate their days of abstinence as they alleviated them that day."

I only arrived at eleven o'clock in the morning, and the feast was fixed for two o'clock in the afternoon, but I determined to make the best use of the three hours at my disposal, for I thought I could not well come to Colchester without giving myself the treat of visiting the nurseries of the two Cants. As these are both about a mile from the station, and more than two miles apart by road, and also about two miles distant from the Corn Exchange, I had little time to spare for either nursery. However, I did manage to see and learn something, and had the still greater pleasure of a chat about Roses with representatives of each firm.

The plants I saw, both dwarfs and standards, notwithstanding the dry summer, had made excellent growth; but it was piteous to behold the gaps in the rows of the latter, so many stocks having been killed during the trying winter of 1892-1893, owing to the frost setting in so early in the season, and the dry spring which followed. There were no flowers to be seen, as every bloom worth looking at had been cut off and carried away hours before to decorate the Corn Exchange. But there were the plants by thousands with splendidly ripened shoots looking as

if ready for removal to their new homes at a moment's notice.

I was always under the impression that all the soil round Colchester was of a heavy retentive nature, but much that I saw in these nurseries was a comparatively light loam with a certain amount of sandstone grit It is in such soils that fibrous roots are encouraged, and I was told that the plants become more quickly established in these quarters than where the soil is heavier. I happened recently to find this out in my own garden at Berkhamsted, where the soil is composed of yellow clay and flints, and where Rose plants take a long time to get hold of the ground, but when once established make great growth. Last autumn I had occasion to move about a hundred dwarf H.P.'s, and thought I would try the plan of using when replanting them some gritty soilturfy edgings cut from the roadsides—to place about their roots. This plan has answered so well that the plants in question have already in less than a twelvemonth become as strong as I could wish to see them. When amateurs receive plants which have not extra strong shoots from the nurseries, they are, I find, invariably disappointed. This is, however, a great mistake, for it is the plants of moderate growth, I do not mean "starvelings," which have well ripened shoots and fibrous roots, like those I saw the other day at Colchester, which will become established most readily, and therefore thrive best in their gardens the following season. On receipt of such plants do not expose their roots to the drying action of the atmosphere a moment longer than is absolutely necessary. This is an oft-repeated injunction, but how seldom in practice is it followed! Place some light fibrous soil, if obtainable, above and below their roots, and plant firmly. By using such soil as I have recommended they may be put in the ground satisfactorily, even when the rest of the bed is too wet for the operation. Afterwards secure the shoots to a firm stake, so that they may not be shaken by high winds. How often do I hear Rose nurserymen blamed for sending out bad plants when after all the fault rests entirely with the bad planting of the purchaser.

Another thing I learnt at Colchester was that the demand for what the N.R.S. catalogue calls "garden Roses" is on the increase. The individual flowers may not be so perfect as those of the exhibition varieties, but their colours are often most enchanting, and many of them are extremely free-flowering. I asked why standards were always in such request for suburban and other small gardens when dwarf plants were so much cheaper and more lasting? I was told that the owners of these gardens invariably replied that when they had a few standard Rose trees there was something to look at when they come into flower, but as to the dwarfs they become hidden away among other plants in the summer, and so were never seen. These suburban and other gardeners should learn once for all that the queen of flowers will brook no rival, and that, therefore, it becomes imperative to provide a special bed however small for these bush Roses. Both nurseries are situated on rising ground, and this accounts for their comparative freedom from spring frosts. Coming from a colder and harsher climate I was particularly struck with the even blankless rows of dwarf Teas the result of last year's budding. There were two Teas, however, which I noticed had suffered considerably at all events on the standards, and these were Perle des Jardins and that charming sport from it Sunset, the latter a most delightful variety, as I well know under glass.

I had not time to see the Roses in pots at Mr. Benjamin Cant's nursery, but I did manage to glance through the new Rose house at Braiswick.

I can only say that better plants I have never seen. Mr. Frank Cant was able to set up such charming boxes of cut blooms at the Drill Hall, Westminster, last spring. I noticed that on these occasions the visitors, more especially the ladies, invariably deserted the beautiful Orchids and other exhibits in order to crowd round these Rose boxes. After all there is no flower like the Rose. I do hope Dr. Wallace, the champion of the Lily, whose acquaintance I had the pleasure of making at Colchester, will not notice this last hackneyed remark of mine. Should he happen to do so, perhaps he will be good enough to understand that I only meant that there was no other flower precisely similar to the Rose. The two most vivid impressions left on my mind by my hasty scramble over the Colchester hills were the fine pot Roses at Braiswick and a quarter of grand standard Teas at the nursery of that veteran Rose grower Mr. Benjamin Cant. The Colchester people are justly proud of their oysters, but after all the real "natives" of the district are to my mind the Roses. Nowhere else, of the district arc to my mind the Roses. Nowherc else, considering how limited is the area covered by the three leading Colchester nurseries (for that of Messrs. Prior & Sons, which I should much like also to have visited, must of course be included) are Roses so largely grown. The only wonder is that there are not more amateur exhibitors in this fertile district. I only know of one (Mr. O. G. Orpen of West Bergholt), who from his small garden shows Tea Roses so brilliantly as to excite the envy and jealousy of all competing against him, including the writer of this somewhat rambling contribution.—

VEGETABLE CULTURE IN ADVERSE SEASONS.

(Concluded from page 263.) CELERY.

This vegetable must not be neglected when in the seed bed by allowing the soil to become too dry, or the plants will late in the season have hollow stalks, or seed prematurely. Sow the seeds in shallow boxes, with decayed manure placed upon the drainage. Raisc the seedlings without bottom heat if possible, and when the plants have produced a second rough leaf, prick them in good soil in boxes or frames with drainage similar to that provided for the seed boxes. Never allow the plants to flag, but grow them steadily without undue forcing. Have the trenches ready long before the plants are to occupy them. Previously to planting in their permanent quarters another transplanting must take place. Select a position with a hard bottom, put manure in first, then 3 inches of rich soil, make it firm and plant therein. They will remove from this position to the trenches with good balls of soil adher-

ing to the roots and the growth will not be checked.

Trenches in the ordinary sense I do not believe in, for such often means starvation to the plants during the remainder of the season. How can the plants be expected to flourish when all the best soil is taken out, and they are put into the cold subsoil? The trenches ought not to be more than 6 or 9 inches deep, and if the soil be not of a good general depth I prefer to plant on the surface. Some decayed manure should be dug into the trench and well mixed with the ground, a little loose soil afterwards placed over it. When it is dry tread all down firmly. The trenches may be made wide enough to hold two rows of plants if so needed, but one row is preferable. Attention to watering is necessary, and a light mulching may be given them. Those who have not yet tried the plan of growing Celery on the level ground would do well to test it. I have done so for several seasons, and always in the same place. The ground was made very firm, then planted, and the plants watered regularly, liquid manure being applied every week, and a mulching of manure placed on early in the season, the plants soon required staking, but the growth was solid. For exhibition purposes a few plants treated in this way will give pleasure to the cultivator.

Earthing up is often begun when the plants are 9 inches or 1 foot high, and from that time they suffer through want of water, because it cannot get at the roots. Earthing does not make the plants grow. It is done to blanch the stalks, and from six to eight weeks before they are required for use is soon enough for the first earthing to be done, previously giving a copious supply of water. Some growers use paper, but slugs get under this and eat the stems, making them unsightly. A few ashes and sand mixed placed next to the plants, following with the ordinary soil, is all that is required. All suckers and split leaves must be taken off. Sutton's White Gem and Sandringham White for early use, with Sulham Prize Pink, Major Clarke's Red, and Standard Bearcr for late use, are the best varieties in my opinion, and I can strongly recommend them.

DWARF AND RUNNER BEANS.

Runner Beans require much the same treatment as do Peas, but avoid sowing too soon. The seeds should be sown in an irregular line in the drill quite 9 inches asunder. This is not too far apart, as the plants fill out very quickly when well grown. Dwarf varieties ought to have the same space allowed them, crowding of the plants being not conducive to a full crop. An amateur once saw some I had planted after the manner described, and wondered at the waste of ground, but when he afterwards saw the crop he was more surprised, and said he should not in future sow so thickly as he had done. If the ground is rich, and the plants grow freely, it is advisable to place a few short branching sticks to Dwarf Bean plants, as by so doing straight even pods are produced. which could not be if the plants were lying on the ground. No doubt some of the newer varieties of Runner Beans are acquisitions, and decided improvements upon most of the old kinds during some seasons; but such sorts as Neal's Ne Plus Ultra and Scarlet Champion are to be depended upon. Of Dwarf varieties few are better than Canadian Wonder and Ne Plus Ultra.

LEEKS.

March is the best month in which to sow seeds to produce Leeks for ordinary uses, but for exhibition the first week in February is the most suitable time. Sow the seed in boxes, and treat the plants similarly to Celery. In light soil it is advisable to plant in well manured trenches, but on very stiff soil plant on the level ground. Treat this crop generously, give copious waterings of liquid manure during the summer. Plant deeply, earth up to blanch like Celery, giving a good drenching of water first. Sutton's Prizetaker is a good variety, mild in flavour, but, according to my experience, sometimes liable to soft growth; perhaps the fault lies in the soil only. The Lyon is not surpassed.

VEGETABLE MARROWS.

These have certainly been very plentiful this year. Our plants have been grown in mounds of soil surrounded with plenty of old leaves upon which the shoots have lain. They were poor plants when first put out, but by shading from the sun for a short time they soon began to fruit, and a constant supply has been forthcoming. The seeds should be sown in April, plants duly potted as required, and planted out the end of May or beginning of June on beds which contain plenty of rich soil. During dull weather it is advisable to fertilise the flowers. Moore's Vegetable Cream is the best Marrow that I have grown.

Before concluding, I would like to say a few words about these vegetables for preparing and exhibition and staging them. Good produce may be almost spoilt by slovenly staging. Selection of the different varieties is the first consideration, and mere size is not always to be relied upon. If possible, everything should be had when at its best. Do not forget to use the fork when lifting roots. Do not scrub them with a hard brush, but soak them in water, and use the sponge only to remove the dirt. Select Cauliflowers before their heads open, or they will be partially spoilt. Cucumbers and Vegetable Marrows should be as even in size and as faultless as possible. Carrots ought to be a good colour, and Turnips not too old or stringy inside. Peas must be young and tender, and Potatoes even in size, as nearly eyeless as possible, and clear in the skin. Use plenty of Parsley in staging. Stage in such a way as will show up each dish separately, and to the very best advantage. This applies in the case of a collection being arranged. There is some art to be displayed in arranging a fine collection of vegetables. Separate dishes call for the same care and attention. I should like to take this opportunity of advocating that space be liberally given, as is generally done by societies, on the bare tables, and the entire abolition of trays in the case of collections of vegetables.—Geo. Garner.

PRACTICAL DINNER TABLE DECORATIONS.

[By Mr. H. Dunkin. Read at a meeting of the Ealing Gardeners' Improvement Society.]

I HAVE prefixed the title of this paper by the word "practical," because many styles of dinner table decorations in vogue at the present time, such as one sees at exhibitions, are not practicable as far as the majority of gardeners are concerned. This statement I feel sure will not easily pass unchallenged unless I am able to advance sound reasons to justify so emphatic an assertion. I will therefore attempt to do so

before proceeding further.

The reason why we see so great a disparity between the styles and arrangement of dinner table embellishments at public exhibitions and those carried out in the homes of the wealthy, is to a great extent due to the fact that those who carry out the former select with great care the glasses and stands employed for arranging the flowers in, and in some instances have them specially made for the purpose, while gardeners in the majority of private places have to adapt their floral arrangements to the incongruous and generally far too massive epergnes, stands, bowls, and baskets which are provided. These are in many instances ancient and costly ornaments of gold and silver, works of high art in themselves, but not well fitted to enable the decorator to show his ability in devising and carrying out artistic arrangements which are in accord with the advanced and refined taste of present times. These elaborate ornaments are frequently heirlooms which have been handed down through many successive generations, and are in consequence highly prized by those ancient families who still retain them, and who are as proud on befitting occasions to display them before their guests as they are to show the floral gems of their garden or the artistic ability of their gardeners, who, in reality, only reflect the good taste of their employers. I maintain, therefore, that real ability in this kind of work is best shown by choosing the most suitable materials at command for each individual set of ornaments, and arranging them so as to obtain a good effect without paying too much regard to conventional style, always making a point to have some special feature in each attempt, some feature which will strike at once each beholder, and by it be afterwards remembered. It is, I think, scarcely necessary for me to add the prominent feature should be one which does not offend eyes well trained to a due balance between accurately proportioned forms and well blended colours.

The old method of using a considerable variety of colour at each attempt is now almost extinct, and in many of the best decorations now carried out only one colour is used in addition to that supplied by

the greenery. Speaking generally, white may with advantage be added to almost any combination. When, however, a series of dinner parties are held which necessitate extensive decorations, it is policy, on several occasions, to keep to one colour only, without even the addition of white. A more varied effect may in this way be produced with a given amount of materials than can be secured by any other means which I am aware of.

In selecting flowers for the purpose care should be taken to use only those which look well when seen under the influence of artificial light, unless, as is rarely the case, dinner is partaken of by daylight. The various shades of pink, rose, and scarlet are, I think, more telling under artificial light than any other colours or shades of colour; certain it is that when well executed designs in which either of these colours—especially the two first-named are employed, they command universal and, in some instances, enthusiastic admiration. Dark blue and purple flowers should invariably be avoided, but pale blue ones often look exceedingly pretty when arranged with soft yellow flowers or foliage, or when yellow coloured silk is laid upon the cloth. I have frequently heard and read that yellow flowers are not effective when seen under artificial light. Some shades may not be, but I can scarcely imagine how we could well dispense with the fine clear yellow and bronzy yellow shades of Chrysanthemums, which have a peculiar and delightful beauty of their own, and are, moreover, especially adapted for dinner-table embellishments. Simple rules as to which colours harmonise with each other are useful to beginners; but those who have a correct eye for colour should rely solely on that gift to guide them in the art of colour-blending. They will then be able to work out many exquisite combinations of colour, which those who rely principally upon a dogmatic code of rules can never imitate without running great risk of offending the more correct and sensitive optical organs of those with a good eye for colour. When there is any doubt as to the appearance the colours intended for more there is any doubt as to the appearance the colours intended for use will present under artificial light, the point may easily be settled by taking the various flowers into a darkened room to examine by the light gas or lamp.

Every gardener who has had a fair amount of experience in the arrangement of flowers for whatever purpose, is aware that a light feathery outline must be obtained to produce a good effect. It is therefore essential that crowding should at all times be avoided. Some fail in securing this lightness of arrangement, because they experience considerable difficulty in fixing the flowers in the exact positions they require them to occupy. This is, however, easily accomplished by inserting pieces of box a few inches in length between the stems, so as to keep each flower held firmly in position. When each glass or stand is filled I like to look it carefully over, and should there be any appearance of overcrowding remove a few flowers by cutting the stems asunder at the water level; this is far better than pulling them out, as there is no danger of loosening and disarranging the others. Simple though this matter may appear it is well worthy of attention. In almost all arrangements it is important to have a good proportion of small light flowers cut with long stems, such as Spiræas, Oncidium flexuosum, Masdevallias, Epacrises, Cornflowers, Gypsophila paniculata, and a host of others possessing similar characteristics. When only medium sized glasses are used flowers of a heavy nature are quite out of place except in the case of those which have a dish-like base. Where, however, massive stands or epergnes are used, flowers of a bold type, so long as they are thinly arranged, should be used.

STYLES OF ARRANGEMENT.

Fashion in this, as in all other kinds of decorative work, is continually changing; but whatever the prevailing method of the day may be various other styles also must be frequently brought into use whenever a series of dinner parties take place, otherwise monotony is painfully apparent. I have sometimes noticed on such occasions that a method of arrangement practised twenty years ago will, if worked out in the lightness and finish which commends itself to modern taste, and secure enthusiastic admiration. Tracing, for instance, is not nearly so much in vogue as it was ten years ago, yet if well done it is extremely effective; but then we use things which I consider are far better adapted for the purpose now, which may have much to do with its continued popularity. Coleus leaves laid so as to overlap each other were at one time freely employed, but to my mind they are much too flat and formal looking. Sprays of Honeysuckle, Weigela rosea, or small pieces of the feathery Retinosporas, represent after more effective type of material.

At this season of the year, when there is plenty of coloured foliage to be had, a simple but unique arrangement may be made by covering the whole space available on the cloth with autumn foliage of several tints. Berberis aquifolium answers the purpose well. The points of shoots as well as single leaves should be used, because they will take off the flatness. A glass or epergne dressed with flowers and Fern should then be placed in the centre, and two smaller ones on each side if the size of the table requires them. White flowers arranged in little irregular groups wherever room can be found for them, with a Fern frond added here and there complete the arrangement, and if the work has been well carried out the effect produced is strikingly effective. Tins made 1 inch deep, 1½ inch wide, and fitted in a continuous design round the table, if filled with sand and arranged with Maidenhair Fern, small trusses of Pelargoniums, Chrysanthemums, or other flowers, look very pretty. The effect is still better if sockets are made in the tin at intervals of 2 or 3 feet, so that small glass trumpets may be fitted into

the sockets and arranged with flowers. A dressed stand in the centre with a Cocos Weddelliana on each side, will render the whole light and quite imposing.

Very pretty plated glass ornaments set in silver are now made in the form of baskets. Some of these have glass pendants, and glass chains to connect one basket with another. Some of the most beautiful dinner tables I have ever seen have been made so by using these baskets. A table to seat about fifteen is a suitable size to secure good balance. The largest basket dressed with flowers should be placed in the centre, having a few long pieces of Smilax (Myrsiphyllum asparagoides) trailing over the sides and along the table. Next will come two candelabra, then two smaller baskets filled with flowers; eight still smaller ones are then placed around the sides of the table, the four corner ones being arranged with small Ferns of various sorts knocked out of 60-sized pots; the other four having a small Cocos Weddelliana in the centre, with flowers and Fern fronds arranged at their base.

Various other methods of arrangement might be given, but I think enough has been adduced to serve as a foundation, upon which an infinite variety of combinations may be worked out by those of an ingenious turn of mind. I will therefore conclude by giving the outline of a design which is especially adapted for use during the Chrysanthemum season. In this case no stands, glasses, or epergnes of any description will be required. First cover the centre of the table with thick brown paper, then cut the outer edges of it into a series of serpentine sweeps, so as to avoid formality in outline. In the centre, on an inverted pot, place a plant of Pandanus Veitchi or one of Phœnix Next will come two candelabra, these to be followed by two graceful plants of Cocos Weddelliana, and two smaller plants of Pandanus will be suitable for the two ends. Now cover the whole of the brown paper with fresh green moss, and raised mounds of it to cover the pots used. If the table is a rather wide one very small Palms of more graceful kind may be dotted about here and there in each case, making a tiny mound to cover each pot. Next trace round the outer edge of the moss with some kind of coloured foliage, and the most troublesome part of the work is completed. The remainder consists in dotting Chrysanthemums, both large and small, at irregular intervals all over the moss, of course avoiding anything approaching crowding. Some of the Japanese kinds which have drooping petals should stand well above the moss, so as to display their fantastic beauty to the best advantage; this can easily be done if the stems are sharpened and thrust into the moss, an extra depth of which may be given at such points. Fronds of Maidenhair and Pteris Ferns and a few small whorls of Cyperus alternifolius inserted here and there give a finishing touch to the whole. Anyone who has the opportunity to carry out this arrangement will, I am sure, be delighted with it, and the guests when seated round the table will find their eyes resting upon a scene which, for a moment, might take them in flights of fancy to the realms of fairyland.

FLORAL NOMENCLATURE.

OBSERVING a remark on page 384, about the much-discussed pronunciation of the word Gladiolus, may I briefly sum up all that ever has been or can be said about it? It is a general law of pronunciation that you cannot speak a word in which three short syllables occur together without accenting one of them. Hence a word of six short syllables must have two of them accented, as Měsopotamia; but a word of five short syllables only requires one to be accented, provided it is in the middle, as Măcedonia. In words of four short syllables such a pronunciation is, as "W. R. Raillem" (page 384) says, practically impossible. A classical scholar from Oxford or Cambridge would naturally say Glădiolus, modiolus, following the ordinary habit of pronouncing the words in Latin. There has been, however, an attempt in English to turn these words into trisyllabic words, by pronouncing "i" as "j," and saying Glādjölüs and mödjölüs; this, however, is a modern conceit, which I hope will not prevail.—C. Wolley Dod, Edge Hall, Malpas.

P.S.—The suggested compromise between "i" and "j" leaves us a host of words, like měděola, mědícia, and polygala, which cannot be dealt with in the same way.

CURIOUS SPELLING OF THE NAMES OF FRUITS AND FLOWERS AT SHOWS.

THE note by "East Anglia" (page 375) reminds me that I too have some memoranda on the above-named subject, and now that the autumn shows are coming on perhaps a few friendly remarks will not be out of place, and may help towards an improvement in the spelling of the names of fruits, plants, and flowers. That it does not receive the attention it deserves is only too evident, as anyone may easily learn if he will take the trouble to look along the tables at a flower show. I have often been surprised that some exhibitors arc so careless on this point. It seems to me a pity that a meritorious exhibit should be marred by a mis-spelt name. "Ah!" says someone, "I hav'n't had much schooling, and my memory isn't good either." Well I do not blame him on these accounts, but what I do blame him for is that he did not obtain and consult a reliable catalogue, and so insure the correct spelling of names. A good catalogue may usually be begged or borrowed, or, if not,

can be bought for a trifle any day; therefore there is no excuse.

Here are a few specimens copied at one of the principal shows in the West of England. I have more, but these are enough to show that there

is room for improvement. "Admiral Warburton" and "Wallburton Admirial" for Walburton Admirable Peach; "Fontail" for Fonthill Plum; "Mcrella" for Morello Cherry; "Adiantium capilis," "Gaacllium,' and "Cresseliam" for gracillimum; "Nephrelepsis" for Nephrolepis; "Elligants" for elegans.

I would ask those whom it may concern if it is not worth while to

give the matter a little more attention? It is not pleasant to stand by and hear young ladies and schoolboys making fun of gardeners' spelling. Nor is there any reason why they should have the opportunity. -WEST ANGLIA.

[A reform in the direction indicated is urgently needed at many if not most exhibitions.]

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 124TH.

SCIENTIFIC COMMITTEE -Present: Dr. Russell (in the chair), Mr. Blandford, Rev. W. Wilks, Prof. Farmer, and Rev. G. Henslow, Hon. Sec.

Galls on Oak.—With reference to the galls exhibited at the last meeting and recognised as those of Cynips calycis, Mr. Blandford observed that they are used for tannic acid on the continent, as well as the more common form, on Quercus infectoria, which contain 50 per cent.

Daffodils and Mice.—Rev. W. Wilks exhibited several bulbs which

had been attacked by Merodon; but subsequently mice had eaten into the bulbs, apparently in order to extract the grub, as no perfect bulb was ever touched. Mr. Wilks intends, and suggests as a means of selection, to spread out bulbs supposed to be affected where mice can have access to them, as the sound bulbs will be left untouched.

Daffodil Decaying .- He also showed a bulb which had decayed up the middle, while the base of the stem was detached together with the

roots. It was referred to Kew for examination.

Onions Diseased.—Some large flattish Onions were exhibited, which had become completely rotten in the middle at the base of the stem. Two-thirds of a crop were said to have been lost. They were also referred to Kew.

Injured Timber, Photograph.—Prof. Farmer showed photographs of sections of an ancient Elm, lately cut down at Oxford. They showed a separation, for three parts of a circle, deeply seated within the stem. As the subsequent annual rings were at first discontinuous over the middle point, but gradually closed over it, the interpretation seemed to be that the tree had been partially decorticated, the wound being subsequently completely concealed.

Proliferous Fern. — Mr. Veitch forwarded a plant of Adiantum (which appeared among A. Capillus-Veneris, but had broader pinnules), having minute fronds starting from the situation of the sori, apparently being aposporous, and developing new fronds in the place of sporangia. Mr. Veitch remarks that this is the first time that he had seen this

occurrence on an Adiantum.

Diseased Pears.—With reference to the Pears sent to the last meeting, Mr. Massee reports that "the fungus is Gloosporium fructigerum, Berk. There is no possibility of arresting the disease in the mature state of the fruit, but this can be done by using the proper remedy during the development of the fruit." The remedy suggested for the same fungus in Peaches was "two or three sprayings of potassic sulphide (one-half ounce to a gallon of water)."

OCTOBER RASPBERRIES AND STRAWBERRIES.

I HAVE picked several small dishes of Raspberries this month, finer and quite as good flavoured as they were in the summer and very highly coloured. I also gathered some on October 27th.—JAS. WICKETTS, Whiteroft, Pershore, Woreestershire.

On the 18th ult. I gathered a good dish of ripc Raspberries, left others some just colouring, but whether they will ripen is a question. The fruit is from the summer fruiting varieties, but the crop was a very light one, the hot dry season having a great effect upon this particular fruit.—G. R. Hemmings, Hollingbourne House, near Maidstone.

MESSRS. S. CHIVERS & SONS, Cambridge, writing under date October 24th to the daily press, say:—"As an illustration of the very exceptional character of the season we have taken the liberty to forward you some fresh gathered Strawberries, being now busy picking and preserving our second crop this year. We have already, during October, gathered 1 ton 5 cwt., and as the plants have still a large quantity of blossom an 1 green fruit we expect to be able to pick double the weight if this mild weather continues.'

REFERRING to Mr. G. Freeman's note (page 355) regarding ripe Strawberries, I may mention during the last week in September and up to the present time I have gathered about four and half dozen of ripe Strawberries from plants grown outdoors. I have only noticed two sorts fruiting—viz., Black Prince and Vicomtesse Héricart de Thury, although one plant of Latest of All bore two or three fruit. Some of the fruit were quite equal in flavour and size to those of the summer. To-day (October 25th) I find there are about one and half dozen of good sized fruits, but many have decayed during the wet weather.—G. WALLIS, The Gardens, Brockley Hall, Brockley.

EVENTS OF THE WEEK.—During the ensuing week many Chrysanthemum Shows will be held, but as a list of those which have been advertised in our columns is given on page 402 further reference is unnecessary. Attention may be called to Messrs. Harrison & Sons' vegetable and root show, which will be held at Leicester on November 8th and 9th. Particulars of this will be found in the advertisement pages.

- THE WEATHER IN LONDON.—A change in the weather has taken place since publishing our last issue. For the first time this season frost was apparent on Monday night, 1° having been registered in Hyde Park. A frost also occurred on Tuesday night, destroying Dahlias in many gardens. The barometer has risen, and at the time of going to press the weather remains cold.
- WEATHER IN THE NORTH.—A great deal of rain has fallen during the month in this district, the really fine days were few. We have now every appearance of an early winter. Snow appeared on the higher hills as early as the 23rd September, and they have since been white to their bases more than once. They are again covered, and frosts of 8° and 9° have been recorded on the last two mornings. Trees have generally lost their foliage, and flowers are virtually over.—B. D., S. Perthshire.
- —— CHRYSANTHEMUMS AND GARDENERS' ORPHANS.—By kind permission of Mr. and Mrs. Hopwood the gardens and hothouses at Ketton Hall Gardens, near Stamford, will be opened to the public on Thursdays, November 9th and 16th, from 2 to 5 P.M. in aid of the Royal Gardeners' Orphan Fund. The fine collection of Chrysanthemums is now in flower, and contains over 1000 large blooms in various stages. Admission 6d. each. Gardener, Mr. W. H. Divers.
- METROPOLITAN PUBLIC GARDENS ASSOCIATION.—We learn that the Prince of Wales has been pleased to signify to the Earl of Meath that it will afford him much pleasure to accord his patronage to the Metropolitan Public Gardens Association, and at the same time to send a contribution of 10 guineas to its funds.
- CORRECTED NOMENCLATURE.—Aglacuema pumilum, not A. "rotundum," is the name of the plant that was figured on page 379 last week, the wrong name having been inadvertently given to the plant when first exhibited. Through a mis-transcription the name of Cirrhopetalum ornatissimum (the proper name) was printed C. "amatissimum" on page 378.
- MAGNUM BONUM POTATO.—Mr. A. Harding, Orton Hall Gardens, Peterborough, writes:—"On October 26th I lifted one of the best crops of Magnum Potatoes I ever saw. The Potatoes were planted the beginning of June, after Ashleafs and Hebrons were earthed up. The tubers are clean, large and fine shaped; being planted late they made no second growth like those planted earlier—a peculiarity of season, I suppose."
- A NEW THAMES EMBANKMENT.—It is reported that a new Thames Embankment is to be formed at Battersea. It is decided now to claim the foreshore by the side of the Thames near Old Battersea Church, and by building a concrete embankment enclose an open space of 2800 square yards. This space when railed in and planted with shrubs and trees will make an open and delightful promenade with a river frontage. The cost is estimated to be £2400, towards which the Metropolitan Public Gardens Association will contribute £1000.
- Wakefield Paxton Society.—At a meeting of this Society last week, Mr. J. Haigh, of Sheffield, read a very interesting paper on "Plants in Dwelling Houses." Nothing, he said, could be more beautiful than floral or foliage embellishments in a house; pictures, statuary, or other ornaments were inanimate, and could not compare with them in effectiveness. It was difficult to choose suitable plants for the varied conditions of heat and cold, light and darkness, dampness and dryness of different rooms in a house, but with care and observation the many difficulties in keeping plants in a state of health and beauty could be overcome.

- —— GARDENING APPOINTMENT.—Mr. Maurice Jones, late gardener to Miss C. Denton, Flemingate House, Beverley, East Yorks, has been appointed gardener to C. C. Arkcoll, Esq., Lime Park, Hurstmonceux, Sussex.
- DAHLIA BRILLIANT.—At the meeting of the Floral Committee of the National Chrysanthemum Society held on the 25th ult., a first-class certificate was awarded to Messrs. H. Cannell & Sons for Dahlia Brilliant, a rich deep crimson flower of the true Cactus type.
- PRESTON AND FULWOOD HORTICULTURAL SOCIETY. Mr. Charles Parker, 11, Cannon Street, Preston, has been appointed Secretary of the above Society in place of Mr. John Atherton, who resigned. The spring show of the Society is fixed for March 14th and 15th, 1894.
- THE DEVON AND EXETER GARDENERS' MUTUAL IMPROVE-MENT ASSOCIATION.—At the meeting of the above Association, held on the 25th ult., in the Guildhall, Exeter, Mr. Andrew Hope, of Messrs. R. Veitch & Son, read an able and interesting paper on "Plant Names and Their Association." The chair was occupied by Mr. G. B. Langsdale, and there was a large attendance of members.
- Mr. C. Orchard, we learn, has given up the management of the Bembridge Hotel, I.W., and taken over the Gardens on the reclaimed land from the Brading Harbour Co., with a view of developing a florist's business, as well as supplying the hotels belonging to the Company with cut flowers, vegetables, and other produce. Mr. Orchard's present address is 2, Harbour Mount, Bembridge, Isle of Wight.
- Gustavia Pterocarpa.—In a recent issue of the "Garden and Forest," Mr. G. Nicholson remarks that this plant has been flowering in the Palm house at Kew; all the species of the genus are handsome plants, well worth growing. The present species has large flowers—about 4 inches or more across—somewhat like those of a Magnolia in shape; the petals are white inside and rose-tinted externally. The inflorescence consists of about ten flowers; the stalked, leathery leaves measure from 12 to 20 inches in length and from 4 to 6 inches in width.
- LARGE VEGETABLES.—We learn from a Cumberland contemporary that there was a unique collection of fine vegetables filling the front windows of Messrs. Little & Ballantyne's establishment on Saturday last. The specimens were all sent to the firm from growers in the neighbourhood of Carlislc. There were white Cabbages 20 lbs. weight, Red Cabbages 16 or 17 lbs.; Brussels Sprouts nearly 3 feet high, "buttoned" to the very top; pink and white Celery, which had displaced a depth of $2\frac{1}{2}$ feet of soil; Leeks, of the Musselburgh variety, 8 or 9 inches in circumference; large round Onions from 1 lb. to $1\frac{1}{2}$ lb. in weight; Marrows of extraordinary dimensions, and a Gourd weighing 30 lbs.
- —— Pot Marigolds.—These plants are the hardiest of annuals and give a fine show of flowers during the summer. If sown, however, in May a display of bloom is seen all the autumn, and that is very important. Amongst the very latest to flower outdoors is Orangc King, one of the most effective of all, because the rich hue is particularly striking at this dull season. The old form of pot Marigold, a poor and uncertain flower, is quite elbowed out by such beautiful varieties as those named; Prince of Orange partially flaked with white; Meteor, the petals striped white and yellow. Some varieties are self, lemon, or occasionally tinted with a dark hue on the tops of the petals. All these are excellent in gardens, all are beautiful, bloom freely, and endure longer than other hardy annuals.—A.
- COLOURING FRUIT. Have you ever noticed what a fine colour most of the fruit offered for sale in the street generally possesses? It is all a question of dyes, remarks a "Society" journal. Ordinary Oranges are dyed a deep red, which enables them to be passed off as fine Blood Oranges at an enhanced price, especially when they have been made half as large again by boiling. Pine Apples are also tinted to make them look more attractive, and hard, unripe Strawberries are dyed so as to look a deep, luscious red. Melons are coloured a deep orange, and essence of Melon is injected to increase their flavour The latest development of the business of colouring fruit in France is in connection with Pears, which are dyed blue for a third of their size and red below, so that they present the national tricolour when peeled They are said to be in great demand for dessert fruit on account of their novelty, just as the green Carnations were over here with certain persons.

THE ROYAL GARDENERS' ORPHAN FUND.—What was most fitly termed a grand concert was given at the Surbiton Assembly Rooms on Wednesday evening of last week. The programme furnished by Mr. W. Furze of Teddington, was a first-class one, the company large and fashionable, and the entire programme, every item of which was capitally rendered, gave the highest satisfaction. We learn that H.R.H. the Duchess of Albany kindly sent a donation of 20s. to the Concert Fund through Mr. A. Dean, the Secretary. Also through him Messrs. J. Laing & Sons, the well-known Begonia growers of Forest Hill, sent a very handsome bouquet for presentation to the Mayoress of Kingston, in recognition of the Mayor and Mayoress's patronage. The Committee met on Saturday evening last to balance accounts, everything being conducted with great economy, Mr. Furze and Mr. Dean even finding all refreshments for the artistes. The result is a balance of 21 guineas, which will be duly forwarded to Mr. A. F. Barron.

— ÆCHMEA MARIÆ REGINÆ.—A writer in the "American Florist" thinks that this plant is the handsomest Bromeliad ever introduced. It is strong in habit, having large leaves 12 to 18 inches in length, armed at the edges with sharp spines. The flower scape is erect and covered about half its length with large boat-shaped bracts of a rich magenta shaded with rose, which remains a long time in perfection; the upper portion is thickly covered with flowers, which are tipped dark blue, changing with age to rose. It blooms during June and July. It is one of the most gorgeous and striking plants in cultivation, and never fails to attract attention.

- CARYOPTERIS MASTACANTHUS.—Regarding this plant a writer in the "Garden and Forest" says: "Although long since it was first introduced into cultivation this is rarely found in gardens. It is a smooth, branchy little shrub, having much the habit of a Ceanothus or Callicarpa, to which latter family it is allied. C. Mastacanthus does not appear to be truly hardy in some parts of America, although it has not been fairly tested out of doors with a proper winter covering. But it blossoms so late and so profusely, and is altogether so attractive, that it is well worth the trouble to lift it in autumn and place it in a pit or cold frame and to replant it again in the spring. There are dry, sunny, sheltered spots even about Boston where it might possibly live and thrive without removal in winter. The flowers, which are individually small, are borne in close corymb or umbel-like clusters in the axils of the opposite leaves and on all the branches. Blossoming begins in September, and as the twigs continue to grow new flower buds are produced with each new pair of leaves until further growth is checked by cold weather and frosts. The blooms are of a rich violet or lavenderblue colour, and have a slight aromatic fragrance. The foliage, green above, is soft, downy and hoary white beneath, and when bruised it gives out a very powerful, pungent, aromatic odour strongly suggestive of some plants of the Mint family, although this plant is generally classed in the Verbena family. It may be readily propagated by cuttings."

- SURREY APPLES. - Talking the other day about Apples and Pears at Cranleigh, I was greatly pleased to find a couple of local growers (Mr. Knight, an old Chiswick man, and gardener to Mr. Cassilla, Cranleigh; and Mr. Donkin, who has embarked in fruit culture in a small way for market) could bring and exhibit such excellent samples of fruit, especially the former. His Apples were gathered from young standard trees in an orchard, and were most clean and handsome. His Quinces were some of the finest fruits I ever saw. Blenheim Pippins large and richly coloured; Hereford Queening, a fine late variety; King of the Pippins and Wyken Pippin, all perfect samples. Mr. Knight stated that on the sand in that district Blenheim trees began to fruit much earlier than is the case on stiff soils. The exhibit showed what could be done with hardy fruit in that part of the county of Surrcy, and indeed it is a grand fruit-growing district, with few exceptions unhappily devoid of fruit. When it is known that for its area, its superb aspects, varied soils, and many suitable surroundings Surrey is credited in the returns of the Board of Agriculture with having only 3000 acres under market fruit culture, such evidence as was afforded at Cranleigh of the capacity of the district to produce fine hardy fruits should have good effect. Mr. Knight had exhibited his samples at the local agricultural show there the previous day, and it is hoped that all classes, especially landowners and farmers, took note of them. It is so very obvious that what can be done by Mr. Casilla, who has planted largely, could be done by many others, and it is hoped that very soon the reproach to Surrey of being such a poor fruit-growing county may be removed.—A. D.

— BIRMINGHAM AMATEUR GARDENERS' ASSOCIATION. — Mr. Arthur Roe read an interesting and instructive paper on "Our Herbaceous Border" before the members of the Amateur Gardeners' Association, at the Temperance Institute, last week. He contended that herbaceous plants were rightly taking a foremost place among the popular plants of the day. Beds of Pelargoniums, Lobelia, Asters, and Stocks produced an admirable display of colour, but there was always a certain sameness about such plants. A well-selected collection of herbaceous plants could be grown easily in a town garden, and would provide us with flowers from the early dawn of spring till the closing days of autumn. Amateurs, he said, had overlooked the beauty and variety of these plants in the past, and had neglected their cultivation.

WINTER RADISHES.—I have a vivid recollection of the ancient black Spanish Radish, at one time commonly grown in gardens for winter salading. It was sometimes round and oval and long, but always had a nearly rough black coat, the flesh white, rather hard and exceedingly hot. We have better winter Radishes now, and very mild pleasant ones too in flavour, like the fleshy young fresh Turnip Radishes. I saw a couple of these winter varieties in the seed farm at Reading the other day, one a long white, large, but very soft pleasant flesh, exceedingly agreeable, from Japan, and a pretty long tapering-rooted variety called Chinese Rose. These Radishes if pulled just when at their best and preserved as other tap roots are for the winter, then when used are washed, peeled and sliced, are most valuable additions to mixed salads during the winter.—A.

THE GREAT YORKSHIRE GALA, YORK. — The balance-sheet for the current year has just been issued, and is a most satisfactory statement, with a reserve fund of £2000, and other assets amounting to £256. During this year £250 was given to the York charities, £614 12s. in prizes and judges' fees, £115 12s. for music, £340 for tents and other fittings, and over £300 in other amusements incidental to the annual Gala. The receipts at the gates on the three days amounted to £1850, and from other sources to £524 10s. Whilst offering our congratulations to the energetic Committee and Secretary, we venture to suggest that in the coming year the claims of the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund may have favourable consideration, for both urgently need help, and horticultural societies may do so much—if they will—in helping both institutions.

- NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).—The annual general meeting of the above Society was held at the Hotel Windsor, in the rooms of the Horticultural Club, by kind permission of the members, on Saturday, October 28th. Martin R. Smith, Esq., President of the Society, presided over the meeting. The President, Vice-Presidents, Committee, and office bearers were re-elected. It was decided to hold the Exhibition for 1894 under the auspices of the Royal Horticultural Society on July 24th. The following alterations were made in the schedule :- Two new classes were added of twelve blooms and six blooms respectively, with a growth of the plant to each bloom, and without dressing. It was also proposed and unanimously adopted that the class for yellow ground Picotees be judged on the same principle as the white ground varieties—that is, a pure yellow with a margin the same as the white ground class; fancies not to be admitted. A distribution of seed has been made to the members, saved from choice fertilised flowers, grown in the garden, of the best seedlings raised from the seed so distributed on a previous occasion. The statement by the Treasurer showed that the Society was very prosperous as regards finance. The subscriptions, as per list, amounted to £154 9s. 6d.; amount for special prizes, £18 17s. 6d.; prize money distributed, £99 15s. 6d. The balance from last year was £65 10s. 5d., and the balance in hand is £118 5s. 4d.—J. Douglas, Hon. Sec.

THE ANNUAL MEETING OF THE AURICULA AND PRIMULA SOCIETY was held at the same time and place. Mr. Henry Cannell of Swanley presided. The President, Vice-Presidents, Committee, and office bearers were re-elected, the name of Mr. J. T. Bennett-Poë being added to list of Vice-Presidents. The Exhibition for 1894 is to be held under the auspices of the Royal Horticultural Society as usual, and it was decided to offer the same prizes as last year. The subscriptions as per list amounted to £63, prizes paid £60 16s., other expenses brought the expenditure up to £74 1s. 6d., leaving a deficit on this and last year's working of £8 16s. 6d. due to the Treasurer. If all the members would pay up their subscriptions, this amount would be materially reduced, and with a very little effort on the part of the members the deficiency might be made a handsome surplus.

- THE WEATHER IN WEST YORKSHIRE.-Round this district (Bingley) the weather during October up to the 25th has been exceptionally mild. Since then we have had cold north-west winds, accompanied on the 26th and 28th by heavy showers of rain. This morning, the 30th ult., we registered 7° of frost, which has put an end to the Dahlias and other flowers.—T. H. BOLTON.

- AMARYLLIS BELLADONNA.—Mr. Divers (page 375) is correct in stating that the warm wall of a heated house has a beneficial effect on the bulbs of this plant. I have had ample proof that they are assisted by the extra heat to a very great extent. Some years since I frequently visited a garden in which was a range of glass divided into two houses—a stove and a greenhouse. Between the front wall and the path outside was a narrow bed of Belladonna Lilies the whole length of the range. When the plants were growing the difference in their appearance was remarkable, and even more so when in flower. Those near the wall of the stove grew taller, and produced a much larger number of finer scapes than did the remaining portion of the bed by the cooler wall of the greenhouse, this being the case year after year. Had the bulbs been lifted no doubt as great a difference in their sizes would have been apparent.—T. S., Bristol.

- EARWIGS. - During the summer and autumn the earwig was particularly abundant - i.e., the familiar Forficula auriculare, the smaller dermopterous species of the genus Lebia, did not appear to be more numerous than usual. It would be of interest if gardeners who had observed any facts concerning this insect in the past season would kindly report them. For instance, it would be very desirable to know what plants or shrubs it chiefly infested. Here, in Gravesend, I have been told the species was caught repeatedly in the act of biting the young shoots of Chrysanthemums. Also it is important to have further evidence as to its flying, and whether it uses the forceps at the tail to inflict a pinch should it be assailed. some doubt amongst entomologists as to its habits, and its early history is still very obscure. I imagine the eggs are laid in or on the ground during the autumn, and the young brood lead a subterranean life, or almost so. Many of the mature earwigs seem to survive till the next spring, however, hiding in nooks and under bark.—J. R. S. CLIFFORD.

CHRYSANTHEMUM SHOWS.

WE have received numerous intimations of Chrysanthemum shows which are to be held during the current month, but space can only be found for the enumeration of those that have been advertised in our columns up to date, of which the following is a list:-

- Nov. 3rd and 4th.—Crystal Palace. ,, 7th and 8th.—National Chrysanthemum Society (Royal Aquarium), Kingston, Liverpool, Leeds Paxton, Brighton, Watford. 8th and 9th.—Northampton, Bournemouth.
 - 9th.—Birkenhead and Wirral,

 - " 10th and 11th.—Bradford, " 14th and 15th.—Twickenham, West of England (Plymouth). " 15th and 16th.—Birmingham, Hull, Bristol, South Shields, Rugby. " 15th, 16th, and 17th.—Herefordshire. " 16th, 17th, and 18th.—Edinburgh, York.

 - "17th and 18th.—Bolton.
 - ,, 24th and 25th.—Eccles and Patricroft,

SHOUTING OF THE SHOWMEN.

IF the National Chrysanthemum Show must be held at the Aquarium could not a two-shilling door be arranged for the admission of ladies and others before pipes are lighted and the shouting of the showmen begin?—SMALL GARDEN OWNER.

CHRYSANTHEMUMS AT CALDERSTONE—A CORRECTION.

In my report on Chrysanthemums at Calderstone in last week's issue (page 382), I stated that Lucy Kendall was a good yellow sport from Mrs. Heale, but that Mr. Tunnington feared confusion with it and Miss Haggas. For Lucy Kendall it should read Richard Parker .-R. P. R.

OUT OF DATE CHRYSANTHEMUMS.

It has often occurred to many that it would be a good plan to publish a list of the Japanese varieties which are superseded. As a trade grower I am frequently asked to send the "very best, regardless f cost," and only this spring such varieties as the following were asked

for, all of which, as exhibition flowers, I have discarded from my collection:—Madame C. Audiguier, Peter the Great, Meg Merrilies, and others. Of those of more recent introduction I have discarded as being superseded are Mr. Beckett, Mrs. Beckett, Sarah Owen, Jeanne Delaux, Mons. Freeman, W. W. Cole, Coronet, Pelican, Louis Boehmer, Alberic Lunden, Mr. H. Cannell, and Mrs. C. W. Clark.—PROGRESS.

THE WHITE VIVIAND MOREL.

Would some correspondent of the Journal of Horticulture kindly inform me if Viviand Morel, the true variety, and Viviand Morel on an early bud, coming pure white, and named Mr. W. Wells, would be disqualified under the rules of the National Chrysanthemum Society if they were both shown in one stand of twelve distinct Japanese varieties? As a beginner, I fail to see how a judge could disqualify them if one was a true pink, the other a pure white, although I do not think the latter has been certificated.—A Young Beginner.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday last at Anderton's Hotel, Fleet Street, when Mr. R. Ballantyne occupied the chair. Most of the business was of a purely formal or routine nature consequent upon the approaching exhibition. The Secretary stated that prize money amounting to £37 10s. had been awarded at the Society's Show last month independent of the cost of medals and special prizes, £6 11s. for vegetables, which amount was given by Messrs. Sutton & Sons of Reading. The Committee then confirmed the award of medals made by the Arbitration Committee at the October Show. The financial statement up to date being submitted showed that the sum of £235 11s. 4d. had already been received by the Secretary, of which amount £113 19s. 6d. was for subscriptions and £36 14s. 6d. for fecs-from affiliated Societics. The annual dinner, at which the President, Sir Edwin Saunders, is expected to preside, will take place at Anderton's Hotel on Thursday the 30th November. The Sub-Committee for the 1894 schedule was then appointed, its members consisting of Messrs. G. S. Addison, Boyce, Davey, G. Gordon, G. Stevens, Bevan, Crane, C. Gibson, H. J. Jones, B. Wynne, and W. H. Fowler, with the officers as ex-officion members. New members numbering altogether twenty-eight. were elected, and the Beckenham Horticultural Society admitted in affiliation.

Mr. D. B. Crane called attention to the inconvenience experienced after the last Floral Committee meeting, when exhibits were cleared away almost immediately after the sitting was over, giving members no opportunity of seeing the awards made. It was explained that this was a contravention of the rules on the part of exhibitors, and that in future the exhibits would remain on view until 4 P.M. as usual.

A vote of thanks to the Chairman brought the meeting to a close at an early hour.

NEW CHRYSANTHEMUMS.

AT the meeting of the Floral Committee, held at the Royal Aquarium on the 25th ult., there was an excellent display of novelties, the principal of which were Mr. Charles Cox, a crimson sport from M. Bernard, which the Committee desired to see again; Duchess of Devonshire, a Japanese medium-sized flat flower of deep rosy colour with golden reverse; Belle Jaune, a very attractive deep yellow Japanese, which was commended; Richard Dean, a large crimson Japanese with golden reverse; W. H. Fowler, a finely formed Japanese with deep spreading florets, colour bright yellow; Miss M. Simpkins, a large globular incurving Japanese with sharp-pointed florets, colour creamy white. In Anemones, Ada Strickland, a self-coloured bloom of deep cinnamon yellow, was effective, but the disk was not fully up. Madame M. Ricaud, a deep rosy blush-coloured Japanese with golden centre, was commended. G. W. Childs, a Japanese of rich velvety bright crimson, was staged in good condition, as also was Snow, a large white Japanese with long petals which the Committee wished to see

First-class certificates were granted to-

Thus. Witkins (Mr. R. Owen) .- A bright chrome yellow Japanese;

petals flat and spreading.

Mrs. P. Blair (Mr. R. Owen).—A large bloom of the incurved Japanese type, pale purple with silvery reverse.

Violetta (Mr. E. Beckett).—A deeply built flower, colour soft rosy

violet; an excellent Japanese seedling, raised in England.

Malle. Nathalie Brun (Mr. Rowbottom).—A large Anemone variety, centre pale yellow and high up, ray florets white and quilly.

Tribune (Mr. H. J. Jones).—A first-class Japanese of pale yellow lemon, rather deper towards the centre; a bold globular bloom; This

variety is figured on page 403.

Yellow Lady Selborne (Messrs. Rochford & Son).—A yellow sport from a well-known useful old favourite.

Madame Cambon (Mr. C. Gibson).—An unusually massive incurved Japanese; colour pale straw, petals long, curly, and intermingling.

How to Prevent Damping in Chrysanthemum Flowers.

FEW things are more calculated to suppress the enthusiasm which Chrysanthemum growers usually exhibit at the present time of the year than to notice their finest and choicest blooms being gradually ruined through damp before their beauty has fully developed. Yet this, alas! is the annual experience of many throughout the country. Even this year, though the weather has apparently been favourable for ensuring rapid and perfect development of the flowers, we hear many complaints of heavy losses through damp. Few growers perhaps altogether escape its damaging effect upon some of their flowers, but wholesale damping, such as we sometimes hear of, may, in my opinion, he prevented if sound judgment as well as assiduous attention are bestowed upon the management of both the plants and the houses in

interests of all to be thoroughly thrashed; out, seeing how many grand blooms are each year lost through the inroads of this dread enemy Observation has taught me that there are three distinct kinds of

Observation has taught me that there are three distinct kinds of damping; the most common form is for the lower florets of the flowers to become discoloured at the points, and if not removed premptly to decay the entire length, and prohably convey the germs of decay to the

FIG. 59.—CHRYSANTHEMUM THE TRIBUNE. (See page 406.)

which they are arranged. Although I have no wish to pose as an egotist I feel some satisfaction in the fact that during the ten years in which I have grown Chrysanthemums on the "large bloom" principle very few losses have been experienced through damping. If the causes and prevention of it, which I am about to advance, do not agree with the teachings of the giants in Chrysanthemum culture, they will be doing both me and many other readers of the Journal good service by setting us right in the matter, for I consider it a subject which lought in [the

centre of the flower. This is frequently brought about by great fluctuations in the condition and the soil in regard to moisture. Plants which do not retain their foliage well till the opening of the flowers is well advanced are invariably extremely sluggish in their root action; under such circumstances, if water is given before the soil is dry enough to admit of the pots ringing sharply when rapped, damping inevitably follows sooner or later. It may be noticed the following day if damp or foggy weather prevails. Sometimes strong healthy plants carrying

the finest buds are incautiously given an overdose of stimulants, which causes many of the surface roots to be destroyed, and a corresponding loss of foliage. The florets then for a time expand so slowly that with the best of attention it is seldom possible for the flower to become fully developed before the lower petals begin to decay through age, consequent upon impeded root action having prevented the flower from opening in its usual time. In such instances it is a good plan to remove as much of the centre of the flower as is thought will not expand while the lower petals keep fresh; although this kind of damping is usually caused through over-watering, combined with a damp and stagnant atmosphere, it is sometimes brought about by the opposite extreme. Knowing the evils which arise from over-watering, some cultivators nervously avoid the medium course, and allow the plants to become too dry at the roots, especially during bright weather. When in this condition, if the flowers are examined before water is given, the florets will be found to have temporarily lost their crispness, and feel soft and flabby to the touch. The application of water renders the stem crisp and firm again, but the following day a slight discolouration of the lower florets may be noticed, the whites and yellows frequently become tinted with pale pink, which most of us know is a sure indication that their freshness is on the wane.

Perhaps the most destructive form of damping is that which shows itself in spots or blotches over the whole or only certain parts of a flower. Almost every flower in a house is sometimes more or less affected in this way. This wholesale damping, which is indeed calamitous, may, I believe, be almost entirely prevented if no mistakes are made in the management of ventilation and artificial heat, and a little chade is indiciously given. The condensation of maintane upon the shade is judiciously given. The condensation of moisture upon the flowers is the cause of this damping. If the moisture is allowed to remain upon them for any length of time they become much discoloured. On the other hand, should evaporation take place very quickly many of the flore's shrivel as if they had been sealded, and indeed the disaster is brought about in much the same way as that which induces scalding Our remedy, therefore, is to prevent the condensation of moisture upon the flowers. This may undoubtedly be accomplished by keeping a little heat in the hot-water pipes whenever the weather is dull or damp, and at all times leaving the top ventilators slightly open wherever they are so arranged as to prevent rain entering the house. So long as the heat remains in the pipes I have never found any harmful effects from leaving air on at all times, and it proves as if even the safety valve through which superfluous moisture is dispelled. If on entering the house early in the morning moisture is seen hanging in drops upon the glass and sashbars, it may be taken for granted that the heat has not been kept regular. Should the hot-water pipes be found quite cold the first thing in the morning it is a mistake to push the fire on sharply and get them very hot. This should be done gradually, otherwise a great amount of drip will take place.

Those who have houses with iron sashbars will find the greatest difficulty in preventing the condensation of moisture on the roof, and consequent drip, but with continual ventilation and steady heat it may in all instances be reduced to a minimum if the more air is admitted in the morning before the temperature begins to rise. This is important, as I find many are inclined to delay the admission of more air till too late. Whenever the day promises to be bright it is advisable to have the pipes cool by the time the sun strikes the house, otherwise the rapid evaporation caused by the action of sun, air, and fire heat combined will assuredly cause the florets to scald, and although shading plays an important part in preventing this it will not do so entirely. There is one other form of damping which is happily not very frequent. Sometimes a flower may open in a satisfactory way up to a certain stage, when it ceases to make further progress, but to all appearance is quite sound; closer inspection will, however, reveal the fact the centre at the base of each floret is quite decayed, and the flower useless. Drip falling into the centre of the flower would, I have no doubt, produce a similar effect, but I think it is seldom caused in that way, because I have never noticed this happen in the case of a plant which was quite healthy and vigorous up to the time of the occurrence. Its advent is usually marked by the soil not drying so quickly as formerly. This I think is eaused by overfeeding to the extent of bringing about a complete breakdown in the constitution of the plant, or by persistent over-watering, which in time kills many of the young roots.

At all times the plants should be arranged as thinly as the space at command will allow. Packing them closely together, so that after watering the soil is so long in getting dry again renders the work of preventing damping all the more difficult. I am firmly convinced that if many cultivators would grow fewer plants, and thus avoid crowding when the time arrives for housing, they would produce a proportionately greater number of really good flowers.—D. H.

CHRYSANTHEMUM PROSPECTS AROUND BOLTON.

ONCE again has the season come round to record the prospects of the Chrysanthemums, and from a visit that has been made to the many excellent collections grown in the neighbourhood of Bolton, it is gratifying to note that there is no abatement in the enthusiasm in the cultivation of the "Autumn Queen." The plants are the finest ever grown in the locality, showing that whatever may have been the effect of the excessively hot summer in other parts, it has been conducive to the well-being of Chrysanthemums in this rather uncongenial climate.

It is not my intention to enumerate what I found in each collection separately, further than saying on all sides, both where they are grown for home decoration as well as where cultivated for exhibition,

very fine displays are anticipated. Foremost amongst the Japanese are Viviand Morel, Mdlle. Marie Hoste, W. H. Lincoln, Mrs. F. Jameson, W. Tricker, Florence Davis, Stanstead White, W. W. Coles, Puritan, Gloire du Rocher, Edward Molyneux, Avalanche, and J. Stanborough Dibben. Of the new kinds the most promising are William Seward, John Shrimpton, Lord Brooke, Col. W. B. Smith, G. W. Childs, and Mrs. E. D. Adams.

Amongst the incurved those of the Queen family are remarkably fine, so also are the Princess of Wales and all its sports. The same applies to John Salter, Lord Wolseley, and Jeanne d'Arc. Of the new kinds Mrs. Robinson King, Madame Darrier, Mrs. Clibran, Ami Hoste are the most promising, and Mons. R. Bahuant is grand.

In many cases I fear the bloom will be too early for our forthcoming

Show, November 17th and 18th, for which a very comprehensive schedule has been prepared and liberal prizes are offered. The great event to Bolton people is the President's (R. K. Cross, Esq.) prize, a handsome silver cup for twelve incurved and twelve Japanese cut blooms. This class is confined to growers residing within eight miles of Bolton. leading class in the open section is for twelve incurved and twelve Japanese cut blooms, and the prizes are £5, £3, £2. For a similar class of twenty-four cut blooms, miscellaneous, the prizes are £3, £2, £1. We hope the Show this year will be the best we have ever had, for in addition to our ordinary prizes we are giving two medals of the Royal Horticultural Society, and every endeavour is being made to make it a success by the Committee and its Secretary, Mr. Hicks, Markland Hill, Bolton. VISITOR.

CHRYSANTHEMUMS IN THE SOUTH.

Now that the exhibition season is close at hand a few notes on the prospects of the leading growers and exhibitors from any neighbourhood are interesting, and being lately in the Portsmouth district I had a glance over a few collections of plants.

ROOKSBURY PARK.

This, the seat of J. Carpenter Garnier, Esq., produced the winning blooms at the exhibition held at Portsmouth last year. Mr. N. Molyneux has some promising plants, not too robust in growth, but with wood fully matured and likely to give blooms of high quality, it not of exceptional size. The Japanese varieties are more advanced than their compeersthe incurved—and include all the novelties of last year as well as some promising kinds for this season. Such varieties as G. Savage, Princess May, L'Ami Eticnne, G. C. Schwabe, Mrs. C. H. Payne, W. K. Woodcock, Princess Victoria, John Shrimpton, W. Seward, President Borel, Le Verseau, Lord Brooke, Le Prince du Bois and Charles Davis are worthily represented. The incurved section are later. All the time available will be needed to develop the blooms fully by the early shows. The second week in November should see here a fine display.

LEIGH PARK.

This, the country residence of Sir F. Fitzwygram, is a few miles from Portsmouth and close to Havant, another centre of Chrysanthemum interest. Mr. Penford has for some years past been a leading exhibitor at the shows in the district, as well as at Brighton and Southampton. He has excellent plants this year—in number about 500. The Japanese section promised to afford some grand blooms. Florence Davis was remarkably fine; the same remark applies to Edwin Molyneux which was especially rich in colour, Excelsior, Anna Hartshorn, Marquise de Paris, Mrs. C. H. Payne of huge size, Stanstead White, Beauty of Castle Hill, W. Seward, and Sunflower. The leading kinds in the incurved section were naturally later but most promising in appearance. Nowhere in the south have I seen the Anemone sections better shown than from here. This year bids fair to be no exception to the rule from the present appearance of the plants.

HAVANT.

Mr. Agate's Chrysanthemum nursery is well known, not only for the quality of the blooms produced, but for the number of new sorts yearly on trial. Prominent amongst these carrying good blooms were Charles Davis, the new sport from that now universal favourite Viviand Morel, Madame Octavie Mirbeau, Duke of York, Golden Wedding, Miss Watson, Lord Brooke, G. Savage, The Tribune, W. H. Atkinson, G. W. Childs, Robert Owen, Mrs. Hubbuck, and Beauty of Exmouth. The incurved section were later, but promised well. Several new sorts are on trial, of which more may be heard later.

STANSTEAD PARK.

Mr. Hoskins, the gardener here, although not an exhibitor, grows not less than 700 plants, producing blooms of show quality. The Queen family are very late, many of them being run on to terminal buds. Prince Alfred, Jeanne d'Arc, Nil Desperandum, Refulgens, and Novelty are very good. Bouquet des Dames is here a great favourite in the Japanese section, and so are Avalanche, Sunflower, Viviand Morel, and Edwin Molyneux. It seems a pity that with such fine plants Mr. Hoskins does not exhibit the produce at some of the neighbouring

SWANMORE PARK.

Although not at the present time an exhibitor, Mr. Molyneux cultivates quite as many plants as when he tried to win prizes. The majority of the new sorts are grown with a view of testing their capabilities. Owing to structural alterations the plants are later than usual, but judging from the moderately strong yet firm wood and stout leaves good blooms may be expected later on. Amongst the newer varieties the following were promising, beside a number of seedlings under trial:—C. Davis, C. Blick, W. Seward, Princess May, Comte de Paris, G. W. Childs, Excelsior, L'Enfant des Deux Mondes, Mrs. C. H. Payne, Le Verseau, Madame Octavie Mirbeau, Mrs. W. H. Fowler, and Potter Palmer. All the old and tried favourites are here grown, as well as the best of the incurved varicties. Several plants of all sections are grown without any disbudding or thinning of the shoots after being once topped when a few inches high. This is for testing their floriferousness, and an interesting display may be expected from these plants.—VISITOR.

CORNSTILES.

This is the residence of W. F. Flight, Esq., who is well known as a patron of the Chrysanthemum. His gardener, Mr. Neville, has a collection of dwarf well ripened plants that should produce fine exhibition blooms. Most noticeable amongst the incurved are the Princess family, which are well timed. The Japanese varieties are grand, comprising many new novelties. I noticed that J. Shrimpton and Beauté de Toulousaine were specially good. Mr. Neville, I think, will take some beating this year.

MESSRS. W. & G. DROVER, FAREHAM.

The blooms staged at the Centenary Exhibition by these growers brought their name to the front. They are now growing about 400 plants for producing exhibition blooms. These are arranged in two long lean-to houses, one for Japanese, one for incurved varieties. The plants are taller this season, but are fine in stems, and the foliage is stout and green. The wood is also well ripened. I noticed Baron Hirsch, Brockley Gem, and the Queen family are showing good colour and depth. The varieties of the Princess family will not be up to their usual form this year. The Japanese are most promising, especially W. Seward, Colonel W. B. Smith, Lord Brooke, G. C. Schwabe, Golden Wedding, Charles Davis, Mrs. C. H. Payne, Mrs. Alpheus Hardy, and a few good promising seedlings.

THE VICTORIA PARK, PORTSMOUTH.

The plants grown by Mr. Hatch for exhibition blooms number about 250, and about 150 plants are cultivated for groups. These are showing well. Pompons and singles are also well grown. Mr. Hatch has taken many prizes for cut blooms, also for groups.—A GARDENER.

CHRYSANTHEMUMS IN THE ISLE OF WIGHT-NEW VARIETIES.

In spite of the extra amount of heat and sunshine during the past summer, Chrysanthemums in the south are a little late on the whole. Nevertheless, by the time the exhibitions come on I shall indeed be surprised if the season does not prove to be one of the best of the past decade as regards the improvement in the varieties of the Japanese section. New life has been irstilled into the cultivation of the flower by the interest taken in the hybridising and raising of English seedlings, the character of which can be fairly well proven the first season.

There is no doubt but that the fine hit made by Mr. J. Shrimpton, gardener to W. Seward, Esq., by the raising of the brilliant varieties named after the raisers and introduced last season will be in evidence this year at most of the exhibitions, and there are others to follow that will leave their mark. How the name of Shrimpton revives old memories of the past, in the minds of some of the old Stoke Newington school, and others of more recent date, when the Kingston and Wimbledon gardeners used to flock in scores across Wimbledon Common to visit our old friend of that name that lived at Roehampton, and grew such flowers as no one else could at that time, twenty to twenty-five The sight of his flowers gave the fever to many young gardeners that have since made their mark in the Chrysanthemum world, and by the zeal displayed in the neighbourhood resulted in the establishment of the Kingston and other neighbouring Chrysanthemum Societies. In the history of the Chrysanthemum I am glad to lay my tribute to our late friend, and many of my Kingston and Wimbledon associates can, I am sure, bear testimony to the wonderful influence "Shrimpton's" Chrysanthemums had on the gardeners and others at that time. This season will prove that history repeats itself, although the bearer of the honoured name, the raiser of the new varieties under notice, told the writer of this personally last season he could not elaim any relationship to our old friend of Roehampton.

The above thoughts suggested themselves on a visit to the unique gardens at Yarborough House, Brading, the residence of J. Darley, Esq, whose gardener, Mr. George Burt, has "taken on" wonderfully, and grows the Chrysanthemums, as he does anything else he takes in hand, with very great success. Favoured by a delightful sheltered situation, and a maximum amount of sunlight, the colours are highly developed, the collection consisting of nearly all new varieties. Last season Mr. Burt crossed a late bloom of Mrs. E. Beckett with J. Stanborough Dibben, and have now about thirty plants showing colour in different stages and of different characters, one of which, not yet named, is a beautiful distinct reflexed Japanese about 2 feet 6 inches high, carrying three fine flowers about 6 inches across, of a deep primrose, with shades of bronze and red in the centre of the flower; a variety of great promise. The following are some of the best, all of which are good, produced on plants carrying clean fully developed flowers fit for any exhibition. The high coloured varieties are very telling. Wm. Šeward, deep crimson, with long florets, is prominent on the three or four plants; all are fine, one carrying eleven flowers of good substance; like all dark coloured varieties, they require to be shaded from the hot sun to prevent burning. J. Shrimpton is a grand crimson with a golden turnover on the tips of the reflexed florets; both these varieties show unmistakeably the blood of Cullingfordi in the wood and foliage. C. Shrimpton is another high coloured variety, but the flowers are not so promising as the preceding, having come single on the terminals. Alice Seward is a very pretty variety with incurved florets, purple rose splashed with white, with a silvery turnover, reminding one of Don Quixote, but very much better. Charles Davis, the bronze yellow Viviand Morel, is represented by three plants, each carrying finely developed blooms of a beautiful tint, reminding one of Criterion, but much larger. L'isere is a splendid variety with large spreading stout florets, white, with a cream shade, turning up at the points like Stanstead White or Mdlle. B. Pigny, of which it is a much improved variety, both in the flower and the habit of the plant. I predict a good run on this variety.

Louise is a very fine incurved Japanese of extraordinary substance, like a huge Queen of England, a soft peach colour. Lord Brooke is a grand acquisition in colour; the flower here is of great substance, and the plant very showy. White Louis Boehmer, a small plant carrying three fine blooms, pure white, and very hairy; better than Mrs. Alpheus Hardy. Madame Appin, light rose, reminding one of a pale Viviand Morel; a fine exhibition flower. Col. W. B. Smith on all plants is very good, one plant carrying fourteen blooms; this is a great acquisition. Hubbuck, deep purple amaranth, very full flower with drooping florets. Excelsior, showing a good colour, deep rose, with silvery turnover. Waban, large, not yet fully developed. Chas. Blick, deep yellow, is very good. Elma de Smith, deep chestnut red, is very promising. Miss Dorothy Shea, large flower, with drooping florets of a dull brick red, reminds one of Margaret Marrouch, but as coming here, not quite so full; when good it would cover the board. Princess May has long drooping white narrow florets, and Le Prince du Bois is a very pretty flower, soft yellow drooping florets like Sunflower. Mrs. C. Harman Payne, rose, is a very strong variety carrying twelve fine blooms. Others very good are John Farwell, deep crimson red; L'Ami Etienne, full round incurved Japanese, colour of Madame C. Audiguier, but broader florets; and President Borel, deep rose, drooping florets. Queen of the Hirsutes is chestnut red, and F. W. Flight is rather late, but coming good.

Some older varieties, such as Mdlle. Marie Hoste, M. E. Carrière, Louis Boehmer, Edwin Molyneux, and Felix Cassagneau are grown, but Mr. Burt is very severe in his selection, a collection of which any man might well be proud.—C. ORCHARD, Bembridge, I.W.

MESSRS. J. VEITCH & SONS, CHELSEA.

THE nursery of Messrs. Jas. Veitch & Sons at Chelsea is, as everyone connected with horticulture well knows, always worth a visit, and now. when the Chrysanthemums are in bloom, perhaps more so than ever. The house in which the plants are shown is a large span-roofed one, the same as was utilised last season; the arrangement being also similar, a central bank, with narrow borders on each side. Most, if not the whole, of last season's novelties are to be seen, every endeavour having been made to keep the collection well abreast of the times. It is the general opinion of those who have seen the flowers that they surpass those of last season. This will doubtless be considered high praise by those who saw the magnificent examples last year, and who have not yet paid a visit this season; but, neverthcless, it is well merited, as all must acknowledge when they see the flowers. The plants are models of good management, and much credit is due both to the firm and the able grower, Mr. Weeks. The Japanese varieties are in full bloom, the incurved being a few days later. Careful attention has been devoted in placing the plants so that the colours would blend harmoniously, and the effect from the door of the structure is eonsequently striking, which attracts the attention of those who are passing down the walk through the nursery.

Immediately on entering the house a flower of Colonel W. B. Smith is prominent, measuring, with the florets hanging down, 22 inches in circumference. Not so large but equally as striking are blooms of Miss Anna Hartshorn and the dark coloured Wm. Seward, one of the latest introductions, and decidedly an acquisition amongst the very deep crimson varieties. Bouquet des Dames is seen in superb form, the blooms being exceptionally deep and handsome. Edwin Molyneux here, as at many other places this season, is good, as also is Earon Hirsch, a bronzy yellow incurved. There are several plants of Viviand Morel, almost all of which are earrying large shapely flowers. Mons. R. Bahuant is admirably represented, the same remark being applicable to Mrs. C. E. Shea and L'Automne. Amongst the hairy petalled varieties Louise Boehmer and W. A. Manda are carrying by far the best blooms, this being more especially the case with the former. The now popular Beauty of Exmouth is to be seen in grand shape and fine substance, and is certainly one of the best whites extant.

A superb deep rosy pink is found in Mrs. C. Harman Payne, additional beauty being given to the plant by the white-tipped florets. One of the newest introductions is J. Shrimpton, Japanese, which, besides having fine deep velvety crimson petals, is of a dwarf habit, which will doubtless be a great recommendation to some growers. An ivory white variety of a high order of merit is Mdlle. Thérèse Rey, the blooms of which are of almost perfect shape. G. C. Schwabe carries highly ereditable flowers of a pleasing rosy carmine colour. Miss Dorothy Shea will not readily be superseded amongst the charming terra cotta shades, as the substance is all that could be wished, and the shape practically faultless. Chas. Davis is a fine bronze yellow variety of the true Viviand Morel type. The blooms of the grand yellow W. H.

Lincoln are magnificent, as also are those of Florence Davis and Mons. W. Holmes. Amongst the many varieties which promise to be of exceptional merit are J. Stanborough Dibben, the superb Lord Brooke, Mdlle. Marie Hoste, and Robt. Owen, a very fine incurved Japanese of a deep bronzy yellow shade. With these the list must be closed, but it should be borne in mind that only a few out of the many excellent varieties have been mentioned, and those persons who will come to London to see the various Chrysanthemum shows cannot do better than devote an hour amongst the Chelsea plants; it will, as everyone who goes will afterwards say, be an hour well spent, and well worth any little inconvenience or trouble it may cause.

MESSRS. CANNELL & SONS.

The great Swanley growers have a very fine display this year, their large house, which is 150 feet long and 25 wide, presenting a very beautiful appearance. The plants form a broad central and two narrower side banks, and the principal one is broken up by handsome Musas and other foliage plants which throw the colours into bold relief. The Chrysanthemums are admirably grown, good culture setting its mark on them, as well as on everything else at the Home for Flowers, and all the most noteworthy of the newer varieties are represented,

together with a large number of seedlings.

The increasingly popular incurved Japanese section is materially strengthened by Duke of York, a large deep flower showing a pink reverse. The white Japanese, Beauty of Exmouth, is chaste and pleasing, and only lacks depth to make a grand sort. Wm. Seward is one of the features of the collection, this grand Japanese being in splendid condition. The difference between flowers on the crown and terminal buds is very marked, those on the latter being deeper in colour and with more slender florets than the others. Without question it is a great acquisition. A very large Japanese named M. Fernard Bertin, tinted with rosy lilac, is highly promising. The beautiful bronzy Japanese, Colonel Smith, is too well known now to need description. Messrs. Cannell have grafted it on Chrysanthemum Halleri maximum, as suggested by the accomplished Belgian horticulturist, Mr. Everaerts, in the Journal last spring. Good bushes have been secured by grafting in March, and it is noteworthy that the flowers on the grafted plants do not damp like many of the others, owing perhaps to the smaller amount of water required by the stock. There are several excellent decorative varieties, such as Miss Watson, a yellow Japanese; the old, but still useful Elsie, Eynsford White, Gold Mine, and Golden Ball.

International, a rosy lilac Jap fading to creamy white, is noteworthy for its great size; Madame Edouard Rey, a soft pink with very broad florets, incurving on the second bud, is a very promising Jap; and so is Eda Prass, soft blush, very large and full. A good incurved does not turn up so frequently as a good Jap, but there is one in Globe d'Or, a bronzy yellow with very broad petals, and another in the bronze Baron Hirsch. A white of this section named Madame Chataing, raised by Calvat, is very promising. A new white Japanese seedling named Amy Chantler, which has extremely long florets, may fill up into a good flower. Commandant Blasset has done so already, being full, well formed, and fine, colour rosy crimson; Lord Brooke, the incurved Jap which aroused so much attention last year, is coming well, and with very deep colour, showing deep reddish bronze; Primrose League, a light yellow Jap, is extremely good; and so is G. W. Childs, its colour being very rich. Such old favourites as W. Tricker and Viviand Morel, for such they now are, hardly need mention, for their qualities are familiar. The yellow Viviand, Chas. Davis, is represented, and is varying curiously in colour, some flowers being clear yellow, others fawn, and others again suffused with lilac. But what promises to be a still greater acquisition is Mdlle. Thérèse Rey, a Japanese with florets as broad and substantial as those of Marie Hoste; it is white, save for a yellow shading in the centre. Another grand novelty is J. Shrimpton, a Japanese with wonderfully rich crimson flowers, and a thoroughly good grower; Striped Odorata, a sport from La Triomphante, lilac striped, is pleasing; and last may be mentioned a Jap named Vice-President Calvat, a bronzy very deep flower, and carrying splendid foliage.

It is noteworthy that the collection is much dwarfer this year, a

It is noteworthy that the collection is much dwarfer this year, a result brought about no doubt by the effects of the weather, combined with the multiplication of dwarfer sorts than those which used to rule. It is a very gratifying fact. A visit to Swanley is well repaid just now, for in addition to this grand display of Chrysanthemums, the Zonal Pelargoniums and winter Begonias are in splendid bloom.

MESSRS. J. LAING & SONS, FOREST HILL.

Chrysanthemums are well represented at the nurseries of Messrs. J. Laing & Sons this year, and the firm justly maintains the good reputation they have long had in this respect. Whilst many of the better varieties are staged in a large span-roofed structure at the Stanstead Road Nurseries, it must not be supposed that these constitute the whole of the stock. At the Vineyards, Catford, there are several long houses filled with Chrysanthemums in excellent condition. All the best varieties are grown, and these now make a grand display. The plants are noticeable for their robust appearance, and the flowers are obviously of no ordinary character. Whilst keeping abreast of the times, the principal point in view here is to grow only the best of the numerous varieties that are now in existence, and to do these well. That this object has been attained no one who pays a visit to Messrs. Laing's nurseries can doubt.

When a call was made last week many of the Japanese varieties were expanding some splendid blooms, and by the present time they will

be in prime condition. The pretty salmon pink reflexed Japanese variety Eda Prass is exceptionally good, and so is Charles Davis, the new sport from Viviand Morel. Some splendid examples of Col. W. B. Smith are grown, and the white Louis Boehmer, known also as Enfant des Deux Mondes, is a worthy representative of the hirsute family. Golden Wedding is seen in fine order here. This is a splendid Japanese variety with large blooms of a rich golden yellow. Miss Dorothy Shea (J) is a flower of good form and colour, and Miss Muriel Scott may be described as a really good light yellow, similar in build to Etoile de Lyon. Primrose League is very fine with its large creamy white graceful flowers, and Princess May, a Japanese variety of merit, is well grown. William Seward is in excellent condition with its magnificent richly coloured blooms, and the exquisite form of Vicomtesse Hambledon is noticeable. The last named is an incurved Japanese of a large size and silvery pink colour. Rose Laing still retains a prominent position on account of its usefulness, and F. W. Flight is deserving of notice. The last named is a reflexed Japanese variety, crimson florets and a golden reverse. Eugène Farez is another of the same type with crimson red flowers, and Duke of York is an incurved Jap of a deep pink shade. This is a dwarf grower but possesses a strong constitution. The popular Stanstead White still retains a first position, and amongst others such as W. H. Lincoln, W. H. Atkinson, Middleton Clarke, and Miss Maggie Newton are conspicuous.

Although less extensively grown, perhaps, than the Japanese the best of the incurved varieties command attention, and fine blooms of these will be now developing. Mons. R. Bahuant we noted as being particularly fine, and the same applies to Baron Hirsch, considered by some to be the finest incurved in cultivation. Mrs. J. Mitchell, a sport from Empress Eugénie, is a splendid variety of a golden amber tint. Mrs. Robinson King is likewise good, the same applying to other standard

varieties.

MR. H. J. JONES, RYECROFT NURSERY, LEWISHAM.

ALTHOUGH but three or four years have elapsed since Mr. H. J. Jones established himself at Ryecroft Nursery, Hithergreen, Lewisham, he has by characteristic perseverance built up a business that, so far as Chrysanthemums are concerned, is practically unsurpassed. This enviable position in the Chrysanthemum world is due solely to the exceptional capacities displayed by Mr. Jones, his extensive knowledge of the "Autumn Queen," and the unceasing manner in which he has striven. From early morning till late at night this enthusiastic grower, aided by his estimable partner in life and assistants, may be seen busily engaged amongst his plants, and thus a Journal representative found him last week. The result of this continuous labour, as before hinted, is a magnificent collection of the best varieties, including the latest novelties and numerous new seedlings of merit not yet in commerce.

The plants make an imposing display, even at this early period, and by the middle of November the spectacle will be well nigh beyond description. It is not an easy matter, however, for anyone to form an adequate idea as to the magnitude of the Ryecroft collection without paying a visit, but a few facts will show that it is of no ordinary dimensions. Nearly 10,000 Chrysanthemums for providing large blooms are grown, and in addition to these there are 18,000 plants in 6-inch pots. Then we find 2000 plants of the early howering varieties, of which a speciality is made. These, however, were not sufficient, and ever on the alert for making further progress, Mr. Jones last week purchased by private contract the whole of Messrs. Pitcher and Manda's European stock of Chrysanthemums, comprising some 3000 plants, including many choice American seedlings. These have been removed from Swanley to Ryecroft Nursery at a cost of £40, and the two collections make a display of a unique character. The principal show house is 104 feet long by 24 feet wide, a splendid span-roof structure, lofty, and well ventilated. In this no less than 4000 well grown plants are most admirably arranged. Instead of the customary straight path and formal crowded masses of blooms, the plants are placed so that a winding walk is made through the centre of the structure, the Chrysanthemums on each side forming a charming undulating surface of varied colouration. Apart from the house mentioned there is another huge structure of similar dimensions filled to the utmost with well grown plants of choice varieties. Thousands of homeraised and foreign seedlings are on trial in pits and frames, and it is obvious that from these some magnificent varieties will be forthcoming.

Regarded individually the blooms on the plants in the exhibition houses are remarkable for their size and colour, comprising all the latest novelties. The Japanese forms are especially good, and the incurved varieties are showing wonderfully well. Space will not permit us to enumerate other than some of the new varieties, but whilst these are so much in evidence it may be taken for granted that the standard choice kinds are similarly well grown. Amongst the novelties of this year The Tribune takes a prominent place. Mr. Jones has already secured two certificates for this charming Japanese variety, and from a bloom grown by him the illustration (fig. 59) on page 403 has been prepared. The flower is very large, of good build, with broad and long florets of a soft primrose colour. For exhibition purposes this is likely to prove a useful variety, the plant being also dwarf in growth. Pearl Beauty is a beautiful incurved Jap, with long pearly white florets, and Primrose League is destined to take a foremost position. The last named is very large and of graceful appearance. Charles Blick, which was raised at Lewisham, is grand golden yellow Japanese, and another of Mr. Jones' seedling, W. H. Atkinson, is in splendid condition. G. W. Childs is the best scarlet crimson of the year, and a decided improve-

ment on J. Shrimpton. President Borel, which has been certificated this season, is a handsome Japanese variety, striking purple colour and golden reverse. C. Shrimpton, as seen at Lewisham, is a magnificent bloom of E. Molyneux type, and one that is sure to find favour, and the same applies to Madame Charles Molin. The last named will prove better than the so-called white Viviand Morel. Beauty of Exmouth is splendidly grown, and so is Ryecroft Glory, a rich yellow reflexed variety, useful for decorative purposes. Mrs. Dreer is an American seedling of the old Bouquet Fait type, but much better, and J. H. Taylor is a heautiful bloom of large size role with a white section. beautiful bloom of large size, pale pink with a white centre. President W. R. Smith is one of the best Japanese varieties of the season, being massive in build and of a fine pink colour. It is thought that this variety will, for exhibition purposes, displace many other pink kinds which are now grown. Numerous others are strongly represented, especially such popular varieties as Charles Davis, Mrs. Harman Payne, Madame E. Rey, Miss Dorothy Shea, Baron Hirsch, Lord Brooke, and Colonel W. B. Smith.

As before mentioned, Mr. Jones is exceptionally strong in seedlings, and is in the possession of many grand varieties, about which something will be heard later on. Mrs. Charles Collins, he considers, is a variety of the future. This is an incurved Japanese of a large size, full flower, long florets, colour flesh passing to white and slightly tinted pink. Seedling 242 is a very fine Japanese, and so is H. H. Spencer. Seedling 401 is a splendid incurved Jap, white with a pale yellow centre, and amongst the one thousand seedlings raised by Mr. Jones are many others that deserve more than a passing reference. The hirsute-petalled types are now plentiful, there being several new varieties. One named

Hairy Wonder, a curious flower of a bionzy yellow shade, is very striking, and the same may be said of "Sautel 1893," an incurved Japanese, florets very hairy, colour rosy amaranth with silvery pink reverse. Mr. Wm.

Trealease is a decided improvement of Louis Boehmer. Mrs. Dr. Ward is perhaps one of the finest hairy petalled varieties now in the finest hairy-petalled varieties now in cultivation. This is a full and deep flower of bronze yellow shade, tips and outer florets shaded rcd. Other hirsute varieties include W. A. Manda and the white Louis Boehmer. All the latest novelties of merit in the other sections are likewise grown, and it may be of interest to add that plants of some of the New Zealand varieties that were exhibited in ice at the Royal Aquarium last year, may now be seen carrying blooms at Ryecroft Nursery.

CHRYSANTHEMUMS AT EXMOUTH.

THE headquarters for Chrysanthemums in the West of England is the Claremont Nursery. Japanese varieties have most attention, and some hundreds of novelties are on trial. As the birthplace of the celebrated Beauty of Exmouth, this variety is naturally very much in evidence, being represented by about a hundred well-grown plants carrying handsome blooms. The largest bloom in the whole collection is Prim-

rose League. This variety is of good habit and produces large blooms of a delicate straw colour. Duchess of Devonshire varies in tint of colour the same as Viviand Morel and other of this class; many blooms are almost white and others of a rosy magenta. Col. Smith is represented by some handsome blooms. Eda Prass, for which Mr. Godfrey was recently awarded a first-class certificate, is of delicate salmon pink, the blooms being very deep and solid. The immense blooms of Mrs. Harman Payne are very striking in colour, which is rosy magenta with a light reverse. Incendie is a fine addition to the Japanese incurves; the blooms are light red with a rich golden reverse, very deep in build. Robert Owen is a very good bronzy yellow, but apparently would expand in better form with a little more heat. Charles Blick is a decided advance on Boule d'Or and others of this class. Chas. Davis, the "yellow" sport from Viviand Morel, is represented by rich bronze bloom. Miss Dorothy Shea is a very fine drooping flower of a deep mahogany colour. Golden Wedding will also find a place among the first twenty-four. The blooms are of large size, good in form, of a rich buttery yellow.

Wm. Seward, the dark blooms of which contrast well with the light varieties, is here well grown. G. W. Child is giving good solid blooms a shade or two lighter than Wm. Seward, but with a buff reverse. The white Louis Boehmer is similar to its parent, except the colour, which is of a milky white. Lord Brooke is not of the first size, but the bronzy incurved blooms are very striking. Miss Libbie Allen is almost identical in shape, but is a clear lemon yellow, and of more sturdy growth. Robert Flowerday is very distinct, the blooms are of a rich purplish lake with a silvery reverse; habit of plant robust and sturdy. The foregoing list does not by any means exhaust all the good varieties to be found in the Claremont Nursery, but, whilst bearing in mind the great advance that has recently been made in Japanesc, yet

those mentioned are likely to come to the front as sterling varieties.

Among the curious or novel kinds is Novelty, deep rosy purple, in form very similar to an Endive; also Délaux Pilars, in colour a rich brown; in fact, the tint now so very fashionable. This is one of the hirsute section, and is certainly the most hairy up to date.

Several seedlings raised in the nursery are being tested by Mr.

Godfrey. The most promising is a very large and handsome pink named Devoniensis. This in form is very striking, the florets are long and drooping, gracefully recurving at the tips. Another is Exmouth White, something after Beauty of Exmouth in form, but of the purest white.—A N.C.S. MAN.

CHRYSANTHEMUM SHOWS.

HAVANT.—OCTOBER 27TH AND 28TH.

THE tenth annual Exhibition was held in the Town Hall on the dates named. Cut bloom classes occupied the most important ipart of the schedule, the principal class being that for thirty-six distinct varieties, half Japanese and the remainder incurved. Mr. Penford, gardener to Sir F. Fitzwygram, Bart., M.P., Leigh Park, Havant, managed to win

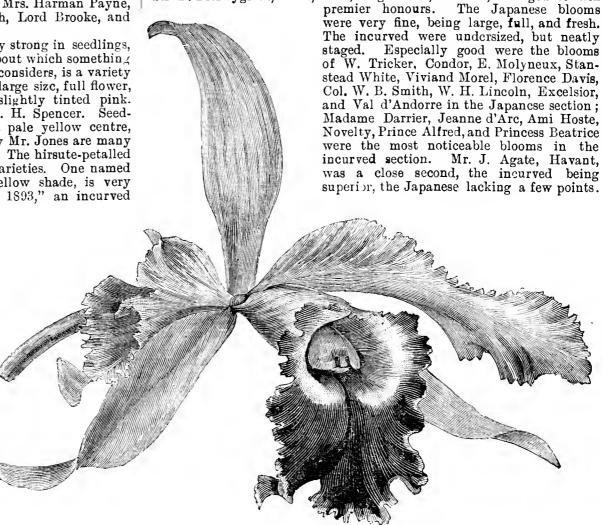

FIG. 60.—LÆLIO-CATTLEYA PISANDRA. (See page 391.)

Charles Davis, Madame Octavie Mirbeau, Col. W. B. Smith, Amos Perry, and George Savage, with Mrs. Heale, Mons. R. Bahuant, and Prince Alfred were the best blooms.

For eighteen blooms, distinct, nine to be Japanese and the remainder incurved, there was a spirited competition. Mr. C. J. Steptoe, gardener to G. A. Gale, Esq., Horndean, was an easy first. E. W. Clark, to G. A. Gale, Esq., Horndean, was an easy first. E. W. Clark, Marquise de Paris, Excelsior, Viviand Morel, Lord Wolseley, Miss M. A. Haggas, and Mons. R. Bahuant were the best blooms. Mr. J. Suter, gardener to J. Lascelles, Esq., Havant, was second. Mr. Penford was first for twelve Japanese with large, richly coloured examples of the leading kinds; Excelsior, Marquise de Paris, Col. W. B. Smith deserve a special mention. Mr. Agate was a good second. Mr. A. W. Howard, gardener to E. G. Boucher, Esq, Sennicotts, Havant, was third. Mr. Penford was again successful, this time in the class for twelve incurved, with medium-sized, neat blooms. Mr. Agate was second.

Three splendid stands of twenty-four Anemone blooms were staged, Mr. Penford gaining premier award with an even, fully developed collection, Sœur Dorothée Souille, M. C. Lebocqz, Jeanne Marty, Sabine, and Duchess of Westminster were especially well represented. Mr. Agate was a close second, and Mr. Steptoe third. Mr. Penford was again successful for twelve blooms of reflexed varieties, staging large and solid examples of leading kinds, Felicity, Phidias, King of Crimsons, Emperor of China, and Chevalier Domage were especially noteworthy.

Messrs. Steptoe and Agate followed in the order named.

Pompons made a bright display. For twelve sprays Mr. Agate was an easy first, staging well-developed blooms of leading varieties. Mr. H. Brown, gardener to J. Taplin, Esq., Havant, was second. Single-flowered varieties are always well shown at Havant, and this year they were better than usual. For twelve the last-named exhibitor won with fully developed blooms of telling sorts most excellently arranged. Mr. Agate was a good second. In this stand a new variety named Pattie Penford was staged; the florets are deeply reflexed, pure white, with a pale green disc. Mr. Penford secured the prizes for premier blooms—incurved and Japanese—Madame Darrier and Col. W. B. Smith. In the class confined to amateurs and single-handed gardeners Mr. Holmes,

Gosport, won first prize for twelve Japanese with a splendid stand of blooms, almost equal to the best in the Show. Groups of Chrysanthemums were not numerous, but that from Mr. J. Agate contained finc blooms, lightly arranged, and the premier prize was awarded. Mr. J. Suter was second.

Primulas, Solanums, and table plants were well shown, and fruit and vegetables were of commendable quality. Table decorations by ladies only was a distinct feature of the Show, the prizes falling to Miss Newman, Mrs. A. Stubbs, and Mrs. Conway in the order named, all having effective arrangements.

LOUGHBOROUGH.—OCTOBER 28TH.

THE nineteenth annual Chrysanthemum Show was held in the Town Hall on October 23th. The Exhibition was up to the standard of former years in everything but the incurved blooms.

poorly represented, being very rough. Japanese blooms were well shown.

Messrs. Biddles & Co. took first prize in the group of Chrysanthemums, most of the plants having flowers fit for staging in the cut bloom section. The same firm took first prize for a group of foliage and flowering plants; but all the groups were too formally arranged. Primulas and dinner table plants were in good condition. Grapes were well shown, as also were Apples and Pears. Collections of vegetables shown by cottagers were excellent, and finer Celery has scarcely ever been seen.

There was a very good collection of vegetables not for competition,

also a display of Orchids, both of which received certificates.

There were also prizes given for the best specimens of writing, freehand drawing, and needlework, open to the scholars of the Loughborough school.—J. L. B.

PORTSMOUTH.—OCTOBER 31st, NOVEMBER 1st AND 2ND.

This great southern exhibition was one of the best yet held. The Drill Hall in which the show took place affords ample space for the exhibits and for the numerous company which attend this Exhibition. The arrangements, as usual, were perfect in the hands of an efficient Committee, guided by the Hon. Secretary, Mr. F. Power, and his assistant, Mr. B. Miller.

Cut blooms formed the most attractive part of the Exhibition. The principal class was that for forty-eight blooms, half to be Japanese and the remainder incurved, in not less than eighteen varieties of each section, and not more than two of one variety. No less than seven competed, making a very fine display. Messrs. W. & G. Drover, The Nurseries, Fareham, won the premier position with large, well developed Japanese, well staged. The incurved were of medium size, but neatly finished. The names were—Japanese: Col.W. B. Smith (2), Charles Davis, W. Seward (2), Stanstead White, Mrs. F. A. Spaulding (2), Gloire de Rocher, Viviand Morel (2), E. Molyneux (2), Sunflower (2), Mrs. C. Wheeler, W. H. Lincoln, G. C. Schwabe, Excelsior, Amos Perry, Puritan, Alberic Lunden, W. Tricker, and Lord Brooke. Incurved: Empress of India, Madame Darrier (2), Queen of England (2), Baron Hirsch, Lord Alcester, Lord Wolselcy (2), Jeanne d'Arc (2), M. Jules Barigney, Prince Alfred, Alfred Lyne, Alfred Salter, Princess Beatrice, Lady Hardinge (2), Nil Desperandum, John Doughty, Novelty, Refulgens, Brookleigh Gem, and a seedling. Mr. N. Molyneux, gardener to J. C. Garnier, Esq., Rooksbury Park, Wickham, was a good second. The incurved were more regular in size, but the Japanese were a trifle smaller. Especially good were G. C. Schwabe, Mdlle. Marie Hoste, Charles Davis, Sunflower and Mrs. C. H. Payne, while Princess Beatrice, Violet Tomlin, Ami Hoste, Golden Empress, and Lord Alcester were noticeable in the incurved section. Mr. G. Inglefield, gardener to Sir J. Kelk, Bart., Tedworth, Marlborough, third; and Mr. Penford, gardener to Sir F. Fitzwygram, Leigh Park, Havant, fourth.

The next important class was that for twenty-four, distinct, half the next important class was that for twenty-four, distinct, half incurved and the remainder Japanese. Mr. Inglefield here secured the premier award with a very fine stand. The incurved blooms were perhaps the best in the Show. The names were Lord Wolseley, Golden Empress, Madame Darrier, Emily Dale, Jeanne d'Arc, Baron Hirsch, Princess of Wales, Empress of India, Prince Alfred, Lord Alcester, Lucy Kendall, and Miss M. A. Haggis. The Japanese were Mrs. C. H. Payne, W. H. Lincoln, Viviand Morel, Col. W. B. Smith, E. Molyneux, Sunflower, W. Seward, Gloire dc Rocher, Mrs. Falconer Jameson, W. Tricker, and F. Davis. Mr. H. J. Parrott, gardener to Mrs. Kincaid, Smith, Wood W. Seward, Gloire de Rocher, Mrs. Falconer Jameson, W. Tricker, and F. Davis. Mr. H. J. Parrott, gardener to Mrs. Kincaid Smith, Wood End, Chichester, was a good second; and Mr. N. Molyneux third. Six competed in the class for twelve Japanese, distinct, and Mr. C. H. Holloway, gardener to F. W. C. Read, Esq., The Wakes, Selborne, won the premier award with a stand of heavy blooms. Mr. H. Parrott was second, and Mr. Penford third, both staging creditably. Four competed in the class for twelve distinct incurved. Mr. Penford won with medium-sized examples of leading varieties. Mr. J. Hughes, gardener to W. Baring, Esq., Norman Court, Salisbury, second; and Mr. C. J. Steptoe, gardener to G. Gale, Esq., Horndean, third.

The class for reflexed in twelve blooms, not less than eight varieties, showed a falling off as compared to past years, six only competing. The best blooms came from Mr. Penford, who had well-developed flowers of King of Crimsons, Phidias, and Felicity. Mr. Steptoe was second, and Mr. S. Dee, gardener to Mrs. Mills, Kingston, third. The Anemone section produced a keen competition, the flowers being good in all the six stands of twelve blooms. Messrs. Agate and Hatch, the latter gardener to the Victoria Park's Committee, Portsmouth, won first and second honours; and Mr. Penford was third.

Pompons made a bright and varied display. Mr. H. Lee, Moreland's

Road, Gosport, won with twelve bunches. Mr. Hatch second, and Mr. Agate third. A class was provided for the fimbriated section, in bunches of three blooms to a bunch, and they made a fine display, cut with from 9 to 12 inches of stem and leaves. Mr. Hatch was a distinct first prize winner, Chardoneret, Crœsus, Scapin, and Massange were really fine. Mr. Adams, gardener to T. S. Edgecombe, Esq., Hinton House, Southsea, was second. Single flowered kinds were also well staged in bunches of three blooms each. Of six exhibits that from Mr. Brown, gardener to J. Taplin, Esq., Havant, was first; Mr. Agate second, and Mr. H. Lee third.

For six Japanese, any one variety, Mr. C. Holloway staged Edwin Molyneux, very fine, and easily won the first prize amongst seven competitors; Mr. Hughes with Avalanche coming next, while Sunflower from Mr. T. Wilkins, gardener to Lady Theodora Guest, Inwood House, Blandford, secured a third place. In a similar class for incurved Mr. Inglefield staged Jeanne d'Arc in fine condition, and won the premier award. Mr. Hughes was second with Lord Wolseley, and Mr. Agate

third with Madame Darrier.

Messrs. Perkins & Sons, Coventry, with one of their usual arrangements, won first prize for a bouquet of Chrysanthemums and Ferns; Mrs. F. Mills, 13, Florence Road, Southsea, was second. For the best dressed glass stand with Chrysanthemums and other flowers there was a brisk competition, no less than ten competing. Mrs. Conway, Havant, won the premier award with a light arrangement of suitable flowers. Miss Kate Golding, 24, Winchester Road, Southampton, was second. An arrangement of autumn foliage and berries in an epergne brought out five competitions. Mrs. Conway was again successful; Miss C. Winch, Gosport, second. On a table space of 3 feet each way prizes were offered for the best arrangement of Chrysanthemums with any kind of foliage. Here Mrs. Conway again asserted her superior taste by winning first place with a charming arrangement. Miss Kate Golding second.

Plants made a good display down the centre of the Hall and across one end. For six trained specimens, Mr. Penford won; Mr. G. Lambert, Bognor Road, Chichester, was second. For twelve plants in 9-inch pots Mr. Lambert won, as also he did for a single specimen of any variety, staging Mr. G. Rundle fully 4 feet in diameter and freely flowered. Mr. Penford followed with Elsie. Mr. Lambert also had the best Pompons in eight varieties, freely flowered examples of popular kinds.

Groups of Chrysanthemums only and those interspersed with foliage plants made a bright display across one end of the hall. In the former class Mr. Hatch won, showing well grown examples, not too formally arranged. Mr. Lambert was second. In the latter class Mr. W. Rooke, gardener to Messrs. Brickwood & Co., Southsea, was first. Mr. E. R. Harvey, Portsea, was second.

Table plants made a fine display. Mr. A. Payne, gardener to Mrs. Ewald Smith, The Oaks, Emsworth, won with twelve plants. Primulas and Solanums were well exhibited.

and Solanums were well exhibited.

Fruit was surprisingly well shown. For three bunches of Black Grapes Mr. Hall, gardener to S. Montagu, Esq., South Stoneham, won first prize, staging Alicante, good in every respect. Mr. J. Knight, gardener to H. Harding, Esq., The Retreat, Southsea, was second, and Mr. Warden, gardener to Sir F. Bathurst, Clarendon Park, Salisbury, The last named won for three bunches of any white variety with Muscat of Alexandria. Mr. J. Parrott, with Alicante in prime condition, won with two bunches any black Grape, Mr. Agate second. The class for thirty dishes of Apples, distinct varieties, produced a fine display. Mr. J. Watkin, Pomona Farm Nursery, Withington, Hereford, was placed first with a splendid collection. Mr. G. Goldsmith, gardener to Sir E. G. Loder, Bart., Horsham, was second, and Mr. J. Scott third. Mr. Watkin followed up his previous success in the class for twenty dishes of Pears with fine fruit. Mr. Goldsmith was second, and Mr. Goodacre, gardener to the Earl of Harrington, Elvaston, Derby, third. Mr. Goldsmith won with sixteen dishes of Apples and eight dishes of Pears with splendid fruit. Many other excellent dishes were staged; but limited space forbids a mention of them individually. Vegetables also made a great display.

Mr. H. J. Jones, Ryecroft Nursery, London, had eleven dozen cut blooms of Japanese Chrysanthemums "not for competition," including the many choice novelties he now has; this stand attracted the attention of many visitors. Messrs. Edwards & Son, Sherwood, Nottingham, had a display of their vases, stands, baskets and epergnes

filled with Ferns.

KENT COUNTY .- NOVEMBER 1ST AND 2ND.

THE sixth annual Exhibition of the Kent County Chrysanthemum Society was held in the Rink, Blackheath, on the above dates. as a whole, the Show compared favourably with those held on previous

occasions, the cut blooms being particularly good.

For eighteen Japanese and the same number of incurved blooms, distinct, Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley, Croydon, was first. The Japanese varieties staged were fresh and clean, and were as follows-Mdlle. Therese Rey, W. Seward, Anna Hartshorn, W. H. Lincoln, G. C. Schwabe, W. Tricker, E. Molyneux, Florence Davis, J. Shrimpton, Mdlle. Marie Hoste, President Borel, Mrs. F. Jameson, Viviand Morel (grand), Eda Prass, Sunflower, Mrs. G. W. Adams, Col. W. B. Smith, and Avalanche. The incurves comprised Queen of England, Vice-President Jules Barigney, Hero of Stoke Newington, Madame Darrier, M. Martegnac, Refulgens, Empress of India, Princess of Wales, Mrs. Heale, Prince Alfred, Baron Hirsch, Novelty, Mons. R. Bahuant, Lord Alcester, Madame F. Mistral, Lord Wolseley, Jeanne d'Arc, and Violet Tomlin. Mr. Leadbetter, gardener to A. G. Hubbuck, Esq., Elmstead Lodge, Chislehurst, was second, and Mr. P. Waterer, Fawkham, Kent, third, both exhibitors staging well-

grown blooms.
